In the Soviet army the mechanized and armoured divisions which in 1947 were outnumbered 2 to 1 by the infantry divisions were thought to have approached parity with the latter in the mid-1950s. In all types of Soviet divisions, however, there was a new integration of infantry, tanks and self-propelled artillery into smaller groupings. Until 1958 Great Britain retained the "triangular" division which came out of World War II, with three composite brigades, each comprising one armoured regiment and three infantry battalions, and each brigade supported by one light artillery battalion and one medium artillery battery. This division was air-transportable except for its tanks and medium artillery. In 1958 the British decided to make the brigade group the basic formation instead of the division. The British army thereafter consisted of armoured and infantry brigade groups. Divisional headquarters were retained where necessary and had under them a varying number of armoured or infantry brigade groups. In France, reorganization begun in 1955 developed the *Régiment Inter-armes,* a small regiment combining tanks, riflemen, antitank guided missiles and 120-mm. heavy mortars. This type regiment was used in the *Division Mécanique Rapide* and was extended to infantry divisions as well. In the United States the name "pentomic" was coined for new types of airborne, infantry and armoured divisions organized for employment in either atomic or conventional war. The first pentomic division, the 101st airborne, was organized in the mid-1950s with plans for all U.S. divisions to eventually take this form. The strength of the new airborne division was reduced from 17,000 men to about 11,500. The organization was pentagonal with five battle groups, each with five infantry companies and a heavy mortar battery, five 105-mm. howitzer batteries, a battery of 762-mm. Honest John rockets, an engineer battalion, a signal battalion, a command and control battalion and a support group to handle supply and maintenance. The new infantry division had the same pentagonal arrangement of battle groups but more divisional artillery. The latter was divided into a battalion of five 105-mm. howitzer batteries and a battalion containing the heavy fire support; *i.e.,* two 155-mm. howitzer batteries, a battery of 8-in. howitzers and a battery of Honest John rockets. This infantry division contained tanks only in its reconnaissance battalion and numbered 13,750 men instead of the original 17,455. The pentomic armoured division looked much like its immediate predecessor using four tank battalions and four armoured infantry battalions, each with four companies. As part of the pentomic reorganization, the U.S. army included Army missile commands, ranging in size from 1,200 to 5,000 men, which were built around the Honest John rocket and the Corporal ballistic-type guided missile. These missile commands were capable of attachment to U.S. armies and corps, or could be used in support of allied armies lacking integrated atomic fire capability.

With these reforms and a continuous advance in its integral air mobility, it was felt that for a permanent establishment in the United States and overseas a regular army of 1,000,000 men would suffice, provided there was a highly professional standard of skills in new technologies and that ready reserves for the army's ultimate support in the field could be assured continuous training.

There remained, however, in many minds a suspicion that the new warfare would require forms of defense markedly different from those of the army program. This suspicion was strengthened by the announcement of the U.S.S.R. in 1955 of its intention to reduce by nearly one-third the Soviet Union's immense army of, by report, 4,000,000. Exploited by Moscow spokesmen as evidence of the U.S.S.R.'s disposition to reduce armament, the proposed 1,200,000 drop was interpreted abroad, variously, as resulting from a desire to enter more workers in industry, from a readiness to reduce garrisons in Asia as permitted by the new Chinese alliance (itself adding perhaps 4,000,000 disciplined troops to world communist resources) or from a professional judgment that the new warfare would engage missiles rather than masses of infantry. The last of these views was already widely held elsewhere; the United States defense establishment had re-evaluated manpower requirements and had sharply reduced the numbers in army and navy while pointedly increasing those services' total firepower, thanks to the new weapons. Great Britain at the same period was cutting the size of its forces, and smaller powers of western Europe, which had only lately built up their military units under their obligations to the North Atlantic Treaty organization, were either reducing them in numbers of active divisions or reducing the period of individual conscription and training—partly by reason of increased firepower per unit, but more by a subsidence of their earlier alarm over Soviet intentions. From whatever reasoning, the mid-1950s disclosed a strong trend among world armies in general toward greatly increased reliance upon the deadlier weapons, with a lessened zeal for numerically large establishments.

Army planning, in this case enveloped in a good deal of secrecy, included also that for advanced technologies in chemical, biological and radiological (CBR) warfare. (*See* BIOLOGICAL WARFARE; CHEMICAL WARFARE.) It had become apparent that terror weapons could be potent as well as terrible. These included gases far more lethal than those used in World War I, yet in some cases so quickly dissipated that, in theory, the aggressive forces would be able to move forward briskly into an area whose defenders were gone but whose buildings and highways were usable by the occupying forces, there having been no attack by explosives or incendiaries. Biological warfare might introduce poisons as well as disease germs to food or water supplies; radiological assault would be a by-product of atomic attack. So great was public revulsion against these methods that their proponents worked largely in secrecy, protesting that they had to develop these arts in order to understand how to devise countermeasures and also in order to have CBR warfare techniques ready for instant use in retaliation against their prior employment by an enemy. The principle of deterrence, in brief, was applied here, precisely as in the case of nuclear weapons.

At the same time there was intensive research among the world's armies into readaptations of conventional techniques. The U.S. army in 1961 experimented with a new and, it was hoped, more flexible divisional structure (*see* DIVISION, MILITARY) consisting of a common division base and three tactical brigades containing variable mixtures of combined arms. New weapons and detection systems seemed to rule out future amphibious operations exposing vast forces to possible annihilation. Dispersal of matériel also demanded ingenuity in devising workable installations and encouraged the use of light, high-speed transportation equipment to permit swift concentration and dispersal. These were the necessary instruments of a new warfare for armies as contemplated in the mid-20th century, which called for swift raids and withdrawals and for persistent and piecemeal demoralizing harassment of an enemy rather than fixed lines and massive clashes.

But always the new warfare called for missiles of varying capabilities—those of long, medium and short range, of low and high trajectories (each of value in defeating enemy detection and interception)—and for maximum mobility of the missiles' launching apparatus, whether the target should be on the ground, in the sea or in the air. The great advances in the technologies of nuclear fission and fusion, of rocket propulsion and of electronic guidance, had combined to transform the characteristics of armies and the thinking of military men to a greater extent than had all the previous innovations since the creation of gunpowder.

In the early 1960s military theorists in the western world were re-evaluating the roles and missions of the armies of the future and asking whether the introduction of new weapons had not finally erased the historic distinctions between ground, naval and air forces. In the U.S.S.R. and Communist China, however, military and political leaders continued to view the role of the army as separate and necessary. *See* AIR POWER; AMPHIBIOUS WARFARE; ARTILLERY; ATOMIC ENERGY; CIVIL DEFENSE; ROCKETS AND GUIDED MISSILES; TACTICS; *see* also references under "Army" in the Index volume.

(M. S. WN.; H. M. CE.)

ARMY WORM, the name applied generally to the caterpillars (larvae) of certain kinds of Lepidoptera that sometimes migrate to new feeding grounds in large armies, destroying corn, small grains, sugar cane, cotton and other crops as they move. The name is applied specifically to the true army worm, *Pseudaletia unipuncta* (*Cirphis unipuncta*) of the moth family Noctuidae, which is found in the U.S. and Canada east of the Rocky mountains.

The moths deposit their greenish-white eggs in rows or clusters on the underside of lower leaves of grasses or small grains. They are particularly attracted to rank-growing grains in lowlands but may deposit eggs in lush grain fields anywhere. The larvae hatch and grow slowly, eating small amounts of leaf tissue and causing little if any damage. During the time small grains begin to head, the larvae enter the last larval stage and suddenly exhibit tremendous appetites. This stage, in which they are most destructive, lasts about ten days, during which time the grain fields may be literally overrun with worms up to 2 in. long. The seemingly smooth-skinned larvae are dark green with longitudinal white stripes on their sides and down the back. During the day they hide under pieces of earth or inside plants, emerging at night to feed. The larvae will attack all grasses, some legumes and almost any other plant if grasses are not available.

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

ARMY WORM CATERPILLAR (CIRPHIS UNIPUNCTA) FEEDING ON LEAF

At the end of their voracious period the larvae leave the scene as quickly as they came, partly owing to natural control by predators, lack of food, etc., and partly owing to pupation. Preparatory to pupating the full-grown larvae burrow a short distance into the soil or creep beneath stones and develop into dark brown pupae about ¾ in. long with a tapered tail and blunt head.

About two weeks after the beginning of pupation pale brown or brownish-gray moths emerge having a wingspread of 1½ in. The moths are not immediately ready for egg production and are strongly attracted to molasses baits and other sweets. Three generations and part of a fourth are usually developed in the mid-western U.S. Not all generations are equally destructive.

Several beetles, wasps and flies parasitize the army worm and in most years keep it under control. But when these natural controls are removed, the army worm may destroy farm crops in an area of several hundred square miles. Control measures that man has used against the army worm include sprays and dusts of a mixture of DDT and toxaphene, poison bran, furrows with loose dirt sides (trenching), kerosene and dragging logs.

In some localities the name army worm is used to indicate the

army cutworm (*Chorizagrotis auxiliaris*) or certain species of *Laphygma*, including the fall army worm, beet army worm and nutgrass army worm.

ARNAUD, HENRI (1641–1721), Savoyard pastor who led the Waldensian or Vaudois exiles on the *glorieuse rentrée*, their historic journey back from Switzerland to their Piedmontese valleys, was born at Embrun in Dauphiné of parents from Luserna in Piedmont, whither the family returned about 1650. After studying theology in Switzerland (Basel 1662, 1668; Geneva 1666), Arnaud returned to Piedmont and established himself as pastor at Torre Pellice (1685), where he led the resistance of the Waldensians to the persecution inaugurated by Victor Amadeus II of Savoy. Eventually, however, he joined the Waldensian exiles in Switzerland. With help from William III of Orange, Arnaud did much to rally these exiles. In 1689, encouraged by William's accession to the English throne, Arnaud decided to lead them back to Piedmont (they had already tried twice to return, in 1687 and 1688). Starting from Nyon with about 1,000 followers on Aug. 17, 1689, he made an arduous journey over the Alpine passes, reaching the valley of San Martino ten days later. From Oct. 1689 to May 1690, he was besieged in the citadel of Balsille, from which he escaped under cover of fog to the valley of Angrogna. In June 1690, however, when Savoy entered the War of the Grand Alliance against France, Victor Amadeus made peace with the Waldenses, who then took up arms on his side. When Victor Amadeus made peace with France in 1696, persecution began again. About 3,000 Waldenses went into exile in July 1698, under threat of death. Arnaud then went to Germany, where he founded a Waldensian settlement at Schönenberg in Württemberg (introducing the cultivation of lucerne and mulberries). Between 1704 and 1706, during the War of the Spanish Succession, the Waldenses were again tolerated by Savoy in return for support against France, and Arnaud returned to Piedmont to be pastor of San Giovanni di Luserna. He visited England to obtain funds for his co-religionists in 1707. After this he returned to Schönenberg, where he died on Sept. 8, 1721.

As well as general histories of the Waldenses (*q.v.*) in the 17th century, *see* J. Jalla, *Henri Arnaud* (1926); D. Jahier, *Henri Arnaud* (1926). (L. Ma.)

ARNAULD, the name of a French family of the lesser nobility, which came from Auvergne to Paris in the 16th century and is chiefly remembered for its close connection with Jansenism and with Port Royal (*q.v.*) in the 17th century.

Antoine Arnauld (1560–1619) was born in Paris, the son of Antoine Arnauld, seigneur de La Mothe. Well known as an eloquent lawyer, he pleaded for the University of Paris against the Jesuits in 1594 and presented his case so forcefully that his speech on this occasion has been called "the original sin of the Arnaulds," as if it were the first cause of the Jesuits' animosity against the family. He married Catherine Marion de Druy and he had 20 children, 10 of whom died young. All except one of the surviving children were in some way connected with Port Royal. In 1629 Arnauld's widow herself became a nun at Port Royal de Paris, where she died in 1641.

The most notable of Arnauld's surviving children was Jacqueline Marie Angélique Arnauld (1591–1661), known as Mère Angélique. She took the veil at Maubuisson in 1600 and was made abbess of Port Royal in 1602, when she was not yet 12. She had become a nun only by the decision of her parents and had had no vocation for a monastic life, but in 1608 she was converted by a visiting Capuchin friar's sermon. She then undertook to reform her monastery. After an arduous struggle, even against her own family, she succeeded, and Port Royal became a house of deep spirituality. Mère Angélique was later engaged in the reform of several other convents, especially Maubuisson. From 1618 to 1622 she was under the guidance of St. Francis (*q.v.*) of Sales. It was she who in 1625–26 transferred the community of Port Royal to Paris. In 1635 she came under the influence of the abbé de Saint-Cyran (*see* DuVergier de Hauranne, Jean). She was a strong personality, a woman of deep faith and piety, less inclined to mysticism than to asceticism, with a will of iron and inflexibly austere in the conduct that she imposed on herself and on others, but kindhearted. In the Jansenist group her influence was all-powerful. Her last years were darkened by the troubles in which Port Royal became involved because of its Jansenism, but she bore the troubles with constant fortitude and magnificent spirit. "What are men?" she would often say, "Only flies!" On her deathbed she wrote a touching letter to the queen mother protesting against the constraint that was inflicted on her community. She died on Aug. 6, 1661. Some of her writings, including her *Lettres*, were published in the 18th century (1742–44).

The five sisters of Mère Angélique were all eventually nuns at Port Royal, and all attained celebrity. The most remarkable of them was Jeanne Arnauld (1593–1671), known as Mère Agnès, who entered the cloister very young. From 1630 to 1636 she governed the Cistercian monastery of Tard, near Dijon. She then came back to Port Royal, where she was twice elected abbess (1636 and 1658). In Aug. 1664, during the great persecution of the Jansenists of 1661–69, she was taken away from her community and detained in the Visitandines' convent of Chaillot, persistently refusing to subscribe to the formulary condemning Jansen. In July 1665 she was transferred to Port Royal des Champs with the other recalcitrant nuns. After the so-called "peace of the church" or "peace of Clement IX" (1669), which suspended the persecution, she lived quietly for the rest of her life and was held in general veneration. She was sweet-tempered, calm and mystical, unlike Mère Angélique but no less saintly, and was a spiritual writer of distinction, though few of her works were published. One of them, the *Chapelet secret du Saint-Sacrement*, gave rise to an involved controversy in 1633, being condemned by some doctors of the Sorbonne, but defended by Saint-Cyran. She was the principal author of the *Constitutions* of Port Royal, printed in 1665. There is a collected edition of her *Lettres* by Rachel Gillet, with a preface by Prosper Faugère (1858).

Another sister of Mère Angélique, Catherine Arnauld (1590–1651), was married in 1605 to Isaac Le Maître, a king's counselor, but the marriage was an unhappy one and they parted in 1615. After her husband's death, Catherine became a novice at Port Royal de Paris in 1640 and took her vows in 1644. She had five sons who, with one exception, retired to Port Royal des Champs as *solitaires* (*see* below). Two of these sons, though they did not bear the name Arnauld, must be mentioned here.

Catherine Arnauld Le Maître's eldest son was Antoine Le Maître (1608–1658). As a young man he seemed likely to distinguish himself as a lawyer, but disappointment in love and the sudden death of a relative caused him, in 1637, to put himself under the direction of Saint-Cyran and to retire from worldly society. In 1638, with two of his brothers and some other like-minded persons, he established himself at Port Royal des Champs, where he was to spend his days in prayer, study and work in the fields. This was the beginning of the group of *solitaires* ("hermits") of Port Royal, men who lived within the precincts of the convent and devoted themselves entirely to its material and spiritual welfare. At the beginning of 1656, when the attack on the Jansenists was gaining strength, Antoine Le Maître went into hiding in Paris with Blaise Pascal (*q.v.*), the great Antoine Arnauld (*see* below) and Pierre Nicole (*q.v.*). He then collaborated in the composition of Pascal's *Lettres provinciales* and helped in controversy by writing his *Lettre d'un avocat au parlement* (June 1657). Exhausted by hard work and ascetic practices, he finally returned to Port Royal des Champs where he died. He was an excellent translator of Latin and Greek works, particularly of patristic texts.

The fourth son of Catherine Arnauld Le Maître was Louis Isaac Le Maître de Sacy (1613–1684). Showing a religious disposition early in life, Sacy studied the Bible and patristical theology under Saint-Cyran's guidance and acquired a deep knowledge of these subjects. In 1649 he was ordained priest in order to become a confessor to the nuns and *solitaires* of Port Royal. By 1655 he was in contact with Pascal, and the famous *Entretien avec M. de Sacy* is made up of fragments of their correspondence. In 1661 the persecution against the Jansenists forced Sacy into hiding, but in

1666 he was arrested and imprisoned in the Bastille. Released in 1668, he returned to Port Royal des Champs for some years, during which he came to be held in high esteem by the Jansenists as a spiritual director. The renewal of persecution against Port Royal obliged him to retire to the château of Pomponne in 1679, where he remained until his death. His *Lettres chrétiennes et spirituelles*, published in 1690, show the intellectual power and profundity with which he examined religious questions. Sacy moreover must be considered as the principal author of the translation of the New Testament known as the *Nouveau Testament de Mons* (1667; so called because the first edition bore the imprint of Mons though it was really an Elzevir publication), to which the Great Arnauld, Nicole and others also contributed. This version, made from the original Greek text, marked a notable advance in biblical studies, though it was unfavourably criticized by the learned Richard Simon. It was followed by Sacy's translation of the whole Bible from the Latin text (with the notes and commentaries of St. Augustine and other Fathers of the Church), which appeared between 1672 and 1693. Among his numerous other translations the best known is that of the *Imitation of Christ* (1662).

The eldest of Mère Angélique's brothers was ROBERT ARNAULD D'ANDILLY (1589-1674). Employed in the government service, he seemed destined for a brilliant career in it. Though the influence of Saint-Cyran, whose acquaintance he made in 1620, soon led him to consider retiring from the court and worldly society, he decided at first to remain there so as to exercise a form of spiritual influence on his environment. About 1646, however, he withdrew to Port Royal des Champs, having published previously a book of *Lettres* (1645) in justification of his intention. His connection with the French court made him important in Jansenist affairs, and he was also admired for the purity of his literary style. He wrote a number of poems, some of which were published as *Oeuvres chrétiennes* in 1642, his "Ode à la Solitude" being especially beautiful. His *Mémoires* (not printed until 1734) contain much valuable information. Apart from these original works, he edited Saint-Cyran's *Lettres chrétiennes et spirituelles* (1645) and published numerous translations from Latin, Greek and Spanish, the most successful of the latter being those of St. Augustine's *Confessions* (1649) and of the works of St. Teresa of Ávila (1670). His versions are skilful and elegant but sometimes stray from the original text. A collected edition of his works was published in 1675. By his marriage with Catherine Lefebvre de la Boderie he had 15 children, 5 of whom died in infancy.

Robert Arnauld d'Andilly's eldest son, ANTOINE ARNAULD D'ANDILLY (1616-1698), left some interesting *Mémoires* (published in 1756). SIMON ARNAULD DE POMPONNE (1618–1699), Robert's third son, was early employed in the diplomatic service and in 1671 was appointed secretary of state and minister of foreign affairs. Dismissed in 1679, he was recalled to the ministry in 1691. Five of Robert's daughters were nuns at Port Royal des Champs, the best known of them being the one whose religious name was ANGÉLIQUE DE SAINT-JEAN (1624–1684). Educated in the convent and profoundly devout, Angélique de Saint-Jean was considered by all as a prodigy of learning; she was, in fact, kind-hearted and intelligent, with a gift for writing. Those who refused to subscribe to the anti-Jansenist formulary were to a large extent inspired by her. In 1664 she was taken from Port Royal and confined in the convent of the Annonciades in Paris, where she suffered much ill treatment. Back at Port Royal in 1665, she wrote an admirable *Relation de captivité* (printed in 1711). Elected abbess in 1679, she remained at Port Royal until her death. Of her numerous spiritual writings, the best are *Conférences* (published in 1760) and *Exercices de piété* (1787).

HENRY ARNAULD (1597–1692) was a brother of Robert Arnauld d'Andilly and Mère Angélique. After a diplomatic career, he became bishop of Angers in 1649 and took an important part in controversy, his sympathy being with the Jansenists.

The last of Robert's and Mère Angélique's brothers, but not the least of the family, was ANTOINE ARNAULD (1612–1694), known as the Great Arnauld. Brilliant at his studies, first in law and then in theology, he received a doctorate at the Sorbonne in 1642. He had for a time been tempted by worldly ambitions but, under Saint-Cyran's influence, abandoned them and devoted himself entirely to the defense of the truth as he saw it. He started by publishing his treatise *De la fréquente communion* (1643), in which he vindicated Saint-Cyran's views on the Eucharist and on penance. The book had great success in some quarters but also provoked a violent reaction, and Arnauld thought it wise to go into hiding. In the following years he applied himself first to defending the *Augustinus* of Jansen and the Augustinian theories on grace. On this subject he wrote one of his best works, the *Apologie pour les Saints Pères* (1650). With his *Théologie morale des Jésuites* (published in 1643), he began his great attack on the Jesuits, in which Pierre Nicole, a young theologian from Chartres, was to be his collaborator. Two of Arnauld's pamphlets, the *Lettre à une personne de condition* (Feb. 1655) and the *Lettre à un duc et pair* (July 1655), in which he affirmed the substantial orthodoxy of Jansen, gave rise to a complicated dispute that led to his being expelled from the Sorbonne (Feb. 1656). It was in defense of Arnauld that Pascal with the help of the whole Port Royal group, launched his *Provinciales*. During the great persecution of 1661–69, Arnauld was a leader of the resistance and wrote numerous pamphlets.

Pope Clement IX's "peace of the church" (1669) brought Arnauld some years of tranquillity, beginning with the gracious reception accorded to him by Louis XIV, and he next turned to writing against the Calvinists and on subjects disputed between Catholics and Protestants, his most important work of this period being *La Perpétuité de la foi catholique touchant l'Eucharistie*, 3 vol. (1669–74). He then won such fame as a theologian that Pope Innocent XI is said to have considered making him a cardinal. In 1679, however, the persecution of the Jansenists broke out again, and Arnauld had to leave France in June and seek refuge in the Netherlands. After staying at Brussels, Mons, Tournai, Ghent and Utrecht, he settled permanently in Brussels (Oct. 1682), where he was to remain in voluntary exile until his death. Some of his friends joined him there, and from 1685 he had with him the celebrated Pasquier Quesnel (*q.v.*), who was to succeed him as the leader of the Jansenist party. Despite the precarious conditions in which he had to work, the amount of Arnauld's writing during his exile was enormous. He not only resumed his attack on the Jesuit casuists in the last six volumes of his *Morale pratique des Jésuites* (1689–94; the first two had appeared in 1669 and 1682), but also intervened in the dispute over the king's rights in the Gallican church (*see* GALLICANISM) and wrote on English affairs in his *Apologie pour les Catholiques* (1681).

Arnauld was moreover distinguished as a philosopher and as a mathematician. For the *Port Royal Logic* (*La Logique, ou l'art de penser*, 1662) on which he and Pascal collaborated, *see* LOGIC, HISTORY OF. His *Éléments de géométrie* (not published till 1667) won Pascal's admiration. He also took a lively interest in the philosophy of Descartes, though he could not accept it without reservation. At first he had been the friend of Nicolas Malebranche (*q.v.*), but the latter's *Traité de la nature et de la grâce* (1680) seemed to him incompatible with Augustinian principles and began a long and somewhat painful controversy between them which continued unabated until Arnauld's death. His main works in this controversy were the *Traité des vraies et des fausses idées* (1683), in which he refutes Malebranche's theory of "representative ideas" whereby all perception is held to be "in God," and the *Réflexions philosophiques et théologiques* (1685), against Malebranche's theories on grace. Finally, in 1691, Arnauld also had a controversy with Nicole about what Nicole called "general grace," a type of divine grace which, according to Nicole, could be granted to all men, even to non-Christians; but the documents on this question were kept secret and did not appear until 1715. *See* also JANSENISM.

ARNDT, ERNST MORITZ (1769–1860), German poet and

patriot who expressed the national awakening in his country in the Napoleonic era. He was born on Dec. 26, 1769, at Schoritz in the island of Rügen which then belonged to Sweden. He was educated at Stralsund, Greifswald and Jena, and qualified for the Lutheran ministry. At the age of 28 he rejected his clerical career and for 18 months traveled through Austria, Hungary, Italy, France and Belgium. On returning to his country the sight of the ruined castles along the banks of the Rhine moved him to bitterness against the French enemy. He described the impressions of this journey in *Reisen durch einen Teil Deutschlands, Ungarns, Italien, und Frankreichs in den Jahren 1798/99*, 6 vol. (1801–03). In 1800 he settled in Greifswald as assistant lecturer in history, and in 1803 appeared his *Germanien und Europa* in which he proclaimed his views on French aggression. Then came one of his most remarkable books *Versuch einer Geschichte der Leibeigenschaft in Pommern und Rügen* (1803), a history of serfdom in Pomerania and Rügen that resulted in its abolition, three years later, by the Swedish king Gustavus IV. In 1806 Arndt, appointed to the chair of history at Greifswald university, published the first part of his *Geist der Zeit* (Eng. trans., *Spirit of the Times*, 1808) in which he called on his countrymen to shake off the French yoke. To escape the vengeance of Napoleon he was obliged to take refuge in Sweden, but he continued to communicate his patriotic ideals to his countrymen in pamphlets, poems and songs. The heroic death of the Prussian officer Ferdinand von Schill at the battle of Stralsund in 1809 compelled him to return to Germany. He was closely associated with the field marshals Blücher and Gneisenau and also with the German statesman Baron von Stein. In 1812 Stein summoned him to St. Petersburg to assist in the organization of the final struggle against France. Meanwhile Arndt produced further patriotic pamphlets and songs. When, after the peace, the University of Bonn was founded in 1818, Arndt was appointed to the chair of modern history. In this year appeared the fourth part of his *Geist der Zeit*, in which he criticized the reactionary policy of the German powers. The boldness of his demands for reform offended the Prussian government, and in the summer of 1819 he was arrested. He was soon set free but not allowed to teach. In 1840 he was reinstated and in 1841 was appointed rector of the university. After the revolutionary outbreak of 1848 he took his seat as one of the deputies to the national assembly at Frankfurt am Main. He took part in the deputation that offered the imperial crown to Frederick William IV, but, indignant at the king's refusal to accept it, he retired, with the majority of Heinrich von Gagern's adherents, from public life. He died at Bonn on Jan. 29, 1860.

Not all of Arndt's lyrical poems were inspired by political ideas. Nor was he a merely chauvinistic figure. It has been suggested that Arndt was more liberal-minded than was once thought, having been influenced by the ideals of the French Revolution, the betrayal of which he resented. Many of the *Gedichte* (1804–18; complete ed. 1860) are religious poems of great beauty. Among his other works are his autobiography, *Erinnerungen aus dem äusseren Leben* (1840), the most valuable source of information for Arndt's life, and *Meine Wanderungen und Wandelungen mit dem Reichsfreiherrn Heinrich Karl vom Stein* (1858). Of many editions of Arndt's works, *see* that by H. Meisner and R. Geerds, 16 vol. (1908).

Pundt, *Arndt and the Nationalist Awakening in Germany* (1935).

ARNDT, JOHANN (1555–1621), German Lutheran theologian and mystic, was born at Ballenstädt, in Anhalt, on Dec. 27, 1555, and studied in several universities. At Wittenberg the crypto-Calvinist controversy was then at its height, and he took the side of Melanchthon and the crypto-Calvinists. He became pastor of Badeborn in 1583, but in 1590 he was deposed for refusing to remove the pictures from his church and discontinue the use of exorcism in baptism. He found asylum in Quedlinburg (1590), and afterward was transferred to St. Martin's church at Brunswick (1599). Arndt died on May 11, 1621.

Arndt's fame rests on his writings. These were mainly of a mystical and devotional kind, and were inspired by St. Bernard, J. Tauler and Thomas à Kempis. His principal work, *Vier Bücher vom wahren Christentum* (1606), translated into most European languages, served as the foundation of many books of devotion, both Roman Catholic and Protestant. His *Paradiesgärtlein aller christlichen Tugenden* (1612) also is well known. Arndt has always been held in high repute by the German Pietists.

A collected edition of Arndt's works in three volumes was published in Leipzig in 1734–36, under the editorship of J. J. Rambach.

See C. Oehmann, *Essai sur la vie et la doctrine de J. Arndt* (1861); W. Koepp, *Johann Arndt*, with bibliography (1912).

ARNE, THOMAS AUGUSTINE (1710–1778), English composer, chiefly of dramatic music and songs for London's theatres and pleasure gardens. Born in London, according to tradition, on March 12, 1710, he was the son of an upholsterer in King street, Covent Garden. Educated at Eton, he was intended for the law but by secretly practising he acquired such mastery of the violin and keyboard instruments that his father withdrew all objections to a musical career. Except for some lessons from Michael Festing, later leader of the Italian Opera orchestra, Arne was self-taught, and it was at the Opera (which he attended in a footman's livery to obtain free admission) that his musical taste was largely formed. He taught both his sister, later famous as the actress Mrs. Cibber, and his young brother to sing, and they appeared in his first stage work, *Rosamond* (1733). This opera, based on Joseph Addison's libretto of 1707, was set "after the Italian manner" and its bravura air "Rise, Glory, Rise" was sung at the theatres and pleasure gardens for the next 40 years.

Arne was soon engaged to write musical after-pieces and incidental music for Drury Lane theatre, and with *Comus* (1738), John Dalton's adaptation of Milton's masque, he became established as the leading English lyric composer. Dr. Burney wrote, "He introduced a light, airy original and pleasing melody, wholly different from that of Purcell and Handel," and this individual melodic style can also be heard in *Alfred* (notable for "Rule, Britannia") and *The Judgment of Paris*, both produced at the prince of Wales's residence at Cliveden in 1740. Arne's settings of Shakespeare's songs, written for revivals of *As You Like It, Twelfth Night* and *The Merchant of Venice* in 1740–41 provide the culmination of this early melodious style. Meanwhile in 1737 Arne had married Cecilia Young, who had already sung in Handel's operas and oratorios, and in 1742–44 the couple paid a highly successful visit to Dublin.

On his return Arne was engaged as composer to Drury Lane theatre and Vauxhall gardens, and during the next decade published song collections under such titles as *Lyric Harmony, Vocal Melody*, and *The Agreeable Musical Choice* which, as Burney wrote, were "the standard of all perfection at our theatres and public gardens." In 1755–56 came a second visit to Dublin, at which time Arne became estranged from his wife, who remained in Ireland. The following year he published his *Lessons for the Harpsichord* and his *Sonatas for two Violins and a Bass.* In 1759 he was made doctor in music at Oxford, and two years later his oratorio *Judith* was produced, followed by the opera *Artaxerxes* (1762), for which he provided his own English text, based on Metastasio. *Artaxerxes* held the stage until the early 19th century, but Arne's *opera buffa, The Guardian Outwitted* (1764), was a failure, largely because he was the author of the libretto, and his *Olimpiade* (1765), produced at the Italian Opera, survived only two performances.

In the final decade of his life Arne gave annual concerts of catches and glees, together with musical pieces designed to display the talents of his singing pupils. He set Garrick's ode for the Stratford Shakespeare jubilee of 1769 and composed music for *The Fairy Prince* (1771) and Mason's *Elfrida* (1772) and *Caractacus* (1776). He died, March 5, 1778, after a reconciliation with his wife, and was buried at St. Paul's, Covent Garden, where his birth had been registered.

Arne's early melodic style was natural and elegant, owing something to Scots, Irish and Italian sources. His later music became more Italianate and ornamented, though in his final years there emerged an *opera buffa* style that anticipates Sullivan. As the composer of such melodies as "Rule, Britannia," "Blow, Blow,

Thou Winter Wind" and "Where the Bee Sucks" Arne, like Purcell, added substantially to the English heritage of song.

See the article in Grove's *Dictionary of Music and Musicians*, 5th ed. (1954) which contains the most comprehensive list of Arne's works, especially for the theatre, although it, and other accounts of Arne, should not be relied on entirely. (JU. H.)

ARNETH, ALFRED VON (1819–1897), Austrian historian, important chiefly for his work in evaluating and publishing sources for Austrian history found in the Vienna state archives, was born in Vienna on July 10, 1819. His father, Joseph von Arneth (1791–1863), was custodian of coins and antiquities at the Vienna museum and author of numerous archaeological and numismatic works. His mother Antonie Adamberger (1790–1867), a notable actress at the Vienna Hofburg theatre, had been earlier betrothed to Karl Theodor Körner. Arneth studied law and history at Kremsmünster and Vienna and was appointed by Metternich to the state archives, of which he became keeper in 1868. He supported the opening of the archives to scholars. In 1879 he became president of the Kaiserliche Akademie der Wissenschaften and in 1896 succeeded Heinrich von Sybel as chairman of the historical commission at Munich. Arneth also had a political career, being a member of the Frankfurt assembly in 1848, of the Lower Austria *Landtag* from 1861 and of the *Herrenhaus* from 1869. He supported the liberal constitutional party. He died on July 30, 1897, in Vienna. His chief publications were devoted to the 18th century and derived their value from the special facilities open to him. They include lives of the field marshal Guido von Starhemberg (1853), of Prince Eugène of Savoy (1858–59) and of Maria Theresa (1863–79), and numerous collections of correspondence—between Maria Theresa and Marie Antoinette, Maria Theresa and Joseph II, Joseph II and Leopold and Joseph II and Catherine of Russia. He also published his early reminiscences *Aus meinem Leben* in two volumes (1893).

ARNHEM, the capital of Gelderland province of the Netherlands, lies on the right bank of the Lower Rhine 39 mi. by road east-southeast of Utrecht. Pop. (1960) 120,091. The old town with the business and administrative centres is surrounded by a semicircular boulevard on the site of the former ramparts. The newer residential and industrial areas are separated by traffic arteries and parks. Sonsbeek park, to the north, is laid out in early 19th-century Romantic style. In the old town the 14th-century Roman Catholic church of St. Walburgis is to the southeast and nearby is the Protestant church of St. Eusebius (15th century) on the Grote Markt where the 16th-century town hall and modern provincial government house (Huis der Provincie) are situated. The latter is near the site of the old Prinsenhof, the residence of the dukes and later the stadholders of Gelderland. Outside the old town to the west is the municipal museum and art gallery while 10 mi. N. is the Kröller-Muller state art gallery with modern works and a large collection of Van Gogh's paintings. There is also an open-air museum and zoo. Oosterbeek is the site of the cemetery where British air-borne troops who died in the battle of Arnhem are buried. Arnhem is a tourist centre; it has a theatrical company and a symphony orchestra. Main railways run to Amsterdam, Rotterdam, The Hague and into Germany. There are arterial roads to the west and to Germany. Rayon fibres, electrical equipment, ships, metal work and clothing are manufactured. (J. A. L.)

It was first mentioned in 893. In 1233 Otto II, count of Gelder, lived there, conferring municipal rights on the town and fortifying it. Later it entered the Hanseatic league. Charles the Bold of Burgundy captured it in 1473 and Philip, son of Maximilian I, gave it coining rights in 1505. In 1514 Charles of Egmont took it from the Spaniards; in 1543 Charles V captured it and made it the seat of the council of Gelderland. It came under the states general in 1585 and the following year Sir Philip Sidney died in the town after being fatally wounded at the battle of Zutphen. The French took it in 1672, but left it dismantled two years later. It was refortified in the 18th century. In 1795 it was again stormed by the French and taken by the Prussians in 1813. In World War II it was captured by the Germans in May 1940. On Sept. 17, 1944, British and Polish air-borne troops were dropped there in an attempt to seize the Rhine bridges, but after a heroic resistance they had to withdraw to the south eight days later. Arnhem was not liberated until April 1945. For an account of the Allied air-borne landing *see* WORLD WAR II: *Allied Reconquest of Western Europe*.

ARNICA, a genus of plants belonging to the family Compositae and containing about 50 species, most of which occur in northwestern America. The most important species of the genus, however, is *Arnica montana*, a perennial herb of the mountains and uplands in northern and central Europe. The rootstock of *A. montana* is tough, slender, of a dark brown colour and an inch or two in length. It gives off numerous simple roots from its underside, and shows on its upper side the remains of rosettes of leaves. It yields an essential oil in small quantity and a resinous matter called arnicin, a yellow crystalline substance with an acrid taste. The tincture prepared from it was once commonly used in the treatment of bruises and sprains.

In North America arnicas are most numerous in the Rocky mountain region from Colorado northward, but there are also many in the Sierra Nevada and Cascade ranges. Conspicuous species may be observed in Rocky Mountain, Glacier, Yosemite, Mount Rainier and other national parks of the western United States and Canada. Several species occur in the northeastern United States and adjacent Canada, mostly on the higher mountains.

Typical of the various far northern species is *A. angustifolia*, with very narrow leaves, occurring in arctic Asia and America. The heads of flowers are 2 to 2½ in. across, orange-yellow in colour and borne on the summit of the stem or branches; the outer ray flowers are an inch in length. The fruit is brown and hairy, and crowned by a tuft of stiffish hairs. The plant was introduced into England in the 18th century.

ARNICHES, CARLOS (1866–1943), Spanish dramatist, born at Alicante on Oct. 11, 1866, created a special version of the *género chico* or "little genre," the traditional type of one-act play that has been a feature of Spanish drama since the *entremeses* ("farces") of Cervantes and the *pasos* ("interludes") of Lope de Rueda in the 16th century. Arniches based his plays upon direct observation of the customs and speech of the people of Madrid. His most popular *sainetes* ("one-act plays") and *zarzuelas* ("musical comedies"), such as *El puñao de rosas* (1902), *El amigo Melquiades* and *Don Quintín el Amargao* (both 1924), became classics of Spanish literature and were set to music by popular composers. He died in Madrid on April 16, 1943. (W. F. SE.)

ARNIM, ACHIM (KARL JOACHIM FRIEDRICH LUDWIG) **VON** (1781–1831), made his mark in German literature as a collector and editor of folk songs and as a writer of stories. He was born in Berlin on Jan. 26, 1781, a descendant of an ancient noble family. In his student years he formed a close friendship with Clemens Brentano (*q.v.*), whose sister he married in 1811 (*see* ARNIM, BETTINA VON). While they were studying at Heidelberg, the two friends jointly published a remarkable collection of folk poetry, *Des Knaben Wunderhorn*. (The title derives from the opening poem, which tells of a youth who brings the empress a magic horn.) The first volume (published in the autumn of 1805, dated 1806) was dedicated to Goethe, who reviewed it appreciatively. Though it was criticized for lacking philological accuracy, this collection (completed in 1808) remains an outstanding achievement of German Romanticism. It succeeded J. G. Herder's equally famous collection of *Volkslieder* (1778–79); but whereas Herder's work includes folk songs of many different countries, Arnim's and Brentano's is emphatically German. In the troubled days of the Napoleonic wars, Arnim sought to restore to his fellow countrymen a sense of their national heritage.

Arnim's numerous plays, poems and novels are deservedly forgotten; but a few of his short stories (*Isabella von Ägypten, Der tolle Invalide, Fürst Ganzgott und Sänger Halbgott*) as well as the fragment *Die Kronenwächter*—all of them strangely compounded of realism and fantasy—are notable contributions to German prose fiction.

Arnim died at his country house of Wiepersdorf, Brandenburg, on Jan. 21, 1831.

Kluckhohn, article on Arnim in *Neue Deutsche Biographie*, vol. 1 (1953). (W. Wi.)

ARNIM, BETTINA (Elisabeth Katharina Ludovica Magdalena) **VON** (1785–1859), was born at Frankfurt am Main on April 4, 1785. She is one of the outstanding women writers in modern German literature, memorable not only for her books but for the personality which they reflect; all her writings, whatever their ostensible themes, are essentially self-portraits.

Gifted women played a prominent role in the German Romantic movement, and Bettina was a Romantic *par excellence*. She was unconventional to the point of eccentricity; wayward, yet a loyal wife (she married Achim von Arnim in 1811) and a devoted mother to her seven children; susceptible and passionate, but jealous of her personal freedom; capable of enthusiastic devotion, yet absorbed in a cult of her own personality which verged on narcissism. These paradoxes in her nature she projected into her books. Her three best-known works purport to be records of her correspondence with Goethe (*Goethes Briefwechsel mit einem Kinde*, 1835—the "child," be it noted, was a young woman of 22), with her friend Karoline von Günderode (*Die Günderode*, 1840) and with her brother Clemens Brentano (*Clemens Brentanos Frühlingskranz*, 1844); but the original letters have been rearranged and retouched, the result being a peculiar blend of documentation and fiction, written in a brilliantly vivid, uninhibited style. Her mother, Maximiliane Laroche, had been on terms of affectionate friendship with Goethe both before and after her marriage to Peter Brentano, an Italian merchant settled at Frankfurt. Maximiliane's connection with Goethe ended abruptly because it aroused her husband's jealousy; 35 years later, however, her daughter took her place. Bettina idolized Goethe (who was 57 when she first met him); she had frequently visited Goethe's mother in Frankfurt and made a point of recording the old lady's tales of the poet's childhood. (Goethe later used her notes when he was writing his autobiography, *Dichtung und Wahrheit*.) In her extravagant way, Bettina pursued Goethe with her attentions, until in 1811 a public quarrel between her and Goethe's wife Christiane caused Goethe to disown her.

She took an active interest in politics, sympathizing with the underprivileged and pleading for victims of political recrimination such as the poet J. G. Kinkel and the brothers Grimm (*q.v.*). She stated her views in two books, written for the special benefit of the king of Prussia, Frederick William IV (*Dies Buch gehört dem König*, 1843; *Gespräche mit Dämonen*, 1852).

Bettina was also a gifted sculptor and musician. Her poetic sensibility is seen in her appreciation of Hölderlin (*q.v.*), whose genius she divined long before it was generally recognized. In the diversity of her talents and interests, she exhibits that universality which Friedrich Schlegel regarded as the hallmark of the Romantic spirit. She died in Berlin on Jan. 20, 1859.

ARNIM, HANS GEORG VON (1581–1641), German soldier and statesman who served different princes according to his personal attitude to contemporary politics, was born of an old noble family at Boitzenburg in Brandenburg. He started his military career in the Swedish service (1613) and fought in Gustavus Adolphus' war against Russia, but quarreled with the king and entered the Polish army in 1621 to fight the Turks. Joining the imperial army under Wallenstein in 1626 and soon made field marshal, he distinguished himself in the campaigns in Silesia, Mecklenburg and Pomerania but failed to take Stralsund in 1628. Sent to Poland in 1629 he defeated Gustavus Adolphus at Sztum. As a strict Lutheran he resigned his commission in protest against the Edict of Restitution and thenceforward worked for the creation of a "third party," under the elector of Saxony, to hold the balance between the imperial court and the encroachment of Sweden, France and Spain. As generalissimo of the Saxon army he fought in the first battle of Breitenfeld and in Nov. 1631 took Prague, but he was ejected from Bohemia by Wallenstein. An opponent of Swedish policy, he approached Wallenstein with a plan for a general pacification which largely coincided with Wallenstein's own ideas, but Wallenstein's assassination in 1634 put an end to these schemes. Leaving the Saxon service in protest against the peace of Prague between the emperor and Saxony (1635), he refused a French commission. Arrested on Swedish orders in 1637 and taken to Stockholm, he escaped to Hamburg in 1638 and was reinstated as imperial and Saxon lieutenant-general. Arnim was occupied with military preparations against France and Sweden when he died suddenly at Dresden on April 28 (new style; 18, old style), 1641.

ARNIM, HARRY (KARL KURT EDUARD), Graf von (1824–1881), Prussian diplomat whose opposition to Bismarck was so indiscreetly expressed that he was accused of treason, was born at Moitzelfitz in Pomerania on Oct. 3, 1824. After studying law, he entered the diplomatic service in 1850, serving in Rome (1853–55) and in Lisbon (1862). He was appointed Prussian envoy to the Holy See in 1864. Before the Vatican council of 1869 he made proposals intended to prevent a declaration of papal infallibility, which, he foresaw, would create serious political difficulties.

Arnim took part in the negotiations to end the Franco-German War and was appointed Prussian envoy to France on Aug. 23, 1871, becoming ambassador on Jan. 9, 1872. In June he arranged the war reparations settlement, but differences soon arose between him and Bismarck. Arnim, who considered that Bismarck's backing of the republican regime in France would encourage opponents of the monarchy in Germany, wished to support the French monarchists, and his intrigues contributed to the fall of A. Thiers (*q.v.*) in May 1873. Arnim's favour at court and his support of the conservative groups among the nobility led Bismarck to suspect that he was planning to supplant him. Then, in 1874 a Vienna newspaper published correspondence on the Vatican council, including confidential dispatches of Arnim's, with a view to showing that he had exhibited greater foresight than Bismarck. It was then found that papers were missing from the Paris embassy. Arnim lost the emperor's favour and, as he refused to return some of the missing documents, Bismarck had him temporarily superannuated and then, on Oct. 4, 1874, arrested. Condemned to three months' imprisonment, Arnim appealed, but the supreme court increased the sentence to nine months. Arnim left Germany and, in 1876, anonymously published *Pro nihilo*, a pamphlet attributing the attack on him to Bismarck's jealousy. Convicted of treason, of insulting the emperor and of libeling Bismarck, he was sentenced *in absentia* to five years' penal servitude.

In Austria, Arnim published two more pamphlets on Prussia's ecclesiastical policy, *Der Nuntius kommt!* (1878) and *Quid faciamus nos?* (1879). His repeated demands for a new trial had just been granted when he died at Nice, in France, on May 19, 1881.

As the legal grounds for the prosecution of Arnim had been rather doubtful, Bismarck, in 1876, carried an amendment to the criminal code, the so-called *Arnim Paragraph*, making the unauthorized disclosure of official documents a criminal offense.

See *Der Arnim'sche Prozess. Stenographische Berichte* (1874); F. Hartung, "Bismarck und Graf Harry Arnim," *Historische Zeitschrift*, vol. 171 (1951).

ARNO (anc. Arnus), the principal river of Tuscany, is second only to the Tiber in importance in central Italy. Its course is 150 mi. long and its drainage basin covers 3,184 sq.mi. The Arno rises on the slopes of Mt. Falterona (5,426 ft.) east-northeast of Florence, and in its upper course traverses the former lake basin called Casentino. Near Arezzo it turns west, flows through a second ancient lake basin, and after the narrow gorge at Incisa enters the third basin, that of Florence. After traversing the

Florence section of its valley, the river enters a last gorge at Golfolina and below it begins its lower course, past Empoli and Pisa, to the Ligurian sea. In the lower section it receives the waters of the rivers Pesa, Elsa and Era. The valley of the Arno was substantially modified by man: in the upper course, the Val di Chiana now drains to the Tiber; flood-control works, some designed by Leonardo da Vinci, control the middle section, though sudden flood in 1966 inundated Florence; while the ancient delta is now reclaimed and the Arno reaches the sea through a single mouth. In its lower course the volume of the river averages 140 sq.yd. per second, with variations from a maximum of 2,600 to a minimum of 2.2; navigation on the river is negligible. Arezzo, Florence and Pisa are the principal cities along the Arno. (G. Kh.)

ARNOBIUS (sometimes called Afer or the Elder), a brilliant Christian apologist, was born a pagan but, as he says himself, had by A.D. 300 become a Christian. Jerome adds other details: Arnobius taught rhetoric at Sicca Veneria in proconsular Africa during the reign of Diocletian, numbering Lactantius among his pupils. Induced by dreams to embrace the newer faith, he met with suspicion because of his former antipathy to Christianity and therefore composed as a pledge of his sincerity the seven "most splendid books" *Against the Pagans* (*Adversus nationes*) and thus received baptism. Hasty readers have done Arnobius grave injustice by too easily viewing the work as the product of a recent convert, not yet perfectly instructed. That he does not, like other apologists, abundantly cite Scripture, implies not his ignorance of it, but that he viewed it as unnecessary to his purpose, which was to defend Christianity by demonstrating to the pagans their own ridiculous inconsistencies. The work is thus a mine of great richness for knowledge of contemporary pagan cults. A general defense of Christianity from pagan calumnies is followed by sustained attacks in turn upon neo-Platonism, anthropomorphism and other weaknesses including myths, and specifically two important myths described in detail, as well as upon pagan temples, images and ceremonials. What appears in earlier printed editions as an eighth book is really the *Octavius* of Minucius Felix, preserved in the same unique manuscript. While the rhetorical style is characteristic of the period, the invective is always brilliant with frequent flashes of humour worthy of a great satirist.

Bibliography.—Latin texts were edited by A. Reifferscheid, *Corpus* (1875) and C. Marchesi, *Corpus Paravianum*, 2nd ed. (1953); for a translation, full introduction (with bibliographies) and commentary, see George E. McCracken, *Arnobius of Sicca: the Case Against the Pagans*, Ancient Christian Writers, 2 vol. (1949). (G. E. McC.)

ARNOBIUS (called the Younger) (fl. *c.* 460), Christian priest or bishop in Gaul, was the author of a mystical and allegorical commentary on the Psalms, first published by Erasmus in 1522, and by him attributed to the elder Arnobius (*q.v.*). He also attacked St. Augustine's doctrine of grace and was author of some notes on the Gospels and of an anti-Monophysite treatise. The opinions of Arnobius, as appears from the commentary, are semi-Pelagian.

ARNOLD of Brescia (Arnaldo da Brescia) (d. 1155), priest and monk, was an outspoken critic of the wealth and corruption of the clergy and became a vigorous opponent of the temporal power of the pope. Born in or near Brescia toward the close of the 11th century, he studied letters and theology, but it is doubtful whether he was a pupil of Peter Abelard, as stated by Otto of Freising (*Gesta Friderici*, ii, 28). Arnold took part in a popular revolt against the government of Bishop Manfred at Brescia in 1137, and was condemned as a schismatic by Pope Innocent II in 1139. Banished from Italy he went to France, where he became a supporter of Abelard, whose errors in Trinitarian doctrine St. Bernard charged him with sharing. At the Council of Sens (1140) both were condemned. While Abelard submitted to authority, Arnold defiantly continued teaching in Paris until he was exiled by King Louis VII at the importunate insistence of St. Bernard (1141). From Paris Arnold fled first to Zurich, then to Passau. There he was protected by Cardinal Guido, legate to Bohemia and Moravia, through whose mediation he was reconciled with Pope Eugenius III at Viterbo (Sept. 1145).

Two years earlier a revolt had broken out in Rome. Pope Innocent II and the cardinals had been expelled, the ancient senate revived and a republic proclaimed by the Roman aristocracy. Pope Eugenius unwisely now sent Arnold to Rome on a penitential pilgrimage. Before long he made common cause with the insurgents and resumed his preaching against pope and cardinals, denouncing Eugenius as "a man of blood" and the papal *curia* as "a house of merchandise and a den of thieves." He was excommunicated in July 1148, and from this point his career was bound up with the fortunes of the Roman republic. Agitation for ecclesiastical reform reinforced and permeated the revolt against the pope as temporal ruler. Arnold speedily acquired a moral and political ascendancy over the Romans through his oratory and gift of leadership. The able and energetic Pope Adrian IV (*see* Adrian) placed Rome under interdict in 1155, and called upon the citizens to surrender Arnold. The senate tamely submitted; the republic collapsed, and the papal government was restored. Arnold, who had fled the city, was captured by the forces of Frederick I (*q.v.*), then visiting Rome for his imperial coronation. Arnold was tried by an ecclesiastical tribunal, condemned for heresy and handed over to the emperor for execution. He was hanged, either at Civita Castellana or at Monte Rotondo, in about June 1155, his body being then burned and the ashes cast into the Tiber lest they should be treasured as relics.

Arnold's character was austere and his mode of life ascetic. St. Bernard, his implacable enemy, described him as "a man who came neither eating nor drinking," and admitted that his morals were above reproach. His teaching was inspired by the gospel, fortified by the example of the early church and more immediately derived from that of the Patarini, a sect that sought to reform the clergy in Lombardy during the 11th century. Essentially an idealist, "he taught things most consonant with the law of Christians, but altogether remote from everyday life" (John of Salisbury, *Historia pontificalis*, xxxi). He left followers, known as Arnoldists, and although the extent of his influence on the heretical sects of the 13th century is problematical, his cardinal tenet of the incompatibility of spiritual power with material possessions was widely held among them. In modern times Arnold has attracted the attention of poets, dramatists and Italian politicians, and his personality has been gravely distorted in the process. He was before all else a religious reformer, constrained by the circumstances of his time to adopt the role of a political revolutionary.

See G. W. Greenaway, *Arnold of Brescia*, with full bibliography (1931). (G. W. Gr.)

ARNOLD, BENEDICT (1741–1801), American officer in the Revolutionary War who deserted to the British, was born in Norwich, Conn., on Jan. 14, 1741. His family had been a distinguished one in Rhode Island. In the fall of 1757 he served with the militia in the French and Indian War, but soon returned home and completed his apprenticeship with a firm of druggists. In 1762 he opened a drug and book store in New Haven. As the store prospered, Arnold bought ships and engaged in trade with Canada and the West Indies.

Late in 1774 he was elected captain of a militia company. When news of the outbreak of hostilities at Lexington arrived in April 1775, Arnold marched his company to Cambridge and immediately proposed the capture of Ft. Ticonderoga and seizure of its cannon. Named a colonel by Massachusetts on May 3, 1775, he was authorized to raise a regiment and proceed with his plan. But he soon found himself forestalled by Ethan Allen (*q.v.*), who had been authorized by Connecticut to undertake the same mission and had already recruited a force. Reluctantly waiving his own claim to command, Arnold joined Allen as a volunteer in the successful attack. He then seized a ship and with a hundred men ran down Lake Champlain and captured St. John's.

When Arnold returned to Cambridge, Washington gave him command of an expedition to Quebec via the Maine wilderness. The march of 700 men was a remarkable feat of woodsmanship and endurance, but Quebec was too strong to be attacked until Arnold was joined by Gen. Richard Montgomery's force from Montreal. The combined assault in a snowstorm on Dec. 31, 1775, failed; Montgomery was killed, and Arnold severely wounded. Congress promoted him to the rank of brigadier general, and he continued to besiege the city until spring when he was forced to retreat to

Montreal and Lake Champlain. Enlarged British forces followed, intent on reaching Albany. Arnold constructed a flotilla on Lake Champlain and inflicted severe losses on a greatly superior enemy fleet near Valcour Island, Oct. 11, 1776. He returned home a hero, but his rash courage and impatient energy had aroused the enmity of several other officers. When in Feb. 1777 congress created five new major generals, Arnold, the ranking brigadier, was passed over in favour of his juniors because of the political necessity of apportionment among the states. Only Washington's personal persuasion kept Arnold from resigning.

Two months later, while he was at New Haven, Danbury was attacked. Arnold took immediate action and drove the British back to their ships. This exploit forced congress to make him a major general but his seniority was not restored, and Arnold felt his honour impugned. He tried to resign but accepted congress' order in July to join Gen. Philip Schuyler above Albany to stem a fresh invasion from Canada under Gen. John Burgoyne (*q.v.*). He marched up the Mohawk valley in August against Col. St. Leger and raised the siege of Ft. Stanwix (Rome, N.Y.). Arnold later commanded the left wing in the first battle of Saratoga (Sept. 19). In the second battle (Oct. 7) he galloped into action, took command of advance battalions, and fought brilliantly and decisively until seriously wounded. For his services he received a new commission restoring him to his proper relative rank.

Since Arnold's wounds had left him crippled, Washington placed him in command of Philadelphia in June 1778. He enjoyed the city's social life, moved among families of Loyalist sympathies, and lived extravagantly. To make money he violated several state and military regulations, arousing the suspicions and finally the denunciations of Pennsylvania's supreme executive council. The charges against Arnold were then referred to congress. Some of the charges were thrown out, but four remained and Arnold asked for a speedy court-martial to clear himself. Meanwhile, on April 8, 1779, four years after the death of his first wife, he married young Margaret (Peggy) Shippen (1760–1804), daughter of a moderate Loyalist. She had been impressed by the society of British officers during the previous winter of occupation and was Loyalist in feeling. Either she suggested that they change sides or readily seconded such a suggestion from Arnold, for early in May he made secret overtures to British headquarters. He was asked to remain on the American side and send information until he obtained an important post or field command that he could betray. Payment was promised, but the British were vague about the amount, to Arnold's irritation. He did forward intelligence from time to time and persisted in asking £10,000 for indemnification plus the rank of major general in the British army for his services. The correspondence lapsed in Oct. 1779.

Arnold's postponed trial finally was held in Dec. 1779, and he was found guilty of two minor offenses and sentenced to a reprimand by Washington. Mild and just as the sentence was, Arnold was furiously aggrieved. He reopened the treasonable correspondence in May 1780, sending news of the proposed invasion of Canada and later revealing that he expected to obtain the command of West Point. Having now an important fort to deliver, he asked £20,000 for betraying it, and half that sum if he failed and fled to the British lines. Maj. John André (*q.v.*) arranged to meet him on Sept. 21 under a misuse of a flag of truce. As the ship that brought André up the Hudson was fired upon and forced to retire, André spent the night within American lines. The next day he was persuaded to don civilian disguise in order to return overland to New York, provided with a pass by Arnold. When notified of André's capture, Arnold managed to escape on the boat that had returned for André, leaving the latter to be hanged as a spy. His wife joined him later in New York.

The sacrifice of André made Arnold odious in New York, but Clinton named him a provincial brigadier general, awarded him £6,000 plus expenses, and authorized him to raise a regiment of American deserters. Only 28 privates responded to his published appeals. He was sent on a raiding expedition to Virginia and captured Richmond, and in Sept. 1781 led a raid on New London, Conn. Upon Cornwallis' surrender, Arnold obtained permission to go to England and sailed on Dec. 15. Naïvely he hoped to succeed Clinton as commander in chief, but the Tory ministry fell; peace was negotiated; and Arnold became a retired colonel on half pay. His wife was given a pension of £500 a year "for her services"; each of his sons was given a military commission and drew pay although too young to serve. Later the younger children were given pensions of £100.

Disappointed at the failure of his plans and embittered by the neglect and scorn he met in England, Arnold spent the years 1787–91 at Saint John, N.B., once more engaging in the West India trade. But he was greatly disliked in Canada and in 1792 returned to London. He failed to get a command in the war with France and fought a duel with an earl who insulted him. Going to the West Indies again to trade, he was captured by the French and escaped but steadily lost money. Inactive at home, ostracized and ailing, he died on June 14, 1801. His faithful wife survived him only three years.

Bibliography.—Willard M. Wallace, *Traitorous Hero* (1954); Carl Van Doren, *Secret History of the American Revolution* (1941) contains the André-Arnold correspondence; James T. Flexner, *The Traitor and the Spy* (1953). (H. H. P.)

ARNOLD, SIR EDWIN (1832–1904), English poet, scholar and journalist best known for his epic poem *The Light of Asia*, was born at Gravesend, Kent, on June 10, 1832, and educated at King's college, London, and University college, Oxford. He was principal of the government college at Poona, India, from 1856 to 1861, when he joined the *Daily Telegraph*, of which he became chief editor in 1873. A brilliant journalist, he was nevertheless better known to his contemporaries as the author of *The Light of Asia* (1879), a poem in elaborate language on the life and teaching of Buddha. This was followed by *The Light of the World* (1891), on the Christian theme, which was not successful. Arnold also published many prose works, including *Education in India* (1860), *Seas and Lands* (1891) and *The Queen's Justice* (1899). He died in London on March 24, 1904.

His *Poetical Works* appeared in 8 vol. (1888).

ARNOLD, HENRY HARLEY (1886–1950), commanding general of U.S. army air forces in World War II, was born at Gladwyne, Pa., on June 25, 1886. After graduation from the U.S. Military academy in 1907, Arnold served in the infantry and then transferred to the aeronautical section of the signal corps, receiving his flying instruction from Orville Wright in 1911.

During World War I he rose from the grade of captain to colonel and was eventually the executive officer to the chief of the air service. In the decade of demobilization and disarmament after the war, he was one of the apostles of air power, following the lead of Brig. Gen. William Mitchell (*q.v.*). In 1931 he was appointed commanding officer of the first wing, G.H.Q. air force where he originated and tested the organization and tactics later employed in World War II.

Arnold reported to Washington in 1936 as assistant chief of the air corps. When his superior, Gen. Oscar Westover, was killed in a plane crash (1938) Arnold succeeded him as chief of the air corps. Anticipating the coming conflict, Arnold strongly pressed for increased air corps appropriations and aid to the Allies against isolationist hostility and military myopia. In 1941 he published, in collaboration with Gen. Ira C. Eaker, a book entitled *Winged Warfare*.

During World War II Arnold was commanding general of the U.S. army air forces throughout the world. He also served as the U.S. air representative on the U.S. joint chiefs of staff and the Allied combined chiefs of staff. In these capacities he was an influential architect of the plans and strategy which resulted in Allied victory. In Dec. 1944 he was one of four army leaders promoted to the five-star rank, general of the army. His title was later changed to general of the air force.

Arnold had long planned and advocated that the air forces have parity with the army and navy in the U.S. military establishment. The National Defense act of 1947, authorizing this organization, was undoubtedly due in no small degree to Arnold's effort and influence. (*See* Air Power.) He died at his retirement home, Sonoma, Calif., Jan. 15, 1950. (I. C. E.)

ARNOLD, MATTHEW (1822–1888), English poet, critic,

and inspector of schools, was born at Laleham, Middlesex, on Dec. 24, 1822. He was the eldest son of the famous Dr. Thomas Arnold (*q.v.*), who was appointed headmaster of Rugby in 1828. From his mother, Mary (née Penrose), he inherited Cornish blood, and with it something of what he would have distinguished as the "Celtic" strain in his sensibility. After a year at Winchester, Matthew Arnold entered Rugby school (1837). His first publication was a Rugby prize poem, *Alaric at Rome* (1840). He went up to Oxford as a scholar of Balliol college in 1841, won the Newdigate prize with his poem *Cromwell* (1843), and graduated with second-class honours in 1844. At Oxford, probably in half-reaction from the earnestness of his father's Rugby, he affected a certain dandyism and ironic detachment, and struck some of his contemporaries as a trifler. But—like his friend Arthur Hugh Clough (*q.v.*)—he was elected to a fellowship at Oriel (1845). Arnold's levity was only a mask; though, actually, "radiant, adorn'd outside," he had even then "a hidden ground of thought and of austerity within." Far from breaking with his father, he reverenced him, and spent much of his later life in advocating and furthering his educational and religious aims. For Oxford, too, Arnold retained an impassioned affection. His Oxford was the Oxford of John Henry Newman—of Newman just about to be received into the Roman Church; and although Arnold's own religious thought, like his father's, was strongly liberal, Oxford and Newman always remained for him joint symbols of spiritual beauty and culture. Oxford, like Newmanism, might be a part of the dead or dying world; it might be "the home of lost causes and impossible loyalties" and yet: "steeped in sentiment as she lies, spreading her gardens to the moonlight, and whispering from her towers the last enchantments of the Middle Age, who will deny that Oxford, by her ineffable charm, keeps ever calling us nearer to the true goal of all of us, to the ideal, to perfection?"

In 1847 Arnold became private secretary to Lord Lansdowne, president of the council during Lord John Russell's Liberal ministries. And in 1851, in order to secure the income needed for his marriage (June 1851) with Frances Lucy Wightman, he accepted from Lansdowne an appointment as inspector of schools. This was to be his routine occupation until within two years of his death, and it has often been thought an incongruous task for so rare and sensitive a spirit. The incessant traveling in all weathers, and the constant exposure not only to provincial hotels but to provincial rawness, Philistinism and Dissent, certainly cost him much in fatigue and lassitude. Yet education was in his blood, and he loyally (if stoically) accepted the role of propagandist and missionary for culture and for state schools. Indeed, his fame as poet and critic should not lead us, as it has often done, to forget the extent and significance of his educational work. At a time when state action of any kind was regarded with suspicion as "interference," he saw the vital necessity in a modern democracy of organizing public education, primary and secondary, for the middle classes and for the populace. Always critical of Victorian insularity and *laissez faire*, and always eager to correct British national complacency from a European standpoint, he made it his business to point out to his countrymen what had already been done in this direction on the continent. He was several times sent by the government to inquire into the state of education in France, Germany, Holland and Switzerland, and his reports show how conscientiously he devoted some of his best energies to the work. For example, in 1859, as foreign assistant commissioner, he prepared for the duke of Newcastle's commission a report (printed 1860) which was afterward (1861) reprinted in the book called *The Popular Education of France, with notices of that of Holland and Switzerland.* In 1865 he was again employed as assistant commissioner by the Schools Enquiry commission under Lord Taunton; and his report *On Secondary Education in Foreign Countries* (1866) was reprinted under the title *Schools and Universities on the Continent* (1868). A later inquiry into specific problems resulted in a parliamentary paper (1886). His annual reports on schools at home, of which 20 were collected by Sir Francis (afterward Lord) Sandford (1889; new ed., with added material and introduction by F. S. Marvin, 1908), attracted wider attention than most "Blue Book" productions, for they were written, not in officialese, but in Arnold's own urbane and civilized prose. Though all this routine work could have been done by lesser men, it is salutary to remember that Arnold did it, especially as a corrective to the notion of him as the "elegant Jeremiah," or the aloof and superior exponent of "culture."

The work which gives Arnold his high place in the history of literature and the history of ideas was all accomplished in the time he could spare from his official duties. Yet there is a unity in his whole output; his verse and his literary, social and religious criticism, no less than his educational reports, proceed from a consciousness exposed to the *Zeitgeist* ("spirit of the age"); a sensibility quick to feel, and an intelligence alert to diagnose, the deeper maladies of the age. His first volume of verse was *The Strayed Reveller, and other Poems, by A.* (1849); this was followed (in 1852) by another under the same initial: *Empedocles on Etna, and other Poems.* In 1853 appeared the first volume of poems published under his own name; it consisted partly of poems selected from the earlier volumes, and also contained the well-known preface explaining (*inter alia*) why *Empedocles* was excluded from the selection: it was a dramatic poem "in which the suffering finds no vent in action," in which "everything is to be endured, nothing to be done." This preface foreshadows his later criticism in its insistence upon the classic virtues of unity, impersonality, universality and architectonic power, and upon the value of the classical masterpieces as models for "an age of spiritual discomfort"—an age "wanting in moral grandeur." Other editions followed; and *Merope,* Arnold's classical tragedy, appeared in 1858, and *New Poems* in 1867. After that date, though there were further editions, Arnold wrote little more verse.

As a poet, Arnold must surely rank amongst the first four or five of his time. In a letter to his mother, written in 1869, he sums up his own poetic achievement thus: "My poems represent, on the whole, the main movement of mind of the last quarter of a century, and thus they will probably have their day as people become conscious to themselves of what that movement of mind is, and interested in the literary productions which reflect it. It might be fairly argued that I have less poetical sentiment than Tennyson, and less intellectual vigour and abundance than Browning; yet, because I have perhaps more of a fusion of the two than either of them, and have more regularly applied that fusion to the main line of modern development, I am likely enough to have my turn, as they have had theirs." He not only "had his turn," but has continued to hold his place as, if not the most admired, yet for many readers the most congenial, of the Victorian poets; as the poet who addresses them with the voice of a human contemporary speaking directly to their condition. Not much of Arnold's verse will stand the test of his own criteria; far from being classically poised, impersonal, serene and grand, it is often intimate, personal, full of romantic regret, *Weltschmerz* and nostalgia. As a public and social character, and as a prose writer, Arnold was sunny, debonair and sanguine; but beneath ran the current of his buried life, and of this much of his poetry is the echo:

> From the soul's subterranean depth upborne
> As from an infinitely distant land,
> Come airs, and floating echoes, and convey
> A melancholy into all our day.

"I am past thirty," he wrote to Clough in 1853, "and three parts iced over." The impulse to write poetry came typically when

> A bolt is shot back somewhere in the breast,
> And a lost pulse of feeling stirs again.

Though he was "never quite benumb'd by the world's sway," these hours of insight became more and more rare, and the stirrings of buried feeling were associated with moods of regret for lost youth, regret for the freshness of the early world, moods of self-pity, moods of longing for

> The hills where his life rose
> And the sea where it goes.

At Fox How, Thomas Arnold's holiday home in Westmorland, Matthew's earlier life had been steeped in Wordsworthian sentiment; he knew and revered the aged poet himself, who lived a

stone's throw away at Rydal Mount. And Arnold may be thought of as a Victorian Wordsworth—a Wordsworth exiled from the hills, dwelling on lower reaches of the river of Time, further from the sources of life and inspiration, and moved to yearning rather than to rapture by Nature's grandeur, calm and self-dependence. Yet, though much of Arnold's most characteristic verse is in this vein of soliloquy or intimate confession, he can sometimes rise, as in *Sohrab and Rustum*, to epic severity and impersonality; to lofty meditation, as in *Dover Beach;* and to sustained magnificence and richness, as in *The Scholar-Gypsy* and *Thyrsis*—where he wields an intricate stanza form without a stumble.

In 1857, assisted by the vote of his godfather (and predecessor) John Keble, Arnold was elected to the Oxford chair of poetry, which he held for 10 years. It was characteristic of him that he revolutionized this professorship, lecturing in English instead of Latin, and concerning himself, not with "the trade in classic niceties," but (in Lionel Trilling's phrase) "with the demand which humanity makes for a poetry *adequate* to the time in which it is written." (Lionel Trilling, *Matthew Arnold*, George Allen & Unwin Ltd.) The keynote was struck in the title and contents of his inaugural lecture: "On the Modern Element in Literature"; "modern" being taken to mean not merely "contemporary" (for Greece was "modern"), but the spirit which, contemplating the vast and complex spectacle of life, craves for moral and intellectual "deliverance." Several of the lectures were afterward published as critical essays, but the most substantial fruits of his professorship were the three lectures *On Translating Homer* (1861), in which he recommends Homer's plainness and nobility as medicine for the modern world, with its "sick hurry and divided aims," and condemns Francis Newman's recent translation as ignoble and eccentric; and the lectures *On the Study of Celtic Literature* (1867), in which, without much knowledge of his subject or of anthropology, he uses the "Celtic" strain as a symbol of that which rejects the despotism of the commonplace and the utilitarian.

It is said that when the poet in Arnold died, the critic was born; and it is true that from this time onward he turned almost entirely to prose. But in fact the critic had been alive in him from the start, and his poetry had itself been the outcome of his effort to apply intelligence, as well as feeling, to the problem of "the world's multitudinousness." It is a mark of Arnold's distinction and many-sidedness that, instead of writing more and worse poetry, he went on to produce those essays which place him first among Victorian critics, and high among those few European critics who have permanently influenced the course of opinion about the nature and function of poetry. In Arnold appears what is virtually a new phenomenon: the "literary" intelligence playing freely upon the great concerns of human life. He saw and proclaimed the importance, for the modern world, of those qualities of mind and spirit which literary culture can give; and literary criticism has gained immensely from his expansion of its scope. There is only space here to consider some of the leading ideas and phrases put into currency in *Essays in Criticism* (First Series, 1865; Second Series, 1888) and *Culture and Anarchy* (1869). The first essay in the 1865 volume, "The Function of Criticism at the Present Time," is an overture announcing briefly most of the themes he developed more fully in later work. It is at once evident that he ascribes to "criticism" a scope and importance hitherto undreamed of. The function of criticism, in his sense, is "a disinterested endeavour to learn and propagate the best that is known and thought in the world, and thus to establish a current of fresh and true ideas." It is in fact a spirit that he is trying to foster, the spirit of an awakened and informed intelligence playing upon not "literature" merely, but theology, history, art, science, sociology and politics; and in every sphere seeking "to see the object as in itself it really is." In this critical effort England has lagged woefully behind France and Germany, and the English have accordingly remained in a backwater of provinciality and complacency. Even the great Romantic poets, with all their creative energy, suffered from the want of it. "Life and the world being in modern times very complex things, the creation of a modern poet, to be worth much, implies a great critical effort behind it." The English literary critic must know other literatures than his own and be in touch with European standards. This last line of thought he develops in the second essay, "The Literary Influence of Academies," where he dwells upon "the note of provinciality" in English literature, caused by remoteness from a "centre" of correct knowledge and correct taste. To realize how Arnold widened the horizons of "criticism" it is enough to glance at the titles (but better to read the contents) of some of the other essays in this volume: "Maurice and Eugénie de Guérin," "Heine," "Joubert," "Spinoza and the Bible," "Marcus Aurelius"; in all these, as increasingly in his later books, he is "applying modern ideas to life" as well as to letters, and "bringing all things under the point of view of the nineteenth century."

The first essay in the 1888 volume, "The Study of Poetry," was originally published as the general introduction to T. H. Ward's anthology, *The English Poets* (1880). It contains many of the ideas for which Arnold is best remembered. In an age of crumbling creeds, poetry will have to replace religion. More and more, mankind will "turn to poetry to interpret life for us, to console us, to sustain us." Therefore we must know how to distinguish the best poetry from the inferior, the genuine from the counterfeit; and to do this we must steep ourselves in the work of the acknowledged masters, using as "touchstones" passages exemplifying their "high seriousness," and their superiority of diction and movement. The remaining essays, with the exception of the last two (on Tolstoy and Amiel), all deal with English poets: Milton, Gray, Keats, Wordsworth, Byron and Shelley. All contain memorable things, and all attempt a serious and responsible assessment of each poet's "criticism of life," and his value as food for the modern spirit. Arnold has been taken to task for some of his judgments and omissions; for his judgment that Dryden and Pope were not "genuine" poets because they composed in their wits instead of "in the soul"; for calling Gray a "minor classic" in an age of prose and spiritual east winds; for paying too much attention to the man behind the poetry (Gray, Keats, Shelley); for making no mention of Donne; and above all for saying that poetry is "at bottom a criticism of life." On this last point it should be remembered that he added "under the conditions fixed . . . by the laws of poetic truth and poetic beauty," and that if by "criticism" is understood (as Arnold meant) "evaluation," Arnold's dictum is seen to have wider significance than has been sometimes supposed.

Culture and Anarchy (1869) is in some ways Arnold's most central work. It is an expansion of his earlier attacks, in "The Function of Criticism" and "Heine," upon the smugness, Philistinism and mammon-worship of Victorian England. Culture, as "the study of perfection," is opposed to the prevalent "anarchy" of a new democracy without standards and without sense of direction. By "turning a stream of fresh thought upon our stock notions and habits," culture seeks to make "reason and the will of God prevail." Arnold's classification of English society into Barbarians (the aristocracy: with their high spirit, serenity and distinguished manners, and their inaccessibility to ideas); Philistines (the great middle class, the stronghold of Dissent, with plenty of energy and morality, but insufficient "sweetness and light"); and Populace (the masses, still raw and blind), is well known. Arnold saw in the Philistines the key to the whole position; they were now the most influential section of society; their strength was the nation's strength, their crudeness its crudeness: Educate and humanize the Philistines, therefore! Remedy their excessive Hebraism by a dose of Hellenism! Arnold saw in the idea of "the State," and not in any one class of society, the true organ and repository of the nation's collective "best self." No summary can do justice to this extraordinary book; it can still be read with pure enjoyment, for it is written with an inward poise, a serene detachment, and an infusion of mental laughter, which make it a masterpiece of ridicule as well as a searching analysis of Victorian society. The same is true of its unduly neglected sequel, *Friendship's Garland* (1871).

Lastly Arnold turned to religion, the constant preoccupation and true centre of his whole life, and wrote *St. Paul and Protestantism* (1870); *Literature and Dogma* (1873), *God and the Bible* (1875) and *Last Essays on Church and Religion* (1877). In these undeservedly neglected books Arnold really founded Anglican

"modernism." Like all religious liberals, he came under fire from two sides: from the orthodox, who accused him of infidelity, of turning God into a "stream of tendency" and of substituting vague emotion for definite belief; and from the infidels, for clinging to the Church and retaining certain Christian beliefs of which he had undermined the foundations. To Arnold himself, it seemed that his religious writings were constructive and conservative. Those who accused him of destructiveness did not realize how far historical and scientific criticism had already riddled the old foundations; and those who accused him of timidity failed to see that religion is the highest form of culture, the *unum necessarium* (one indispensable) without which all secular education is in vain. His attitude is best summed up in his own words (from the preface to *God and the Bible*): "At the present moment two things about the Christian religion must surely be clear to anybody with eyes in his head. One is, that men cannot do without it; the other, that they cannot do with it as it is." Convinced that much in popular religion was "touched with the finger of death," and convinced no less of the hopelessness of man without religion, he sought to find for religion a basis of "scientific fact," which even the positive modern spirit must accept. And of these facts none, he felt, was more unassailable than "that righteousness tendeth to life," that by repentance we may transcend our ordinary selves, and be born again in love and in discipleship to Christ. A reading of Arnold's *Note Books* will convince any reader of the depth of Arnold's spirituality, and of the degree to which, in his "buried life," he disciplined himself in constant devotion and self-forgetfulness.

Of Arnold's "triumphal tour" in the United States (1883–84) there is no room to speak (but *see* his *Discourses in America* [1885]); nor of his home and family life, nor of the charm which made him one of the most lovable of the eminent Victorians. He died suddenly, of heart failure, on April 15, 1888, at Liverpool, and was buried at Laleham, with the three boys whose early loss had shadowed his life.

See also Index references under "Arnold, Matthew" in the Index volume.

Bibliography.—The first collected edition of Arnold's poems was published in 1869; other editions appeared in 1877 and 1881; and a library edition in 1885. A new and complete edition was published in "Oxford Standard Authors Series" (1950), ed. by C. B. Tinker and H. F. Lowry, who also edited *The Poetry of Matthew Arnold, A Commentary* (1940). *Arnold's Letters (1848–1888)*, collected and arranged by G. W. E. Russell (1895, reprinted 1901); Arnold Whitridge (ed.), *Unpublished Letters* (1923); *Letters to Arthur Hugh Clough*, with an introductory study by H. F. Lowry (ed.) (1932). There is a complete edition (literary contents) of *The Note Books of Matthew Arnold*, ed. by H. F. Lowry, K. Young and W. H. Dunn (1952). An edition de luxe of Arnold's complete *Works*, 15 vol. (1903–04) includes a bibliography by T. B. Smart, who published a separate bibliography in 1892. For a more recent bibliography *see* T. G. Ehrsam and R. H. Deily, *Bibliographies of Twelve Victorian Authors* (1936; suppl. by J. G. Fucilla, in *Modern Philology*, xxxvii, 1939). This gives a full bibliography of Arnold's essays, contributions to periodical literature and editions of and introductions to literary works.

It was Arnold's expressed desire that his biography should not be written; there are, however, a number of monographs and biographico-critical works, among them Lionel Trilling, *Matthew Arnold* (1939), the best full-length study; J. Dover Wilson, *Leslie Stephen and Matthew Arnold as Critics of Wordsworth* (1939); Sir E. K. Chambers, *Matthew Arnold; a Study* (1947); J. D. Jump, *Matthew Arnold*, "Men and Books Series" (1955).

Essays on Arnold: Henry Sidgwick, *Miscellaneous Essays and Addresses* (1904); T. S. Eliot in *The Use of Poetry and the Use of Criticism* (1932–33) and "Arnold and Pater" in *Selected Essays* (1953); Basil Willey in *Nineteenth Century Studies* (1949); Merle M. Bevington in *M. Arnold's "England and the Italian Question"* (1953); John Holloway in *The Victorian Sage* (1953). (B. Wy.)

ARNOLD, SAMUEL (1740–1802), English composer and editor of the works of Handel. Born in London, Aug. 10, 1740, and educated at the Chapel Royal, he became composer to Covent Garden theatre, where in 1765 he produced *The Maid of the Mill.* In 1777 he became music director of the Theatre Royal, Haymarket. Between 1765 and 1802, when he died (in London, Oct. 22), he composed music for nearly 100 successful musical productions—ballad operas, farces and pantomimes—and also published sonatas, symphonies and oratorios, the most important being *The Prodigal Son* (1773), and anthems for the Chapel Royal to which he became organist and composer in 1783. In 1793 he was appointed organist at Westminster abbey.

Arnold's fame, however, rests on his edition of the works of Handel (1787–97), which, although defective in the light of later scholarship, merits respect as the earliest attempt to publish an edition of a composer's complete works. His *Cathedral Music* (1790) was intended as a supplement to William Boyce's collection. His own music is facile, although one or two symphony overtures and several of his harpsichord lessons have charm. (Cs. Ch.)

ARNOLD, THOMAS (1795–1842), headmaster and reformer of Rugby school, was born at East Cowes in the Isle of Wight, Eng., on June 13, 1795. He was educated at Winchester and Corpus Christi college, Oxford, and was elected a fellow of Oriel in 1815. After ordination and marriage he settled at Laleham, Middlesex, in 1819 as a tutor to university entrants. His application for the vacant headship of Rugby in 1827 was supported by Edward Hawkins, shortly to become provost of Oriel, who wrote that if Arnold were elected, "he would change the face of education all through the public schools of England."

Arnold was not an innovator in teaching method; his aim was to reform Rugby by making it a school for Christian gentlemen, and he is chiefly remembered for his sermons in the school chapel. Although he did not originate the prefect system, he used prefects more fully than any previous headmaster. After him this system was adopted in countless English secondary schools. Arnold's influence survived him, and the Arnold tradition spread to other schools through Rugby pupils and masters appointed to them. Many of the new schools established after his death were modeled on Rugby. Arnold died suddenly at Rugby on June 12, 1842.

Bibliography.—Arthur Penrhyn Stanley, Dean of Westminster, *The Life and Correspondence of Thomas Arnold*, 2 vol. (1844; 12th ed., 1881); Sir Joshua Fitch, *Thomas and Matthew Arnold, and Their Influence on English Education* (1897); Norman Wymer, *Dr. Arnold of Rugby* (1953). (S. J. C.)

ARNOLDSON, KLAS PONTUS (1844–1916), Swedish writer and politician, was awarded the Nobel peace prize in 1908, jointly with Fredrik Bajer. Arnoldson was born in Göteborg, Swed., on Oct. 27, 1844. He became a railway clerk and, from 1871, a stationmaster. In 1881, however, he gave up his post on the railways and from that time devoted himself entirely to the causes he had at heart. In 1881 also he was elected to the Swedish *riksdag*. In politics Arnoldson was a radical, in religion a believer in practical Christianity without dogma; above all he was a passionately convinced pacifist. He supported the neutrality of the Nordic countries and in 1883 helped to found the Swedish Association for Peace and Conciliation. His greatest contribution to peace, however, was made in helping to solve the problems of the Norwegian-Swedish union. From about 1890, when the conflict of views in the two countries was critical, Arnoldson used all his powers, including his gift for inspiring oratory, to form a public opinion in both Norway and Sweden that would support a peaceful settlement. In 1905 he saw the result of his work in the agreed dissolution of the union.

Arnoldson edited several daily newspapers and wrote a number of books. He died in Stockholm on Feb. 20, 1916.

ARNOLFO DI CAMBIO (*c.* 1245–1302), Florentine sculptor and architect, who designed the Duomo in Florence, is mentioned in 1265 and 1267–68 as an assistant of Niccolò Pisano in work on the pulpit in Siena cathedral. In 1277 he was active in Rome in the service of Charles of Anjou. From this period the disassembled monument of Cardinal Annibaldi in St. John Lateran (effigy in the church, other fragments in the cloister) and the tomb of Pope Adrian V in S. Francesco, Viterbo, may be dated. In 1281 he was engaged on a fountain at Perugia, figures from which survive in the Galleria Nazionale dell'Umbria. Immediately after he constructed the monument of Cardinal de Braye (d. 1282) in S. Domenico at Orvieto, and two ciboria in Rome in S. Paolo fuori le Mura (1285) and Sta. Cecilia in Trastevere (1293). In 1296 Arnolfo returned to Florence to undertake his most important commission, the building of the Duomo or cathedral. He is mentioned in Florence in 1300 and appears to have died there in 1302.

One of the greatest Italian sculptors, Arnolfo developed a nota-

bly individual style, which reached full maturity in the magnificent sculptures of the De Braye monument. Unlike his contemporary Giovanni Pisano, he was relatively unresponsive to the impact of French Gothic forms and was strongly influenced by the antique. His latest works, the statues carved for the façade of the cathedral in Florence, now in the Museo dell'Opera del Duomo, are some of the noblest sculptures of their time. In his own day Arnolfo was famous as an architect, and he is traditionally credited not only with the design of the cathedral in Florence but with the choir of the Badia, the church of Sta. Croce and the Palazzo della Signoria. The validity of these attributions and the exact extent of his work in the cathedral are uncertain, but he seems to have been responsible for imposing on Florentine Gothic architecture the austere character that it retained throughout the 14th century.

Gnudi, *Nicola, Arnolfo, Lapo* (1948); W. Paatz, *Werden und Wesen der Trecento-Architektur in Toskana* (1937); V. Mariani, *Arnolfo di Cambio* (1943).
(J. W. P.-H.)

ARNOULD, (MADELINE) SOPHIE (1744–1802), French actress and operatic singer, was born in Paris, where, from her debut in 1757 to her retirement in 1778, she enjoyed almost unrivaled popularity. In Gluck's *Iphigénie en Aulide* and *Orphée* she created the parts of Iphigénie and Eurydice.

ARNSTADT, a town of Germany which after partition of the nation following World War II was located in the district of Erfurt of the German Democratic Republic, about 16 mi. S.W. of Erfurt on the Gera river on the northern edge of the Thuringian forest. Pop. (1959 est.) 26,486. Northward rise the castle-crowned peaks, the Drei Gleichen (Three Alike). Arnstadt is known for its glove-manufacturing industry; there are also leather-processing, glass, wood-finishing and engineering works, shoe factories and foundries. There are many holiday and convalescent homes belonging to the Confederation of Free German Trade Unions. Arnstadt dates from the 8th century and became a town in 1266. It was bought in 1306 by the counts of Schwarzburg who lived there until 1716. The 13th-century Liebfrauenkirche is Romanesque and the town hall was built in 1583–85.

ARNULF (*c.* 850–899), East Frankish king and last of the Carolingian emperors. An illegitimate son of Carloman, king of Bavaria, he received the march of Carinthia from his father but was excluded from the succession to the kingdom on Carloman's death. Arnulf maintained and consolidated his frontiers, though in constant tension with the Great Moravian kingdom of Svatopluk. In Nov. 887, at Frankfurt, the East Frankish magnates revolted against the incompetent emperor Charles III, who since 885 had been ruling the reunited Carolingian empire, and Arnulf became their leader. Charles yielded without a battle. The West Franks, Burgundy and Italy, however, would not recognize Arnulf but elected new kings from their own nobility. Thus ended an epoch in European history when the Carolingian empire was finally disintegrated. Arnulf, whose base of operations remained in Bavaria, nevertheless successfully defended his authority in Lotharingia west of the Rhine and even maintained a loose feudal authority over the other kings. He was an energetic ruler whose lordship was acknowledged even by the sons of Svatopluk after their father's death (894). In 891 he defeated the Vikings, whose raids up the Rhine ended in 892. He maintained good relations with the nobility and clergy and held a synod at Tribur, near Mainz, in 895. In the same year at a diet in Worms he created his illegitimate son Zwentibold king of Lotharingia.

In 894, at the request of Pope Formosus, Arnulf had invaded Italy against Guy of Spoleto, who had had himself crowned emperor by Pope Stephen V. This first expedition produced no results, but late in 895 Arnulf forced his way to Rome. He was crowned emperor by Formosus (Feb. 896). While preparing to attack Spoleto, however, Arnulf was struck down by paralysis and had to return to Germany, whereupon his successes in Italy dissolved. This ended the hegemony of the East Frankish Carolings in Italy. Having secured the succession to his East Frankish kingdom for his four-year-old son Louis the Child by obtaining an oath of fealty from the magnates in 897, Arnulf died in Regensburg on Dec. 8, 899.

There is an edition of Arnulf's administrative documents by P. Kehr in the series *Monumenta Germaniae Historica, Dipl. Karol. Germ.*, vol. iii (1940).

Kehr, *Die Kanzlei Arnolfs* (1939); H. Kämpf, *Die Entstehung des deutschen Reiches* (1956); B. Gebhardt and H. Grundmann, *Handbuch der deutschen Geschichte*, vol. i (1954); *Cambridge Medieval History*, vol. iii (1936).
(T. Sch.)

ÁRPÁD (d. 907), founder of Hungary and of its first dynasty, son of a Magyar chieftain, Álmos, was elected prince by the heads of the seven Magyar tribes about 890. He successfully united his nomadic people and led them from the steppe lying north of the Black sea between the Don and the Dnieper across the Carpathians by way of the Veretski (Verecke) pass into the north-eastern region of what is now Hungary. This migration was completed by 896. Árpád defeated Zalán, prince of the Bulgars; Marót, prince of the Khazars; Gyalu, prince of the Vlachs; and, with the help of the Western emperor Arnulf, Svatopluk of Moravia. He soon found himself master of the middle Danube basin. He settled the Magyars in central Hungary, in the vicinity of the present city of Budapest, among the conquered tribes. He led the Magyars on numerous successful military expeditions through western countries, devastating parts of Austria, Bavaria, Italy and Switzerland. Árpád died in 907 and, according to tradition, was buried somewhere near Budapest. The male line of the Árpád dynasty became extinct in 1301. (Ge. Gr.)

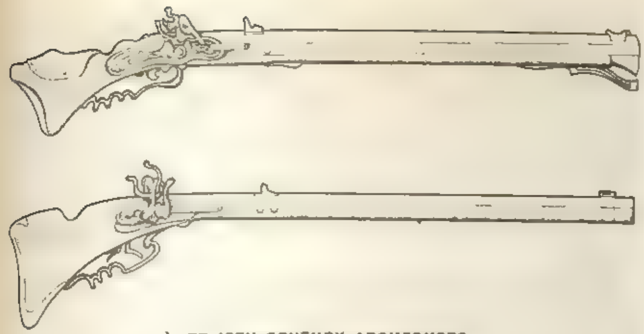
ARPAD, an ancient city identified as Tell-Erfad in north-western Syria, 15 mi. N.N.W. of Aleppo between the latter and 'Azaz. Arpad is frequently listed in the Old Testament with Hamath and other Syrian city states (II Kings xviii, 34; Isa. x, 9). It also appears frequently in Assyrian texts. In 806 B.C. Adadnirari III forced the city to pay tribute in arrear since its rebellion against his father Shamshi-Adad V. Mati-ilu of Bit-Agusi (the area of Arpad) turned against his sovereign Ashurnirari V during a period of Assyrian decline (754 B.C.) and successfully maintained his stand on the side of Sardur II of Urartu until Tiglath-pileser III defeated both Urartu and Arpad, the latter submitting only after a three-year siege (740 B.C.). Basalt blocks that have come to light since 1930 near Sefireh, southeast of Aleppo, contain three treaties from *c.* 750 B.C., made between Barga'yah, ruler of a kingdom designated as KTK, and Mati-el (Mati-ilu). Tiglath-pileser made Arpad capital of a province embracing the western half of northern Syria. Arpad followed the lead of Hamath in a revolt against Sargon II in 720 B.C., but subsequently remained loyal to Assyria. Later the city was capital of a province in the neo-Babylonian empire. (J. S. L.)

ARPINO, a town of central Italy, region of Lazio, province of Frosinone, is 1,476 ft. above sea level and 24 mi. by road east of the town of Frosinone. Pop. (1957 est.) 10,196 mun. Above the town is a castle attributed to Ladislaus of Naples (d. 1414). Nearby on a hill is Civitavecchia, where the sanctuary of the ancient Volscian town of Arpinum was situated. The remains of imposing cyclopean walls of the Volscian period surround the town. These were restored in Samnite, Roman and medieval times, and various towers and gateways were added. An interesting feature is the Porta dell'Arco, a gateway giving on to Civitavecchia. The 15th-century churches of S. Michele and S. Andrea contain pictures by Giuseppe Cesari (d. 1640) commonly known as the Cavaliere d'Arpino, for Arpino was his native place. It was also that of Caius Marius, and M. Vipsanius Agrippa, son-in-law of Augustus. The people are engaged in agriculture, woolen manufacture and the quarrying of coloured marbles.

The Romans conquered Arpinum in 305 B.C. In the middle ages it was sacked by the Longobards, the Saracens and the Hungarians. In 1215 it passed to the Church, which made its southern stronghold there. (M. T. A. N.)

ARQUEBUS, also called Harquebus, Hackbut, etc., a fire-arm of the 16th century. It was the immediate predecessor of the musket (*q.v.*).

The Spanish army was first to replace the handgun, fired from



LATE 15TH-CENTURY ARQUEBUSES

the chest, with the arquebus, which had a stock shaped so that it could be aimed from the shoulder. The improvement that most distinguished this weapon from its crude predecessor was the serpentine—a movable S-shaped clamp holding the smoldering slow-match. Pivoting on a pin, it was connected to a trigger that brought it into contact with the firing pan. The burning end of the match dipped into the priming powder, and the resulting flash ignited the coarse powder in the touchhole and discharged the piece. (*See* SMALL ARMS, MILITARY.)

The French introduced the *arquebus de calibre*, with a standard bore, but the Spanish took the lead in tactical respects. At the battle of Pavia (1525), according to Brantôme, the Marquis of Pescara owed his victory over the French to 1,500 arquebusiers trained "without word of command . . . to wheel round, to face about from this side to that, now there, with the utmost rapidity." This trend toward mobility was short-lived and the heavier musket replaced the arquebus in the last half of the 16th century. *See* TACTICS: *The Military Renaissance.* (LN. MS.)

ARRACK, RACK, or RAK is a name given to many strong, dry spirits, distilled all over the east for local consumption. It is well known in Indonesia, China, India, Ceylon, as well as in Egypt, Turkey and Greece; one variety from the East Indies, of a pale yellow colour, is exported. According to some authorities, the name is derived from the Arabic word *arak* (sweat), *i.e.*, the "sweat" or sap of a certain tree. It is more likely that it is derived from the arecanut, from which a common variety of arrack was long made in India.

Different ingredients are used according to local custom. In Ceylon, arrack is distilled from palm toddy, made from either the palmyra palm (*Borassus flabelliformis*) or the cocoa palm (*Cocos nucifera*). In India, the flowers of the mowrah or mahua tree (*Bassia latifolia*) and fermented rice or millet are generally used as well; sometimes poppy leaves and hemp are also added. The usual fermenting agent is molasses. Some arrack, especially that made in primitive conditions, has a high content of methyl alcohol and a large proportion of by-products, such as fusel oils, which make the spirit both fiery and potentially poisonous. In each case the character of the spirit will depend upon the ingredients used and the method of distillation; local arrack may be injurious, but it may be clean if scientifically distilled.

The manufacture of arrack is diminishing, owing to the wider distribution of more commercial spirits, such as vodka and brandy. Much of the arrack that is manufactured is used (*e.g.*, in India) for industrial purposes. (C. C. H. F.)

ARRAH, a town and headquarters of Shahabad district in Bihar, India, lies 31 mi. W. of Patna and 10 mi. S. of the Ganges. Pop. (1951) 64,205. Area 4 sq.mi. The town has generally one-story buildings and narrow streets. There are three colleges, the library of one of which is in the famous "Little House" at Arrah, a small building defended by the British against Babu Kuar Singh, a leader of the Sepoy uprising of 1857. There is a large playground between the town and courts. Arrah is at the junction of the main line of the Eastern railway with Arrah-Sasaram light railway. (E. AH.)

ARRAN, EARLS OF. The extinct Scottish title of the earls of Arran (not to be confused with the modern Irish earls of Arran, a title created in 1762) was borne by some famous characters in Scottish history. With the exception of Thomas Boyd (d. *c.* 1473), for whom the title was created (*see* BOYD), and of James Stewart (*see* below), all the earls belonged to the Hamilton family.

JAMES HAMILTON (1475?–1529), 1st earl, was the son of James, 1st Lord Hamilton, and of Mary, daughter of James II of Scotland, and was created earl of Arran in 1503 on the occasion of the marriage of James IV with Margaret Tudor. He commanded a naval expedition against England in 1513, but failed lamentably and returned to find his rival, the earl of Angus, supreme at court. He therefore allied with the duke of Albany, regent for James V, and was himself from 1517 to 1520 one of six vice-regents. But in the feuds of these years he had no fixed allegiance. His most spectacular encounter was the fierce fight between the Hamiltons and the Douglases in the streets of Edinburgh known as "Cleanse the Causeway" (1520). When James V freed himself from the power of Angus in 1528, Arran joined him at Stirling. He died at Kinneil in 1529.

JAMES HAMILTON (*c.* 1517–1575), 2nd earl of Arran, was heir presumptive to the throne after the accession of Mary Stuart in 1542, and was appointed governor and tutor. He negotiated for a marriage between Mary and Prince Edward (afterward Edward VI of England), but suddenly abandoned the project and joined the French party. He then agreed to the marriage of Mary with the dauphin of France, receiving the title of duc de Châtelherault at this time (1549); and he resigned office in 1554 in favour of the queen dowager, Mary of Lorraine. On the outbreak of the Scottish Reformation he joined the lords of the congregation (1559) and became the acknowledged leader of the Protestant party. He was exiled in 1565 but he returned to Scotland in 1569 to support the queen's cause, not accepting the fact of Mary's abdication and the regency for her son James VI until 1573. He died at Hamilton, Lanarkshire, on Jan. 22, 1575.

JAMES HAMILTON (1537?–1609), 3rd earl of Arran, was twice considered as a husband both for Mary Stuart and for Henry VIII's daughter Elizabeth (afterward Elizabeth I). During his childhood these projects arose from his father's ambitions; later, when he had returned from commanding the Scots guards in France (1554–59) and had joined the lords of the congregation, the Protestants proposed him as suitor first for the hand of Elizabeth, and then, after Dec. 1560, for that of Mary. He showed signs of insanity in 1562 and the rest of his life was spent in confinement. He died in 1609.

During the insanity of the 3rd earl, his honours were claimed, and for a short time enjoyed, by his cousin, JAMES STEWART, known as earl of Arran from 1581 to 1585. Both he and his rival, the duke of Lennox, were deprived of office when the Protestant lords seized power by the raid of Ruthven (1582); but a year later they in turn were overthrown and driven into exile by Stewart. But his tyranny and insolence alienated many and caused his rapid fall from power. He was accused by Elizabeth I of the murder of Lord Russell on the border in July 1585 and was imprisoned; the banished lords returned and Stewart, proclaimed a traitor, fled in Nov. 1585. From that time his movements are uncertain. He was ordered to leave Scotland in 1586 but may not have done so, and he returned to Edinburgh in 1592 and managed to have himself reinstated at court. He was assassinated near Symington by Sir James Douglas, nephew of the regent Morton whose imprisonment and execution in 1581 he had precipitated.

JOHN (1532–1604), brother of the 3rd earl, became 1st marquess of Hamilton in 1599, and thereafter the Arran peerage was merged in that title. *See* HAMILTON.

See *The Manuscripts of the Duke of Hamilton* (Historical Manuscripts Commission, 1887); G. Hamilton, *History of the House of Hamilton* (1933). (G. S. P.)

ARRAN, the largest island of Buteshire, Scot., at the mouth of the Firth of Clyde. Its greatest length, from the Cock of Arran to Bennan head, is about 20 mi., and the greatest breadth—from Drumadoon point to Kingscross point—is 11 mi. Area 166 sq.mi. Pop. (1961) 3,705.

The scenery of Arran is very fine, and the geological structure complex. The greatest elevations are found in the north, where Goatfell reaches 2,866 ft. The name of this hill is said to be a corruption of the Gaelic *Goadh Bhein,* "Mountain of the Winds."

It belongs to the series of intrusive igneous rocks of Tertiary age—granites—which occupy most of the northern half of the island and form its grandest natural features. These rocks are partly surrounded by an incomplete ring of the oldest rocks in the island—slate, mica-schists and grits—while in the south the rocks are mainly Triassic, the sedimentary rocks, however, being metamorphosed or broken at many points by volcanic intrusions. The island is a favourite place for students of geology.

Many beautiful glens, notably Glen Rosa and Glen Sannox, score the flanks of the mountains, and Lochranza, an inlet in the north, is one of the finest sea-lochs in Scotland. The streams or "waters," as they are called, are generally hill burns, and they and their small mountain-lochs carry trout. Red grouse, pheasant, woodcock, snipe, duck and wild geese are numerous and the northern area is well stocked with red deer. The alpine hare was introduced from the mainland and "wild" goats are also found. Cattle and sheep are raised in considerable numbers.

Brodick is the chief village in Arran. Three miles south is Lamlash, on a fine bay so completely sheltered by Holy Island as to form an excellent harbour. Four miles north lies the village of Corrie, taking its name from a rugged hollow in the hill of Am Binnein (2,172 ft.) which overshadows it. Daniel Macmillan (1813–1857), the founder of the publishing firm of Macmillan and Co., was a native of Corrie.

Steamers from Ardrossan, Fairlie and Gourock communicate with the island, especially in summer when Arran receives many visitors; but some of the services are curtailed in winter. There is a coast road, 60 mi. long, around the island.

About 1½ mi. E. of Lamlash village is Holy Island, 1¾ mi. long, nearly ¾ mi. wide, with a finely marked basaltic cone rising to a height of 1,030 ft. St. Molios, a disciple of St. Columba, founded a church near the northwest point. In the saint's cave on the shore is the rocky shelf on which he lay. Off the southeast coast, 1 mi. from Port Dearg, lies the pear-shaped isle of Pladda where there is a lighthouse and telegraph station from which the arrival of vessels in the Clyde is notified to Glasgow and Greenock.

Standing stones, cairns and other antiquities occur near Tormore, on Machrie bay, Lamlash and other places. The Norse raiders found a home in Arran for a long period until the defeat of Haakon V at Largs (1263) compelled them to retire. Robert Bruce found shelter in the King's caves on the western coast. From the point still known as Kingscross he crossed over to Carrick, in answer to the signal for the supreme effort. Ruins in Glen Cloy bear the name of Bruce's castle, in which his men lay concealed. On the southern arm of Lochranza stands a picturesque ruined castle said to have been his hunting seat. In 1503 the island was awarded by royal charter to Sir James Hamilton of Cadzow, ancestor of the dukes of Hamilton. On the death of the 12th duke most of the island passed to his only daughter who married the duke of Montrose.

ARRAS, the chief town of the *département* of Pas-de-Calais, France, and seat of a bishopric, lies 38 mi. N.N.E. of Amiens on the Paris-Lille railway. Pop. (1962) 40,969. It is situated on the right bank of the Scarpe river at its junction with the little Crinchon river, now covered over. New quarters have been developed on the east, south and southwest.

Many of the old town's ancient buildings, including the 12th- to 14th-century cathedral, were destroyed in the French Revolution. Four years of fighting in World War I again destroyed the greater part of the town, including the celebrated Gothic Hôtel de Ville (16th century) with its belfry, and the abbey church (now restored as the cathedral) and abbey of St. Vaast (18th–19th century). The Hôtel de Ville was rebuilt, but the town suffered further damage in World War II. War monuments include the memorial to soldiers with no known grave (1916–18), the British military cemetery and the memorial to 200 local patriots executed 1941–44. The centre of the town is marked by its two arcaded and linked squares, the Grande Place and the Petite Place, and the town is crossed by the main east-west road. There are *lycées* for boys (18th-century Beaufort palace) and girls (15th-century Carmelite convent), and teachers' training and technical colleges. The museum is devoted mainly to tapestry and French painting, and the library contains a large number of 9th- to 15th-century manuscripts, many illuminated. Arras is a rail and road centre and is served by the tourist airport of Roclincourt. Though chiefly an administrative headquarters, the town has considerable industry including the manufacture of boilers, wagons, cycles, motorcycles, and miners' lamps; rolling and cement plants, oil works, breweries and agricultural-produce factories. For the once famous tapestry industry of Arras *see* TAPESTRY: *European Tapestry*.

History.—Arras was the principal centre of the Atrebates (whence its name), one of the last Gaulish peoples to resist Caesar. Involved in the later troubles of northeastern Gaul, it was destroyed in 407. Its bishopric was promoted by St. Vedast (Vaast) under King Clovis and had a richly endowed abbey in the 7th century. Transferred to Cambrai, the seat of the bishopric returned to Arras in 1094. The town passed to the count of Flanders in 863. The woolen industry was established there at an early date, and Arras, which became the capital of Artois (*q.v.*), had an era of great prosperity in the 12th and 13th centuries, marked by the flourishing of religious and civic communities and of trouvères and dramatists, including notably Adam de la Halle (*q.v.*). From 1110 there are records of a commune, with aldermen, which became a model for many neighbouring districts. In 1180 Arras, with Picardy, formed the dowry of Isabella, daughter of Baldwin V, count of Hainaut, on her marriage to Philip Augustus, king of France. Passing in 1384 to Philip the Bold, duke of Burgundy, Arras became implicated in the rivalry between France and Burgundy. The town gave its name to the peace of Arras (1435) between Philip the Good of Burgundy and Charles VII of France, also to the treaty of 1482 between Louis XI of France and Maximilian I which predetermined the northern frontier of modern France. From 1479 to 1484 Louis XI, after razing the walls, carried out a mass deportation of the citizens, replacing their leaders by French "managers." Charles VIII restored the town's position, and it became the object of contention between him and the Habsburg German king, Maximilian I, who married Mary the daughter of Charles the Bold of Burgundy. The peace of Senlis (1493) gave it to Maximilian and it continued under the Habsburgs until reunited with France in 1640, enjoying thereafter a new period of prosperity. Robespierre, one of the most fanatical of the leaders of the French Revolution, was born in Arras in 1758.

ARRAS, BATTLE OF, the name given to operations against the Germans by British forces in April and May 1917, during World War I, on a 20-mi. front just east of Arras, in France. The attack was a diversion to the abortive "Nivelle offensive" staged by the French further south.

After a four-day bombardment, which included gas shells, the VII corps of the 3rd army (Gen. Sir E. Allenby) attacked on April 9 and pierced the Hindenburg position, held by the German 6th army (Gen. L. von Falkenhausen) to a depth of 6,000 yd. The Canadian corps of the 1st army (Gen. Sir H. Horne) captured Vimy ridge. Between April 10 and 14, the Germans moved 11 reserve divisions to the area. Further British attacks were made on the Scarpe river (April 23 and 24), at Arleux (April 28 and 29) and again on the Scarpe (May 3 and 4). Finally the 5th army extended the battle area to the south by attacking Bullecourt on May 3, with one Australian and two British divisions. No successes comparable with the first attack were attained. On May 6, the Germans counterattacked, but with only meagre success. Sporadic fighting continued until May 15, when the battle of Arras may be said to have ended. The Australian, British and Canadian forces suffered 158,660 casualties, the German about the same number.

(C. N. B.)

ARRAU, a large turtle (*Podocnemis expansa*) of the Amazon and Orinoco basins, also called jurara. Its eggs and flesh are an important food for the regional Indians. *See* TURTLE.

ARREST, the placing of a person in custody or under restraint, usually for the purpose of compelling obedience to the law. If the arrest occurs in the course of criminal procedure, the purpose of the restraint is to hold the person for answer to a criminal charge or to prevent him from committing an offense. In civil proceedings the purpose is to hold the person to a demand made against him.

In Criminal Cases.—In Anglo-American law absolute privileges against arrest on criminal charges are recognized in only a limited number of situations. Thus, in the United States, an ambassador or minister representing a foreign nation is exempt from arrest. In England, the limitation applies to the sovereign or to a foreign sovereign. In some states in the U.S. legislators may not be arrested for certain offenses while the legislature is in session. In most states a subsequent arrest may be valid even though the person was brought into the jurisdiction by fraud or illegal force.

Although the law authorizes criminal arrests by a variety of means, the two principal types are (1) those effected pursuant to a warrant (*q.v.*); and (2) those effected without a warrant under legally specified circumstances.

A warrant of arrest may be issued by a court or judicial officer on a showing of probable cause to believe that a criminal offense has been committed and that the person charged in the warrant is probably guilty. The facts constituting "probable cause" must be stated under oath. An arrest warrant may validly be served only by the person or by a member of the class of persons to whom the warrant is addressed. In many states in the U.S. the warrant may be addressed to private persons as well as to peace officers.

At common law a warrant, and hence an arrest effected under its authority, was valid only within the geographical jurisdiction of the judicial officer who issued the warrant. The modern tendency is to relax this limitation. By virtue of the Criminal Justice act of 1925, s. 31(3), a warrant lawfully issued by a justice of the peace, charging either an offense punishable on indictment or summarily, may be executed anywhere in England or Wales. Similarly, statutes of many states in the U.S. now authorize execution of warrants throughout the state. It is usually held that the warrant must be in the possession of the officer at the time of the arrest, but there is no absolute requirement that the warrant be exhibited to the party charged before the arrest is made.

More numerous and of greater practical importance are arrests without warrant. The common-law principles relating to such arrests date from the 17th century and may be stated substantially as follows: A private person may arrest one whom he reasonably believes to have committed treason or a felony if, but only if, treason or felony has actually been committed. A private person may not arrest a misdemeanant unless the offense constitutes a breach of the peace and was committed in the presence of the person making the arrest. The peace officer's powers of arrest are broader than those of a private person in only one respect. Thus, the arrest of a person for treason or felony by a peace officer may be valid even though no such offense was actually committed, provided that the officer reasonably believed the crime to have been committed and the person arrested to be the guilty party.

Because the common law of arrest without warrant antedated development of modern systems of police and law enforcement by some 150 years, it is not surprising that efforts at legislative modification of arrest law have been made in most Anglo-American jurisdictions. Most of these statutory changes are designed to widen the scope of arrest powers, particularly those of the police. Thus, in most states in the U.S. a peace officer is authorized to arrest one committing any misdemeanour in his presence, whether or not the offense constitutes a breach of the peace. The constitutional validity of this and other legislative expansions of arrest powers has ordinarily been upheld in U.S. courts. Although the rules relating to arrests without warrant can be stated with reasonable clarity, their application in concrete situations often involves substantial difficulties. A large body of case law, not in all respects consistent, is concerned with what constitutes "reasonable belief" in various situations. The phrase "in the presence" has usually been interpreted as including not only cases in which the offense occurs within the sight of the arresting party but also those in which he detects commission of an offense through his sense of smell or hearing.

In addition to arrests with or without warrant, valid arrests may be effectuated by other means. Thus an indictment provides sufficient warrant for arrest of the accused, since the return of an indictment by the grand jury constitutes a finding of "probable cause." At common law a bondsman who has provided security for the release of a person on bail may arrest and return such person to custody. Vestiges of the old common-law arrest by hue and cry are found in the statutes of some Anglo-American jurisdictions. Arrests may be made of persons on probation or parole who have violated the conditions of their release, even though such violations do not involve commission of criminal acts. In many cases of minor offenses the accused is not arrested but is notified of the pending criminal proceedings by summons. The familiar "traffic ticket" is one example of a summons.

A decision as to whether the arrest made in a particular case was valid may result in a variety of important legal consequences. Thus a person subjected to unlawful arrest may recover damages in a civil suit against the arresting party. In some circumstances force, even deadly force, may be employed to effect a valid arrest. If, however, the arrest attempted was invalid, the arresting party loses his justification for the use of force and may thereby incur criminal liability. It is generally recognized that a search of the person arrested and of the premises on which the arrest occurred is authorized when "incident to" a lawful arrest. But if the arrest is unlawful, the search is also invalid. A 1961 decision of the U.S. supreme court requires that evidence obtained from defendants by unlawful searches and seizures be barred from criminal proceedings in all state and federal courts. In some situations illegal arrest practices may render a confession of the defendant inadmissible at the trial. Thus in the U.S. federal courts an arrested person must be brought before a magistrate "without unreasonable delay." The U.S. supreme court has held that even a voluntary confession of an arrested party is inadmissible if made in a period of unreasonable delay before he was brought before a magistrate. This rule of the federal courts (popularly known as the Mallory rule) has not been adopted by any of the state systems of criminal justice.

In Civil Cases.—Arrest in civil actions, where authorized, is an auxiliary remedy designed (1) to bring one against whom a demand has been made within the jurisdiction of the court; or (2) to keep the person within the reach of the court's final process and to obtain from him satisfaction of the court's order or judgment.

The use of arrest as a device to compel the appearance of the defendant in a civil suit has a long history in the Anglo-American law. In the early common law no provision was made for default judgments, it being assumed that the court lacked jurisdiction to enter a judgment when the defendant had failed to appear before the court. Much attention was therefore given to devices to compel the appearance of the defendant. In the court of common pleas a succession of writs of increasing severity was made available for this purpose, including the summons and attachments or distress of the defendant's property. If in a suit involving breach of peace, such as trespass, the sheriff returned that the defendant had no property or that attachment had not compelled his appearance, the plaintiff was granted a writ of *capias ad respondendum* for seizure of the defendant's person. Beginning in the middle of the 13th century a series of statutes was enacted making the *capias* available in other actions, so that the writ was ultimately employed in virtually all civil actions. Moreover, the practical effect of the legislation was to relieve the plaintiff of the requirement of first resorting to other devices for compelling the defendant to appear. A somewhat similar development occurred in the court of king's bench and the court of exchequer. The hardships caused by arrest as the mode of initiating civil litigation ultimately produced dissatisfaction. In the 18th century the courts were by statute first granted powers to enter default judg-

ments. Since possession of this power made presence of the defendant no longer essential to the court's jurisdiction, the importance of the *capias* as a method of initiating litigation steadily declined. By an act of 1838 arrest to initiate suit was completely eliminated, although the law still provided for arrest of the defendant by court order after commencement of the suit upon a finding that the defendant was about to leave England. In the United States the laws of some jurisdictions authorize the issuance of a *capias ad respondendum* or a statutory equivalent in such actions as those on contract or for repayment of money where fraud or breach of fiduciary obligation is alleged. Many U.S. jurisdictions authorize arrest of debtors who are about to abscond or leave the state with intent to avoid payment of their debts.

To be distinguished from the use of the *capias* as a method to establish the court's jurisdiction is the use of arrest and detention of the defendant as a device to execute the court's judgment. At common law, in those cases in which an arrest of the defendant to initiate litigation was authorized, the successful plaintiff was entitled to an execution of the judgment by use of the writ *capias ad satisfaciendum.* Under this procedure a debtor was taken and confined until he paid the debt or was otherwise discharged. In England the abuses of the system of imprisonment for debt were only slowly rectified. It was not until passage of the Debtors act of 1869 that the practice was eliminated in all except a few specified situations.

Although imprisonment for debt was practised in the American colonies before the Revolutionary War, provisions in state constitutions outlawing the procedure began to appear as early as 1776. Since that time similar provisions have been included in most of the U.S. state constitutions. These constitutional provisions have usually been interpreted as not applying to tort judgments, on the theory that imprisonment to induce payment of such a judgment is not imprisonment for debt. In most jurisdictions, however, execution upon the person in tort cases is limited to situations in which the defendant's tort involved malice or some other element of aggravation. Despite these and other limitations the U.S. law presents a rather wide range of situations in which imprisonment is authorized, although the occasions on which it can be practised vary considerably from one jurisdiction to another. One typical provision authorizes such action when the judgment debtor refuses to deliver up his estate for the benefit of creditors. Another area in which imprisonment for debt may be authorized is those situations in which the debtor's failure to pay constitutes a contempt of court.

Arrest in civil cases is today regarded as a drastic remedy. In most jurisdictions it is available only in those situations specified in the statutes and is regulated by procedures likewise specified. The Anglo-American law recognizes a series of privileges against civil arrest. Thus in most states in the U.S. a juror is not subject to arrest while serving in his official capacity or when proceeding to or returning from the place of service. The same is true of witnesses attending a place of trial in obedience to a subpoena. A judge is exempt while performing his official duties. Ordinarily a master is not subject to arrest for the tort of his servant unless he participated in his servant's wrong. While formerly a husband might be arrested for the tort of his wife, it is doubtful whether this result would follow under modern law. Various other exemptions are recognized in particular jurisdictions.

Apart from the cases of arrest relating to civil litigation discussed above, arrest of persons may also be authorized in connection with other specialized civil proceedings. Among the most important of these is the arrest of persons suffering from extreme mental disorder. The common-law principle, still generally recognized, is that any person may arrest one who is so insane as to constitute a danger to himself or others. Mental health legislation in many jurisdictions stipulates the conditions in which a mentally disturbed person may be seized and detained as a preliminary to proceedings leading to his commitment.

In English law on arrest there are certain features that require special mention. Not only is the person of the sovereign protected from arrest, but in civil suits no arrest can be carried out of any person of the sovereign's household "*bona fide,* substantially, and continually employed in waiting or attending on the royal person" unless the leave of the lord chamberlain has first been obtained. The same freedom from arrest, except upon a criminal charge, extends in principle to members of the house of lords and the house of commons. This immunity has been held to extend for members of the house of commons to a period 40 days before and 40 days after the sitting of parliament; while the house of lords claims privilege for its members whenever parliament is sitting. Each house claims to be informed whenever one of its members has been arrested or imprisoned upon a criminal charge. It is a question of some doubt whether the doctrine of diplomatic immunity extends so far as to protect ambassadors and diplomatic staff from arrest on a criminal charge.

It is one of the principles of English law on arrest that persons engaged on the business of the higher courts of justice shall be protected from arrest on civil process when about the business of the court, though just how far this privilege extends is not certain. Thus barristers enjoy immunity from arrest when on circuit or while going to or returning from the supreme court. The protection of officers of either house of parliament, as of witnesses, counsel or parliamentary agents who appear before either house or before a parliamentary committee, is an illustration of the same principle.

ARRESTMENT, in Scots law, the process by which a creditor detains the goods or effects of his debtor in the hands of third parties until the debt due to him is paid. It is divided into two kinds: (1) arrestment in security, used when proceedings are commencing, or in other circumstances where a claim may become, but is not yet, enforceable; and (2) arrestment in execution, following on the decree of a court, or on a registered document, under a clause or statutory power of registration, according to the custom of Scotland. By the process of arrestment the property covered is merely retained in place; to realize it for the satisfaction of the creditor's claim a further proceeding called "forthcoming" is necessary. By old practice, alimentary funds, *i.e.,* those necessary for subsistence, were not liable to arrestment. By the Wages Arrestment Limitation (Scotland) act, 1870, as amended by the Small Debt (Scotland) act, 1924, the wages of all labourers, farm servants, manufacturers, artificers and working people are not arrestable except (1) in so far as they exceed 35 s. per week; but the expense of the arrestment is not to be charged against the debtor unless the sum recovered exceeds the amount of the said expense; or (2) under decrees for alimentary allowances and payments or for rates and taxes imposed by law.

ARRHENIUS, SVANTE AUGUST (1859–1927), Swedish chemist, was one of the founders of the modern science of physical chemistry. He was born on Feb. 19, 1859, at the estate of Wijk near Uppsala. As a young child he showed an extraordinary facility in calculating, and at school distinguished himself by his mathematical ability. At the age of 17 he entered the University of Uppsala, devoting himself to physics in particular; but, finding that the practical instruction in physics there left something to be desired in those days, in 1881 he went to study under Erik Edlund at Stockholm.

In 1884 he took his doctor's degree at Uppsala with a thesis on galvanic conduction in electrolytes. This thesis, whose development later earned for Arrhenius the Nobel prize, was awarded the lowest "note" which could be granted without a definite refusal. It is divided into two parts, the first dealing with the experimental determination of the electrical conductivity of extremely dilute solutions, and the second with the theory of electrolytic conductivity. This second part expounds his theory of electrolytic dissociation and activity coefficients. It contains some ideas which later investigations have shown to require modification, but forms the foundation upon which all subsequent theories of conductivity of solutions have been built. The revolutionary nature of the theory, which required, for instance, that free sodium ions should exist in a solution of sodium chloride, prevented its being speedily

accepted, and it may be said that it was neglected rather than actively opposed.

Arrhenius himself put on record an anecdote which throws light on the attitude toward his views when they were new: "I came to my professor, Cleve, whom I admired very much, and I said, 'I have a new theory of electrical conductivity as a cause of chemical reactions.' He said, 'This is very interesting,' and then he said, 'Good-bye.' He explained to me later that he knew very well that there are so many different theories formed, and that they are almost all certain to be wrong, for after a short time they disappeared; and therefore, by using the statistical manner of forming his ideas, he concluded that my theory also would not exist long."

In 1887 he published a much revised, extended and consolidated version of his theory of electrolytic dissociation, entitled "Über die Dissociation der in Wasser gelösten Stoffe" in the *Zeitschrift für physikalische Chemie*, which had just been founded. Arrhenius' first thesis had won him the support of Wilhelm Ostwald (*q.v.*), in whose laboratory he worked in 1886, and in 1887 he likewise entered into an intimate friendship with Jacobus H. van't Hoff (*q.v.*). The theories of van't Hoff on osmotic pressure and of Ostwald on the affinity of acids accorded admirably with the views of Arrhenius, and these three friends fought together in unselfish alliance for the new doctrines, which ultimately won general acceptance. Arrhenius had a genius for friendship and in the 40 years between 1887 and his death met practically all the great men of science, and won their affection no less than their regard.

In 1891 Arrhenius declined a professorship at Giessen, Ger., and was appointed lecturer at the Stockholm university; in 1895 he was elected to a professorship in physics there. From 1887 to 1902 he also filled the office of rector of the university. During this time he was occupied in extending the application of the doctrine of electrolytic conductivity to a variety of problems of chemical action, and also, on the supposition that in certain conditions air conducts electrolytically, to the phenomena of atmospheric electricity. Many students from abroad as well as from Sweden worked under his direction. In 1900 he published *Lärobok i theoretik electrokemi* ("Treatise on Theoretical Electrochemistry"), which was translated into German and English, and *Lehrbuch der kosmischen Physik* ("Treatise on Cosmic Physics") appeared in 1903.

Arrhenius was a man of wide interests, and about this time he began to turn his attention to problems of the chemistry of living matter. In 1904 he delivered at the University of California a course of lectures designed to illustrate the applications of the methods of physical chemistry to explaining the reactions of toxins and antitoxins. These lectures were published in 1907 under the title *Immunochemistry*, and in 1915 he published further contributions to exact biochemistry under the title *Quantitative Laws in Biological Chemistry*, in which he again devoted much attention to toxins. He was also much occupied with problems of cosmogony. In his *Worlds in the Making* (1908), an English translation of *Das Werden der Welten* (1907), he combated the generally accepted doctrine that the universe is tending to what Rudolf Clausius termed *Wärmetod* (death of heat) through exhaustion of all sources of heat and motion, and suggested that by virtue of a mechanism which maintains its available energy it is self-renovating, energy being degraded in bodies which are in the solar state, but elevated or raised to a higher level in bodies which are in the nebular state. He further put forward the conception that life is universally diffused, constantly emitted from all habitable worlds in the form of spores which traverse space for years or ages, the majority being ultimately destroyed by the heat of some blazing star, but some few finding a resting place on bodies which have reached the habitable stage. He was one of the first to stress the important part which the pressure of light must play in cosmic physics, and pointed out that the repulsion of the tails of comets from the sun could be explained by this pressure. Astronomical problems, especially the question of the habitability of Mars, are discussed in his *Destinies of the Stars* (1918).

Arrhenius received universal recognition as one of the great men of his time when he was awarded the Nobel prize in 1903 for chemistry "in recognition of the special services rendered by him to the development of chemistry by his electrolytic theory of association." In 1905 after refusing a full professorship and private laboratory in Berlin, he was appointed director of the Nobel Institute for Physical Chemistry at Experimentalfältet, just outside Stockholm, a post which he held until a few months before his death on Oct. 2, 1927. He was buried in Uppsala. In 1910 he was made a foreign member of the Royal society, and in the course of his later career he received numerous honorary doctorates in both the old and new world, as well as the Davy medal of the Royal society and the Faraday medal of the Chemical society. A series of lectures, delivered at Yale university, New Haven, Conn., in 1911 is reproduced in *Theories of Solutions* (1912). He delighted both to visit his colleagues abroad and to receive his contemporaries and students at his home. A genial humour characterized his discourses and his private conversation, and he was welcome at scientific discussions in any land.

Besides the books mentioned above Arrhenius published, in 1926, *Erde und Weltall*, a combined and revised reissue of *Das Werden der Welten* and *Der Lebenslauf der Planeten*. A German translation of his original thesis on "Galvanic Conduction in Electrolytes" was published as no. 160 of *Ostwald's Klassiker* in 1907. The essence of this classic is given in English translation in no. 19 of the *Alembic Club Reprints* (1929).

ARRIAGA (Y BALZOLA), JUAN CRISÓSTOMO (JACOBO ANTONIO) (1806–1826), Spanish composer whose great promise was cut short by his early death. Born in Bilbao, Jan. 27, 1806, 50 years to the day after the birth of Mozart, he showed, like the earlier master, an extraordinary musical precocity; at the age of 13, without having received any lessons in harmony, he composed an opera, *Nada y mucho.* Its success when produced in Bilbao in 1820 led to his being sent to the Paris conservatoire, where he studied the violin under Pierre Baillot and harmony under F. J. Fétis. He matured with phenomenal rapidity, and within two years had written an eight-part fugal *Et vitam venturi*, which Cherubini declared a masterpiece; by the age of 18 he was an assistant professor at the conservatoire. Among his compositions, remarkable for freshness, originality, abundant invention and technical resource, are three string quartets which in style form a connective link between Haydn and Schubert (although the first contains one of Arriaga's rare suggestions of Spanish folk idiom), some French cantatas, a *Mass*, a *Salve Regina*, the opera *Los esclavos felices*, an octet for strings, trumpet, guitar and piano, and a symphony which, like most of his music, combines the classical tradition of Haydn and Mozart with a flavour of Rossini. Arriaga died in Paris on Jan. 17, 1826, and was buried in Montmartre cemetery. The chief theatre in his native Bilbao was later named after him.

See C. A. Figuerido, *El arte y la mente del músico J. C. de Arriaga* (1948). (L. Sa.)

ARRIAN (Flavius Arrianus) (*c.* 96–*c.* 180), Greek historian and philosopher, the most reliable source for the military career of Alexander the Great, was born in Nicomedia in Bithynia, about A.D. 96. He was greatly esteemed by Hadrian, who appointed him governor (*legatus*) of Cappadocia (131–137), where he distinguished himself in a campaign against the Alani. This is the only instance before the 3rd century in which a first-rate Roman military command was given to a Greek. Arrian spent much of his time at Athens, where he was archon during 147–148. In his declining years, he retired to his birthplace, where he devoted himself to literary work. He died about 180. His biography, by Dio Cassius, is lost.

When young, Arrian was the pupil and friend of the stoic philosopher Epictetus. He took verbatim notes of his teacher's lectures, which he subsequently published under the title of *The Dissertations* (*Diatribai*), in eight books, of which the first four are extant and constitute the chief authority for Stoic ethics, and *The Encheiridion* ("Manual") *of Epictetus*, a handbook of moral philosophy. The most important of Arrian's original works is his *Anabasis* ("Expedition") *of Alexander*, containing the history of Alexander the Great from his accession to his death. His chief authorities were, as he explains, Aristobulus of Cassandreia and Ptolemy, son of Lagus (afterward Ptolemy I of Egypt). Both were with Alexander in Asia, and Ptolemy especially, who became one of his leading generals, had access to the best information. It is due greatly to him that Arrian's is the most complete and trustworthy account of Alexander that has survived.

Other extant works of Arrian are: *Indica*, a description of India in the Ionic dialect, including the voyage of Nearchus, Alexander's general, from the Indus to the Persian gulf, which was intended as a supplement to the *Anabasis; Acies Contra Alanos* ("Campaign Against the Alani"), a fragment of importance for the knowledge of Roman military affairs; *Periplus of the Euxine* ("Voyage Around the Black Sea"), an official account written (131) for the emperor Hadrian; *Tactica*, attributed by some to Aelianus, who wrote in the reign of Trajan; *Cynegeticus* (Latin, *De venatione*), a treatise on the chase, supplementing that of Xenophon. The *Periplus of the Erythraean Sea* ("Voyage Around the Red Sea"), attributed to him, is by a later compiler. Among his lost works may be mentioned: *Ta meta Alexandron* ("Alexander's Successors"), a history of the period succeeding Alexander, of which a few pages survive, and an epitome is preserved in Photius; histories of Bithynia, the Alani and the Parthian wars under Trajan; the lives of Timoleon of Corinth, Dion of Syracuse and perhaps of a famous brigand named Tilliborus. The lost work *de rebus Physicis* probably belongs to him too, and not to another Arrian.

ARROL, SIR WILLIAM (1839–1913), British structural engineering contractor responsible for building the bridge across the Firth of Forth, Scot., was born at Houston, Renfrewshire, on Feb. 13, 1839. Apprenticed at 14 to a blacksmith in Paisley, he worked in various places until, in 1868, he opened his own boilerworks. In 1872 he started the Dalmarnock ironworks, which grew into a vast enterprise.

Arrol built many bridges for the Caledonian railway, including the Clyde viaduct at Glasgow, the second bridge across the river Tay and the Forth bridge, on the completion of which he was knighted. He also constructed the steelwork for Tower bridge, London, and the Nile bridge, Cairo. Knighted in 1890, he sat in parliament for South Ayrshire as a Unionist, 1892–1906. He died at Ayr on Feb. 20, 1913.

See Sir R. Purvis, *Sir William Arrol* (1913) and *Engineering, Lond.* (Feb. 21, 1913).
(S. B. Hn.)

ARRONDISSEMENT (from Fr. *arrondir*, "to make round"), a subdivision of the principal French administrative district, *département* (or department) (*q.v.*). The principal cities and their surrounding areas generally constitute the *arrondissements*. There are more than 300 *arrondissements* in metropolitan France, each containing usually from 100 to 150 towns. The administrative officer of the *arrondissement* containing the capital city of a *département* is the prefect; the other *arrondissements* are administered by subprefects. These officials are appointed by the national government. Most *arrondissements* are judicial as well as administrative districts. Before World War II the *arrondissements* had elected councils, but these were suspended in 1940. During most of the Third Republic the *arrondissement* was the basis of the electoral districts for the chamber of deputies.

The cities of Paris and Lyons are divided into local administrative units also called *arrondissements*, and some of France's naval regions are divided into *arrondissements maritimes;* neither of these should be confused with the departmental subdivisions of the same name. *See* also LOCAL GOVERNMENT. (Ry. P.)

ARROWHEAD, a common name for plants of the genus *Sagittaria*, a group of perennial aquatic or marsh herbs of the water plantain family (Alismaceae), so named because the leaves of the best-known species are characteristically arrow shaped. The scapes, which rise from tuberbearing or fleshy knotted rootstocks, are mostly erect though sometimes decumbent and more rarely floating. Though borne on partly submerged stalks, the strongly nerved leaves usually rise conspicuously above the water. The flowers, arranged in whorls of three at the top of the scapes, have three broad white petals alternating with three small green sepals; the fruit is a dense head of small achenes (dry, one-seeded). There are about 40 species, native to temperate and tropical regions, but chiefly American.

The common old world arrowhead (*S. sagittifolia*), found in ditches in England and Ireland, is very widely distributed in Europe and Asia. It grows three to four feet high and bears showy white flowers and orbicular achenes. Many profusely blooming and double-flowered varieties are cultivated in lily ponds and bog gardens. The similar broad-leaved arrowhead (*S. latifolia*), with sharply beaked achenes, grows in shallow water throughout North America except in the arctic region. Its large starchy tubers were used for food by the American Indians. In the lower San Joaquin and Sacramento valleys in California this arrowhead is known as tule potato, and is often cultivated for food by the Chinese of the district in a manner similar to the cultivation for its starchy tubers of *S. chinensis* (which by most botanists is reduced to the widespread *Sagittaria sagittifolia*) in China. The giant arrowhead (*S. montevidensis*) sometimes grows 6 ft. tall with leaf blades 2 ft. long, and bears showy white flowers from 2 in. to 3 in. across, blotched with brownish-purple at the base. This handsome species is native in South America from Peru and Chile to Brazil and Argentina, and was first introduced into cultivation in 1883 from seeds sent to England from Buenos Aires, Arg. It is now planted in water gardens in the warmer parts of the U.S. and has run wild in slow streams in California and the south Atlantic states.

ARROWROOT. A large proportion of the edible starches obtained from the rhizomes or rootstocks of various plants are known in commerce under the name of arrowroot. Properly the name should be restricted to the starch yielded by two or three species of *Maranta* (family Marantaceae), the chief of which is *M. arundinacea;* and when genuine or West Indian arrowroot is spoken of it is understood that this is the variety meant. *M. arundinacea* is probably a native of Guiana and western Brazil but it has long been cultivated in the West Indies and has spread to most tropical countries. The plant is a herbaceous perennial with a creeping rootstock which gives off fleshy cylindrical tubers, covered with pale brown or white scales and afterward ringed with their scars. When these tubers are gorged with starch, immediately before the season of rest, it is ripe for use. In addition to about 25% of starch, the tubers contain woody tissue, protein and salts. The arrowroot may be separated on a small scale by peeling

the root and grating it in water, when the starch falls to the bottom. The liquor is then drained off and the starch purified by repeated washings. On a large scale the manufacture of arrowroot is conducted with special machinery. Arrowroot is distinguished by the granules agglomerating into small balls, and by yielding with boiling water a fine, transparent odourless and pleasant-tasting jelly. In microscopic structure the granules are oval, marked with concentric lines, similar to potato starch, but having the hilum at the thick extremity of the granule instead of at the thin end. In addition to the West Indian supplies, arrowroot is cultivated in Brazil, southeast Asia, Australia and South Africa. The slender much-branched stem is 5 or 6 ft. high and bears numerous leaves with long narrow sheaths and large spreading ovate blades, and a few short-stalked white flowers.

ARROWROOT PLANT (MARANTA ARUNDINACEA)

(A) Upper part of flowering stem; (B) base of flowering stem and young branch of rhizome; (C) part of the mature rhizome

Tous-les-mois or Tulema arrowroot, also from the West Indies, is obtained from species of *Canna*, a genus allied to *Maranta* and cultivated in the same manner. The granules of tous-les-mois are very large. East India arrowroot is obtained from the rootstocks of species of *Curcuma* (family Zingiberaceae), chiefly *C. angustifolia*, a native of central India. Brazilian arrowroot is the starch of the cassava plant (*Manihot esculenta*), which when agglutinated on hot plates forms tapioca. Tacca or Otaheite arrowroot is the product of *Tacca pinnatifida*, the pia plant of the South Sea Islands. Portland arrowroot was formerly prepared on the Isle of Portland, England, from the tubers of the common cuckoo pint, *Arum maculatum*. Various other species of the arum yield valuable food starches in hot countries. Under the name of British arrowroot the farina of potatoes is sometimes sold. The chief use, however, of potato farina is for adulterating more costly preparations. This falsification can be detected by microscopic examination. Arrowroot contains about 82% starch and about 1% protein and mineral matter. *See* also STARCH.

ARROWSMITH, the name of a distinguished English family of geographers. The first, Aaron Arrowsmith (1750–1823), was born at Winston, Durham, on July 14, 1750. Without a formal education, he went to London, and after working as a surveyor, set up as a map maker and publisher. He became famous for his large chart of the world on Mercator's projection published in 1790. Four years later he published another large map of the world on the globular projection, with a companion volume of explanation. Another important work was his chart of the Pacific ocean in nine sheets (1798). His maps were clearly engraved and free from fanciful decoration. He died in London on April 23, 1823.

He left two sons, Aaron and Samuel, the elder of whom was the compiler of the *Eton Comparative Atlas*, of a biblical atlas, and of various manuals of geography. They carried on the business in company with John Arrowsmith (1790–1873), nephew of the elder Aaron. In 1834 John published his *London Atlas*, the best set of maps then in existence. He followed up the atlas with a long series of elaborate and carefully executed maps embodying the results of contemporary exploration, those of Australia, America, Africa and India being especially valuable. He was an original member of the Royal Geographical society and was awarded one of its gold medals. (G. R. CE.)

ARSACES, an Iranian name borne by the Parthian royal house as being descended from Arsaces, son of Phriapites (date unknown), a chief of the semi-nomadic Parni tribe from the Caspian steppes. The first of his line to gain power in Parthia was Arsaces I, brother of Tiridates, about 247 B.C. (the beginning of the Arsacid era). All Parthian kings after him used Arsaces as their throne name, and with the rare exceptions of usurpers and contestants for the throne, all are so designated on their coins and in official documents. By historians they are generally called by their personal names. The Arsacid dynasty maintained itself, although not in unbroken succession, until its overthrow by Ardashir (*q.v.*) in A.D. 224. During the time of the Parthian empire the Arsacids claimed descent from Artaxerxes II, probably to legitimate their rule over Achaemenian territories. By the Sasanian chroniclers they were linked either with the Achaemenids or with the Kayanians (patrons of Zoroaster); and the period of their rule was shortened to 266 years, because of faulty data and the requirements of Zoroastrian priestly chronology. From the Sasanian chronicles they enter Persian epic under the name the Ashkanian (individual rulers as Ashak, Ashkan).

The name Arsaces was also borne by several kings of Armenia (*q.v.*), who were of Parthian royal blood. It occurs also in cuneiform characters on a Persian seal, probably of the Parthian period. *See* PARTHIA; PERSIAN HISTORY. (MA. B.)

ARS ANTIQUA. The term was originally used in a polemical sense in a 14th-century treatise called *Ars Nova* by Philippe de Vitry to describe the "old technique" of composing from which he and the adherents of the "new style" had progressed. It was intended to refer to the late 13th-century style of writing motets. German musicologists adopted the term and gave it a wider meaning, using it to define the style of the whole polyphonic era, particularly in France, between 1230 and 1320. Further study of polyphonic music, however, revealed the great variety of forms and styles during that period, and the term "*ars antiqua*" reverted to its original meaning.

For bibliography, *see* ARS NOVA. (E. J. WZ.)

ARSENAL, a publicly owned establishment for the manufacture, repair or storage of munitions for land, sea or air forces. The term is used loosely to describe a variety of different types of establishments, including both storage depots and manufacturing plants, and during World War II was applied by Pres. F. D. Roosevelt to the whole United States when he used the phrase "arsenal of democracy." A closely related term, armory, is generally used in the United States to denote an establishment where weapons, usually small arms, are stored and kept ready for issue and where reserve troops assemble for training. But in some instances the term is applied to a manufacturing arsenal, meaning a place where armourers work.

In England the Tower of London served from the Plantagenet era down to the 17th century as a storehouse for weapons and as the official workshop for their manufacture. In modern times Woolwich arsenal has become the most famous British arsenal and since the early 1800s has been designated the royal arsenal. It began in the 17th century as a "gun wharf" on the Thames for the supply of naval vessels and later undertook the manufacture of bronze cannon and other munitions.

In the United States two arsenals, officially called armories, were established in the 1790s at Springfield, Mass., and Harpers Ferry, Va. (now W. Va.), to manufacture and store small arms and related supplies. They were to provide a dependable source of military weapons for the U.S. government and render it independent of other nations in this regard. During the early 1800s Frankford arsenal was established at Philadelphia, Watertown arsenal near Boston and Watervliet arsenal in upper New York state. At the same time, storage arsenals or depots were built at strategic points for the supply of the army, and gun factories were built for the navy. Rock Island arsenal was established in 1863 on an island in the Mississippi river, and later Picatinny arsenal in New Jersey was added as a powder factory. Of the U.S. manufacturing arsenals that continued in active service into the 20th century, each specialized in the development and manufacture of one or more classes of ordnance such as artillery, small arms or ammunition. Because of the great demand for armoured vehicles in World War II a new tank arsenal was created at Detroit, Mich.

After the war, Redstone arsenal in Alabama became the U.S. army's chief rocket and guided missile centre. (H. C. T.)

ARSENIC, a chemical element that has both gray and yellow crystalline forms. White arsenic (arsenious oxide), the common commercial form of the element, is usually prepared as a by-product of the roasting of various ores. The highly toxic nature of many arsenic compounds has led to their extensive use in insecticides and weed killers.

Arsenic is designated by the chemical symbol As. Its atomic number is 33 and its atomic weight is 74.9216.

History and Occurrence.—Of the compounds of arsenic, the sulfides are the earliest mentioned. In the 4th century B.C. Aristotle referred to a substance, probably realgar, which he designated as sandarach; Pedanios Dioscorides and Pliny the Elder in the 1st century refer to auripigmentum, which was probably orpiment. Both observed the change in colour and properties of the sulfide on calcining it. Albertus Magnus in the 13th century noted the appearance of a metallike substance on heating arsenicum (arsenious sulfide) with soap. Later writers considered arsenic to be a semimetal. In 1733 A. Brandt showed that white arsenic is an oxide of arsenic and in 1817 Jöns Jakob Berzelius established the weight relations of arsenic to the other elements.

Arsenic is widely distributed. It appears at low concentration in volcanic gas, sea water and spring water, and traces are present in many chemicals, metals and foodstuffs. Mineral deposits of native arsenic usually occur in metalliferous veins in association with ores of antimony, silver, etc. Some of the naturally occurring compounds of arsenic are shown in Table I. Of these, arsenopyrite or mispickel is the most abundant. (H. Te.)

Table I.—*Mineral Compounds of Arsenic*

Type	Mineral name	Formula
Oxide	arsenolite	As_2O_3
Metal oxyarsenic compounds	mimetite	$Pb_5Cl(AsO_4)_3$
	olivenite	Cu_2OHAsO_4
	scorodite	$FeAsO_4.2H_2O$
Arsenic sulfides	realgar	AsS
	orpiment	As_2S_3
Metal arsenides	smaltite	$CoAs_2$
	löllingite	$FeAs_2$
Metal-sulfarsenic compounds	arsenopyrite	$FeAsS$
	cobaltite	$CoAsS$
	tennantite	$Cu_3As_2S_7$
	enargite	Cu_3AsS_4
	proustite	Ag_3AsS_3

Production and Application.—White arsenic, As_2O_3, is the principal form of arsenic in commerce. The United States and Sweden are the leading producers, followed by Mexico, France, Germany, Italy and Japan.

Practically all of the white arsenic is produced as a by-product from the roasting of copper, lead, and other ores, although it can be produced by roasting arsenopyrite and arsenic sulfide ores. In general, arsenic is regarded as a troublesome impurity. The large amounts of arsenic oxide obtained as a by-product sometimes exceed the market demands, creating a disposal problem. At one time a Swedish plant placed its excess arsenic oxide in large concrete cylinders which were towed out and sunk in the ocean.

When ores containing arsenic are roasted the volatile oxide collects in the flue dusts. These dusts are roasted again and a crude product containing about 90% white arsenic is collected in condensing chambers. Refining of the crude oxide by volatilization yields a white crystalline product of over 99% white arsenic.

Metallic arsenic is produced by reducing arsenic trioxide with charcoal in a retort furnace of the horizontal type. The volatilized metallic arsenic is deposited on the walls of a water cooled condenser. Metallic arsenic was made in the United States during World War I and World War II, but in the early 1960s all needs were met by importations, mainly from Sweden.

The major uses of arsenic compounds are as insecticides, weed killers, in the manufacture of glass and in wood preservatives. The principal insecticides are lead arsenate, calcium arsenate, and Paris green (copper acetoarsenite); the use of arsenicals for this purpose has been reduced by the adoption of organic chemical compounds. Sodium arsenite is used as a weed killer; arsenic trioxide is used as a decolorizer in the glass industry; and sodium arsenate is used as a wood preservative.

The most important metallurgical use of arsenic is in arsenical copper, where it increases the corrosion and erosion resistance and raises the annealing temperature. Arsenical copper alloys are used in making automobile radiators and other objects assembled by soldering. Metallic arsenic is also added to lead for making shot in order to obtain more perfect spheres; in lead-tin-antimony-bearing alloys to obtain better strength at elevated temperatures; and as a partial replacement for antimony as a hardening agent in lead storage battery plates. (A. W. S.)

Physiological Effect and Therapeutic Uses.—The most common toxic forms of the arsenic compound are those of trivalent arsenic. The toxicity depends on the availability of the oxy-ions, and is greatly diminished if the solubility of the compound is low or if the arsenic is incorporated in other stable complexes. The principal effects produced by arsenic in the system are degeneration of the lining of the digestive tract and of the tissues of other internal organs, and probably also a direct attack on nerve tissue. Nausea, vomiting, diarrhea, headache, muscular pains, weak pulse and coma are symptoms observed in arsenic poisoning. (*See also* Poison: *Characteristics of Different Poisons: Irritant Poisons*).

Some inhabitants of Styria, Tyrol and other regions believe that arsenic compounds exert a tonic effect and the habit of arsenic eating is prevalent in these regions. Inorganic arsenic preparations have been prescribed for anemia, leukemia, nervous disorders, rheumatism, malaria, trypanosome infections and syphilis. Organic preparations are, however, less capricious and less dangerous and have supplanted inorganic compounds in many applications. For example, arsphenamine hydrochloride (salvarsan) and related derivatives have been used in the treatment of syphilis; and sodium arsanilate (atoxyl) has been used with success in the treatment of some forms of sleeping sickness.

CHEMISTRY OF ARSENIC AND ITS COMPOUNDS

Physical Properties and Structure of Elementary Arsenic.—Arsenic is placed in the main Group V of the periodic classification, below phosphorous and above antimony. The trend from nonmetallic to metallic characteristics as the atomic number in the group increases reveals itself in the appearance of metallic properties in some of the forms of elementary arsenic, but in terms of chemical properties, this element is best classified as a nonmetal. Some of the important properties of arsenic atoms are the following:

Electron configuration	$3s^2, 3p^6, 3d^{10}, 4s^2, 4p^3$
Ionizing potential of gaseous atom	10.5 v.
Radius of As^{+++} in crystals	0.69 Å
Mass numbers of isotopes	range from 68 to 80; only the natural isotope, 75, is stable.

Elementary arsenic exists at room temperature in two well-defined crystalline forms: metallic or gray arsenic, the common stable form, and yellow arsenic, which is unstable for all conditions with respect to transformation to other forms. Their physical properties are outlined in Table II.

Yellow arsenic is deposited when arsenic vapour is cooled suddenly below 0° C. It appears as well-formed crystals on evaporation of solvent from the solution in carbon disulfide. The transformation of yellow arsenic to stabler forms is accelerated by heat, by light and by certain substances, iodine and bromine being two which are thus catalytically active.

Other forms of elementary arsenic have been reported. If arsenic is sublimed, the characteristics of the deposits which appear depend on the temperature of deposition. At about 200° C., a black shiny deposit of density 4.7 g. per cubic centimeter collects. While the deposits at other temperatures differ in density and appearance, all are similar in that they are brittle, show conchoidal fracture, and none are obviously crystalline. Above about 280° C. only the gray form exists.

The crystal structure of elementary arsenic has been determined by X-ray methods. The crystals of the gray form are composed of double layers of atoms. Within a given double layer consisting of two planes of atoms, an atom of arsenic in one of the

TABLE II.—*Physical Properties of Arsenic*

Property	Gray arsenic	Yellow arsenic
Appearance	steel gray; opaque, metallic lustre	yellow; transparent
Crystalline system	hexagonal	cubic
Melting point	814° C. at 36 atm. press.	transforms below melting point
Specific heat	0.0772 at 28° C.	
Density	5.73 g./c.c.	2.03 g./c.c. at 18° C.
Electrical resistivity	35×10^{-6} ohm-cm./cm.^{3} at 20° C.	
Specific magnetic susceptibility	0.31×10^{-6}	
Linear coefficient of expansion	5.59×10^{-6} at 40° C.	
Cubic compressibility	4.5×10^{-6}/atm. at 20° C.	
Mechanical properties	brittle; hardness 3.5 on Mohs' scale	softer than gray form
Vapour pressure	1 atm. at 604° C.	more volatile than gray form
Heat of sublimation	580 kg.cal./g. atom	
Solubility	not appreciable in common solvents	8 g./100 c.c. CS_2 at 20° C.; slightly in C_6H_6 and glycerine

planes has as closest neighbours three equidistant atoms in the adjacent plane at a distance of 2.51 Å. The next closest neighbours are three equidistant atoms of an adjacent double layer, and are 3.15 Å removed. The yellow form of arsenic probably contains tetrahedrally shaped molecules As_4. This conclusion is reasonable since the molecular weight of yellow arsenic in carbon disulfide corresponds to the formula As_4, and in the analogous case of white phosphorus, the tetra-atomic molecules persist in the solid state.

Arsenic vapour at temperatures below 800° C. exists as As_4 molecules but at higher temperatures measurable decomposition into smaller molecules occurs. Thus, at 1,700° C. and ordinary pressure, the average molecular constitution of the gas corresponds to the formula As_2.

General Chemical Properties.—In common with the other main Group V elements, arsenic exhibits the range of valence states from 3− to 5+ in its compounds. These extremes, together with the 3+ state, embrace the principal compounds of the element. The enhanced electropositive character of arsenic as compared with phosphorus can be correlated with the following facts: AsH_3 is less stable than is PH_3, is a more powerful reducing agent and is less basic; the oxidation of As to the positive ion $As(OH)_2^+$ can be achieved by a weaker oxidizing agent than would be required for the corresponding hypothetical change with phosphorus; the hydroxide $As(OH)_3$, but not the hydroxide $P(OH)_3$, can be converted to a positive ion by strong acid. While the arsenic atom is larger than that of phosphorus, the usual co-ordination number to oxygen is still only four. The similarity in size and shape of arsenate and phosphate ions is indicated by the isomorphism of many metal arsenates and phosphates. In their chemical behaviour, however, phosphates and arsenates show important differences, the arsenates being in general much more labile. Thus, arsenates oxidize (*see* OXIDATION AND REDUCTION) much more rapidly than do phosphates, and equilibrium between *ortho* and condensed forms of arsenic acids is established much more rapidly than is the case with the phosphoric acids. Antimonates and arsenates are dissimilar in structure and in many properties, since the co-ordination number of antimony to oxygen in antimonates is six.

Analysis and Detection.—In a common scheme for qualitative analysis, arsenic is precipitated as the trisulfide, together with the sulfides of mercury, copper, antimony, tin, etc., by passing hydrogen sulfide into an acid solution containing these as ions. Iodide ion may be added to the solution to facilitate the reduction of arsenate, if present, to the 3+ valence state. Arsenious sulfide together with the sulfides of antimony and tin are separated from those of mercury, copper, etc., by treating the precipitates with an alkaline solution containing sulfide ion. In this operation, As_2S_3 is converted to AsS_2^-, and the antimony and tin sulfides to similar sulfo-anions. On making the resulting solution strongly acid, only arsenious sulfide precipitates. This can be filtered off and the presence of arsenic confirmed by a convenient one of the methods of detection described below.

Quantitative determination of arsenic can be based on the precipitation of magnesium ammonium arsenate. This solid is filtered off and dissolved in hydrochloric acid solution; the arsenic is then precipitated as As_2S_5, which is filtered off, washed, dried and weighed.

The detection of arsenic even in traces is important because of the toxic nature of many arsenic compounds. The Reinsch test utilizes the fact that arsenites in acid solution are reduced by copper. A piece of clean copper is inserted into the solution to be tested. If an arsenite is present a black deposit forms on the copper, and the deposit on heating in oxygen is converted to the white volatile oxide which collects on the walls of the tube. In other tests, the arsenite is reduced to the volatile substance arsine which is carried along by a stream of hydrogen. In the Fleitmann test, silver nitrate test paper is exposed to the vapour, a black deposit indicating the presence of arsine. In the Marsh test, the gas is passed through a heated tube, and if arsine is present, a shiny black mirror of arsenic is deposited. The similar mirror of antimony is not removed by a solution containing hypochlorite ion, but that of arsenic is. In the Gutzeit test, a mercuric chloride test paper is exposed to the gas stream, and develops a black stain if arsine is present. In each case, hydrogen sulfide is removed by generating the gas in an alkaline solution, or by passing it through a solution of lead acetate.

Chemical Properties of Elementary Arsenic.—Elementary arsenic can function both as an oxidizing agent and as a reducing agent. The half-reactions describing these modes of action, and their potentials relative to the normal hydrogen electrode as zero, are:

$$AsH_3 = As + 3H^+ + 3e^- \qquad E^\circ = 0.54$$
$$3H_2O + As = As(OH)_3\,aq. + 3H^+ + 3e^- \qquad E^\circ = -0.248$$

As is to be expected from the value of the potential for the reduction of elementary arsenic, only powerful reducing agents can accomplish this process. It does take place when arsenic is present at the cathode during electrolysis of an alkaline solution. A large variety of oxidizing agents oxidize elementary arsenic to higher valence states in the presence of water. Chlorine, bromine, concentrated nitric acid and potassium permanganate are examples.

In contrast to phosphorus, arsenic does not disproportionate to the 3+ and 3− valence states when it is treated with alkali. Fusion with alkali does result in the production of arsenite, but presumably hydroxide ion or oxygen functions as the oxidizing agent in the change.

In the dry state, arsenic can be oxidized by oxygen, fluorine, chlorine, bromine, iodine and sulfur as well as by other powerful oxidizing agents, such as KNO_3 or $KClO_3$. The products of interaction for the elementary oxidizing agents listed are: As_4O_6, AsF_3 or AsF_5, $AsCl_3$, $AsBr_3$, AsI_3 and As_2S_3 or As_2S_5. The changes take place readily in all cases, and in fact with O_2, F_2 and Cl_2 they can proceed as combustion reactions. Arsenic can be reduced in the dry state by the direct action of alkali metals and other active metals.

Valence State 3− and Compounds with Metals.—Arsine, AsH_3, is a colourless, extremely poisonous gas. The melting point and normal boiling point of the substance are −119° C. and −55° C. respectively. The solubility in water is low, much less than that of ammonia, but the solubility in less polar solvents such as fats and turpentine is quite high.

Arsine cannot be prepared by the direct combination of the elements. Two methods of preparation have been used: (1) the reduction of arsenious acid or arsenates by powerful reducing agents in a strongly acid or, for some metals, strongly alkaline medium, and (2) the interaction of water or a mineral acid with the arsenide of an active metal. The mineral acid commonly used is hydrochloric acid. Equations describing typical preparations are:

$$3Zn + 6H^+ + As(OH)_3 = 3Zn^{2+} + AsH_3 + 3H_2O$$
$$Zn_3As_2 + 6H^+ = 3Zn^{2+} + 2AsH_3$$

The second method of preparation yields a purer product.

Arsine is unstable with respect to decomposition into the constituent elements. This decomposition proceeds slowly under ordinary conditions but less rapidly if the gas is thoroughly dried

or if the surface area is decreased. The reaction is accelerated on the absorption of light and by an increase in temperature, and can proceed explosively if the gas is suitably detonated.

Arsine is a powerful reducing agent, being oxidized by even fairly weak oxidizing agents. It reduces soluble silver, mercury and gold salts, sulfurous acid and the more powerful oxidizing agents such as chromates, permanganates and the halogens. Arsine can act also as an oxidizing agent but only powerful reducing agents are affected; sodium and potassium react with it, reducing it to hydrogen and forming the corresponding arsenide.

Double decomposition reactions, involving the interaction of arsine with a metal salt to produce a metal arsenide and an acid, are not well defined. It seems likely that this type of change takes place when arsine is passed into a solution of a cupric salt, and the formation of a metal arsenide may be an intermediate stage in the net reduction by arsine of heavy metal ions.

The Compounds of Arsenic with Alkali, Alkaline Earth and several other metals are also examples of compounds containing arsenic in the 3− valence state. Specific examples are: Na_3As, Ca_3As_2, Zn_3As_2 and AlAs. Substances of this type can be prepared by the direct union of the elements or by heating the metals with arsenious oxide and carbon.

Other compounds of arsenic with metals, some of which are more complex than those of the previous class, are known. Many of these compounds occur naturally and some can be made by the methods used above. As the metals become increasingly noble, it is observed that the compounds depart more and more from the rather saltlike character of the alkali metal arsenides, and begin to assume metallic physical properties. The reaction with acid to form arsine does not take place for the more noble metal arsenic compounds and in these compounds the assignment of a negative valence state to arsenic has little significance.

The 3+ Valence State (in Solution).—Arsenic in the 3+ valence state can exist in water solution as a positive ion, as the hydroxide, as a negative oxy-ion and as a negative sulfarsenite ion.

A solution of the hydroxide, arsenious acid, is formed by bringing arsenious oxide in contact with water. The exact formula of the acid in water solution has not been established. However, it has been shown that the hydroxide contains only one arsenic atom per molecule and on this basis the formulation of the substance as $As(OH)_3$ or H_3AsO_3 seems reasonable. Arsenious acid is a weak monobasic acid; the value for the dissociation constant at 25° C. is about 6×10^{-10}.

There are a number of important association reactions involving the oxyarsenite species. Arsenious acid reacts with strong bases to give a solution containing the arsenite ion, $H_2AsO_3^-$. There is evidence that in solutions containing both arsenious acid and arsenite ion, substantial concentrations of a complex which has two arsenic atoms in each unit exists. Since most arsenites, with the exception of the alkali metal and ammonium arsenites are only sparingly soluble in water, precipitates are formed when solutions containing arsenites and many metal salts are mixed. The metal arsenites resulting are of various types. In some of the products, Ag_3AsO_3 and $Pb_3(AsO_3)_2$ for example, complete replacement of the hydrogen ions of the acid by metal ions has taken place. Other compounds, $Ca_3As_4O_9$ and $Ca_2As_2O_5$, for example, may contain polyarsenite ions. In some cases, association of metal and arsenite ions to form complex ions appears to take place. Thus, although copper arsenite is sparingly soluble in water, a precipitate does not form when a solution of a copper salt and an excess of an alkaline solution containing arsenite are at room temperature. In strongly acid solution, arsenious hydroxide is converted to a positive ion, which can be represented by the formula $As(OH)_2^+$. The constant governing the equilibrium, $As(OH)_3 = As(OH)_2^+ + OH^-$, is about 5×10^{-15}. When hydrogen sulfide is passed into a solution containing arsenious acid, arsenious sulfide is formed. If the concentration of ions in the solution is low, the sulfide persists for long periods of time as a colloidal suspension. In the presence of an electrolyte such as HCl, however, arsenious sulfide separates as a yellow precipitate.

Arsenious acid and arsenites are fairly strong and, in most cases, rapid reducing agents. Thus, chlorine, bromine and iodine, concentrated nitric acid, potassium permanganate, etc., rapidly transform arsenites to arsenates. With iodine, the oxidation is substantially complete only in neutral or alkaline solutions. In solutions of intermediate acidity, the equilibrium, $H_3AsO_4 + 2H^+ + 2I^- = As(OH)_3 + I_2 + H_2O$, is measurable.

The reduction of arsenites by powerful reducing agents has been discussed in connection with the chemistry of arsine.

A solution containing sulfarsenite ion can be prepared by dissolving arsenious sulfide in a solution containing sulfide ion. The sulfarsenite ion is commonly represented by the formula AsS_2^-. In the presence of acid the reaction, $2AsS_2^- + 2H^+ \rightarrow As_2S_3 + H_2S$, takes place.

Many metal sulfarsenites, of formulas analogous to arsenites, are formed on adding soluble metal salts to solutions of sulfarsenites. Examples are $Ba_3(AsS_3)_2$ and $Ba_2As_2S_5$.

Compounds in the 3+ Valence State.—*Arsenious oxide*, As_2O_3, the substance referred to as white arsenic and often simply as arsenic, exists in several forms as shown in Table III.

TABLE III.—*Physical Properties of Arsenious Oxide*

Property	Arsenolite	Claudetite	Amorphous
Crystalline system	cubic	monoclinic	amorphous
Colour	white	white	colourless
Density, g./c.c.	3.65 at 12.5° C.	4.05	3.68 at 12.5° C.
Melting point	275° C.	*c.* 315° C.	*c.* 200° C.
Solubility, g./100 g H_2O	2.04 at 25° C.		*c.* 4 at 13° C.
Vapour pressure	6 mm. at 240° C.	6 mm. at 240° C	
Hardness	1.5	2.5	

Cubic white arsenic is the common form. The so-called amorphous variety is unstable with respect to the other forms at room temperature and changes over fairly rapidly to the cubic form in the presence of water. It is formed on slow condensation of arsenious oxide vapour.

In the vapour state arsenious oxide exists as molecules As_4O_6 up to temperatures well in excess of 1,000° C. At sufficiently high temperature, dissociation to smaller molecules does take place. In solution in nitrobenzene the substance also exists as As_4O_6 molecules, and X-ray studies have shown As_4O_6 molecules to be present in the cubic modification. As_4O_6 molecules have arsenic atoms in a tetrahedral configuration, with oxygen atoms bridging them along the tetrahedron edges. The As—O separation is 1.80±0.02Å, the As—O—As angle is 126±3° and the O—As—O angle is 100±1.5°.

The reactions of arsenious oxide in water are included in the chemistry of arsenious acid. It is of interest to note that the rate of solution of arsenious oxide in water is accelerated by mineral acid, presumably because As—O bonds must be hydrolyzed in the process.

Arsenious Halides.—The halides can be formed by direct union of the elements or by treating arsenious acid with the corresponding hydrogen halide. With the latter method of preparation, the fluorine, chlorine and bromine compounds can be distilled off from the reaction mixtures while the iodine compound separates as crystals.

TABLE IV.—*Physical Properties of Arsenious Halides*

Property	AsF_3	$AsCl_3$	$AsBr_3$	AsI_3
Colour	colourless	colourless	colourless	red
Melting point	−8.5° C.	−18° C.	31° C.	146° C.
Boiling point	64° C.	130° C.	221° C.	*c.* 400° C
Density, g./c.c.	2.67 at 0° C.	2.18 at 20° C.	3.66 at 15° C	4.39 at 15° C
Dielectric constant		12.4 at 21° C.	8.33 at 35° C.	7.0 at 150° C
Heat of formation		71.4 kg cal.	45.6 kg.cal.	13.5 kg cal
Molecular shape	pyramidal	pyramidal	pyramidal	pyramidal
As X distance	1.72 Å	2.16 Å	2.31 Å	2.51 Å
X-As-X angle		103 ± 3°	101.5°	102.5°

As may be seen from their physical properties, and the observation that the dissociation in the liquid state or in solvents is very slight, the arsenic halides are not saltlike. In water solution they are rapidly hydrolyzed to arsenious acid and the hydrogen

halide.

Arsenious sulfide occurs naturally as orpiment. It can be made by heating arsenic and sulfur in equivalent amounts. An amorphous, or cryptocrystalline, form is deposited when hydrogen sulfide and arsenious acid interact in water solution.

The solubility of arsenious sulfide in water is very low. Even concentrated hydrochloric acid, if cold, does not affect it, but it is transformed by sulfide ion to sulfarsenite ion, by concentrated alkali to sulfarsenite and arsenite ion and by oxidizing agents to arsenates and sulfur.

The Valence State 5+ (in Solution).—The principal forms to consider for the 5+ valence state in water solution are arsenic acid, its ions and the sulfarsenate ion. Only the *ortho* form of arsenic acid exists in water solution in reasonable concentrations.

Arsenic acid functions as a tribasic acid. The dissociation constants for the successive dissociations are 4.8×10^{-3}, 4.8×10^{-7} and 4.8×10^{-13}. Most arsenate salts except ammonium and alkali metal salts are only sparingly soluble in water, and can be precipitated by mixing solutions of arsenates and the appropriate metal salts. The products obtained from water solution are almost always the *ortho*-arsenates.

Arsenic acid is a sufficiently powerful oxidizing agent to oxidize stannous salts, iodides in acid solution and sulfurous acid. The reaction with hydrogen sulfide can proceed either as the double decomposition reaction, $2H_3AsO_4+5H_2S=As_2S_5+8H_2O$, or as the oxidation-reduction reaction, $2H_3AsO_4+5H_2S=As_2S_3+2S+8H_2O$. Both changes proceed slowly but are accelerated by an increase in hydrogen ion concentration and of temperature. An increase in concentration of arsenic acid favours its reduction relative to precipitation of arsenic pentasulfide.

Sulfarsenate ion in solution is represented by the formula AsS_4^{3-}. It is formed when arsenic pentasulfide is treated with a solution containing sulfide ion, or arsenious sulfide with polysulfide ion. The acid corresponding to the ion is unstable and decomposes to arsenious sulfide and hydrogen sulfide. As a class the sulfarsenates are more soluble than the arsenates but precipitates of heavy metal sulfarsenates can be formed from water solutions. *Ortho*-sulfarsenates, $Cu_3(AsS_4)_2$, etc., and *pyro*-sulfarsenates, $Co_2As_2S_7$, etc., are known.

Compounds in the 5+ Valence State.—When a solution of arsenic acid, made for example by oxidizing arsenious oxide with concentrated nitric acid, is evaporated, the solid hydrate $2H_3AsO_4.H_2O$ separates. On further dehydration, crystals of *pyro*-arsenic acid $H_4As_2O_7$ are formed. Continued heating produces a glassy mass of simplest formula $HAsO_3$ and on complete dehydration arsenic pentoxide, of simplest formula As_2O_5, results.

Arsenic pentoxide formed on the dehydration is white and appears noncrystalline on examination under a microscope. At a sufficiently high temperature it melts and on cooling forms a glassy solid. In the vapour state at high temperature it dissociates to arsenious oxide and oxygen. As_2O_5, $HAsO_3$ and $H_4As_2O_7$ all absorb water rapidly and are transformed to *ortho*-arsenic acid.

Arsenic pentafluoride has been prepared by the spontaneous interaction of arsenic trifluoride and fluorine, and by heating a mixture of arsenic trifluoride, antimony pentafluoride and bromine. The boiling point of arsenic pentafluoride is $-53°$ C. and its melting point $-80°$ C. It has been suggested that arsenic pentachloride is formed when arsenic trichloride and chlorine react at low temperature. The substance if it exists is unstable above $-30°$ C.

Arsenic pentasulfide, As_2S_5, can be prepared by heating the elements in the proportions required by the formula. It is yellow in colour, and only sparingly soluble in water. At high temperatures, it decomposes to arsenious sulfide and sulfur.

Organic Derivatives of Arsenic.—Most of the organic derivatives of arsenic can be considered in two series:

Series I, R_3As, R_2AsX, $RAsX_2$, AsX_3
Series II, R_3AsX_2, R_2AsX_3, $RAsX_4$, AsX_5

In the general formulas above, R represents hydrogen atoms and aliphatic or aromatic organic radicals and X represents an electronegative atom or radical (F, Cl, Br, I, OH, $\frac{1}{2}SO_4$, etc.). The least oxidized members of each series appear at the left in each list, the increasingly more oxidized members to the right arising by progressive replacement of organic radicals by electronegative atoms or radicals. Arsenious and arsenic acids are examples of the most oxidized members for series I and II, respectively.

Series I.—In the lowest stage of oxidation for the first series, compounds of the type RH_2As, R_2HAs and R_3As are known. None of the substances in the class above has pronounced basic character to H^+, although they do show a strong affinity for some metal ions such as Pt(II), Pd(II). Arsenic trimethyl, $(CH_3)_3As$ can be prepared by the reaction of arsenic trichloride with zinc dimethyl. By the action of an alkyl iodide on compounds of the type R_3As, tetra-alkylarsonium compounds are formed. The tetra-alkylarsonium compounds such as R_4AsCl are saltlike, little hydrolyzed and are completely dissociated into ions in water. R_4AsOH is a strong base.

In the second stage of oxidation, the cacodyl derivatives, $(CH_3)_2As—X$, have received particular attention. Cacodyl oxide, $(CH_3)_2As—O—As(CH_3)_2$, is prepared by distilling a mixture of potassium acetate and arsenious acid. On treatment of cacodyl oxide with HCl, cacodyl chloride, $(CH_3)_2AsCl$, is obtained. The halogen is readily replaced by other electronegative groups. By reduction of cacodyl oxide, free cacodyl, $(CH_3)_2As—As(CH_3)_2$, analogous to hydrazine in structure, is formed.

In the third stage of oxidation, RAsO rather than $RAs(OH)_2$ is formed when a substance of the type $RAsCl_2$ is treated with a base. Compounds of the type $RAsCl_2$ can be prepared by the action of chlorine on $RAsH_2$.

Examples of organic derivatives of the final stage of oxidation in the first series are esters of arsenous acid. The ester $As(OC_2H_5)_3$ is prepared by the reaction of arsenic trichloride and ethyl alcohol.

Series II.—Trimethyl arsine oxide, $(CH_3)_3AsO$, an example of the lowest oxidation state for the second series of arsenic organic derivatives, results when $(CH_3)_3As$ is exposed to air. Compounds of the type R_3AsCl_2 can be prepared by treating R_3As with chlorine.

An important compound in the second stage of oxidation for the second series is dimethyl arsenic (or cacodylic) acid, $(CH_3)_2AsO$ OH. It can be obtained by oxidizing cacodylic oxide with mercuric oxide in the presence of water. It is a weaker acid than is arsenic acid, its dissociation constant being 6.4×10^{-7}.

Methyl arsinic acid, $CH_3AsO(OH)_2$, is a representative of the third stage of oxidation. Sodium methyl arsenate is formed when sodium arsenite and methyl iodide are left in contact in dilute alcoholic solution for several days.

In addition to the organic compounds described thus far, there are others in which As—As bonds are retained. They include cacodyl, mentioned above, arsenobenzene ($C_6H_5As—AsC_6H_5$) and its derivatives, and arsenomethane $(CH_3As)_n$.

The latter two present interesting structural features; arsenobenzene because a multiple As—As bond is presumably involved, and arsenomethane because of the problem of the skeletal arrangement.

ARSENIUS AUTORIANUS (d. A.D. 1273), patriarch of Constantinople, whose deposition caused a schism in the Byzantine Church, was born in Constantinople. Baptized George, he took the name Gennadius on becoming a monk and Arsenius on being appointed patriarch in 1255 by Theodore II Lascaris, to whose son John IV Lascaris he later became guardian. Arsenius retired to a monastery when Michael VIII Palaeologus usurped the throne from John IV, but was persuaded to return to office after Constantinople had been won back from the Latins in 1261. When Michael blinded John, Arsenius excommunicated him and

as a result was deposed (1265). He died in exile on Proconnesus (Marmora) in 1273.

Arsenius wrote a testament that is an important document for contemporary history, and he may be the author of an anacreontic poem on Easter. He did not write the three Kanons that have been ascribed to him but are the work of another Arsenius. Similarly he is not the author of the *Synopsis canonum* extant under the name Arsenius. After Arsenius' deposition the empire was split into two factions known as the Arsenites and the Josephists (called after Joseph, Arsenius' second successor). The Zealot party took the side of the Arsenites, who strongly opposed the pro-Latin policy of the emperor, which culminated in the Council of Lyons (1274), when papal supremacy was accepted by the Byzantine legates. The Arsenite schism, which continued after this decision had been rejected by the Byzantine people and officially abandoned as imperial policy, was not healed until 1310 when the body of Arsenius was buried in Hagia Sophia by the patriarch Niphon.

Laurent "L'Excommunication du patriarche Joseph 1er par son prédécesseur Arsène" in *Byzantinische Zeitschrift*, vol. xxx, pp. 489–496 (1929 30).

ARSENOPYRITE, a mineral consisting of iron sulfarsenide, contains 46% of arsenic and is of importance as an ore of this element. The mineral was known to Georgius Agricola, the "father of mineralogy," in 1546 under the name *mistpuckel* (Eng., mispickel).

Arsenopyrite is the most abundant and widespread arsenic mineral. It occurs with ores of tin, copper, gold, etc., in metalliferous veins and contact metamorphic sulfide deposits. It is also found, sparingly disseminated, in pegmatites, crystalline limestones and schists. Arsenopyrite is the principal source of arsenious acid, the "white arsenic" of commerce (*see* Arsenic). The chief supplies are from Boliden in Sweden, the United States and Mexico. Finely crystallized specimens have been obtained at Freiberg and Munzig, Ger.; Mitterberg near Mühlbach, Aus.; and Reichenstein, Silesia.

The crystals are monoclinic. They are often prismatic in habit and are usually terminated by faces of an obtuse dome. The colour is silver white to steel gray, with a metallic lustre; the streak is grayish black. The hardness is 5.5 to 6, and the specific gravity 6.1.

Arsenopyrite generally is formed at relatively high temperatures. Some varieties of the mineral contain cobalt in solid solution, and a series exists from arsenopyrite, FeAsS, to the mineral glaucodot, (Co,Fe)AsS. (Cl. F.)

ARSES, king of Persia, the youngest son of Artaxerxes III, was raised to the throne in 338 B.C. by Bagoas (*q.v.*), who had murdered Arses' father and all his brothers.

But when the young king tried to make himself independent, Bagoas killed him too, with all his children, in the third year of his reign (336 B.C.).

ARSINOE, the name of four queens of the Ptolemaic dynasty in Egypt (*see* Ptolemies). The name was also that of the mother of Ptolemy I, founder of the dynasty. The queens are listed below.

Arsinoe (I) (fl. early 3rd century B.C.), daughter of Lysimachus, king of Thrace, was the first wife of Ptolemy II, whom she married not later than 281 B.C. and to whom she bore three children, the future king Ptolemy III, Lysimachus and Berenice. About 278, accused of having conspired with two courtiers against her husband's life, she was banished to Coptos in upper Egypt. The truth of the charge is doubtful; possibly she was a victim of the intrigues of Arsinoe (II), her sister-in-law and stepmother.

Arsinoe (II) (*c.* 316–270 B.C.), daughter of Ptolemy I and Berenice, married Lysimachus, king of Thrace, as his third wife *c.* 298. Energetic, ambitious and ruthless, she gained much influence with her aged husband, who renamed Ephesus after her and delivered to her as personal domains Heraclea, Tios, Amastris (all on the Black sea) and Cassandria (in Chalcidice). She bore him three sons, Ptolemaeus, Lysimachus and Philip. To assist their prospects she is said to have persuaded Lysimachus to execute his eldest son and heir, Agathocles, on a false charge of treason. This caused opinion to move in favour of Seleucus, who then invaded the territory of Lysimachus in Asia Minor. When Lysimachus was defeated and killed at Corupedium in Lydia (281), Arsinoe escaped from Ephesus to Cassandria. Her half-brother Ptolemy Ceraunus murdered Seleucus and took possession of Thrace and Macedonia; he then tricked Arsinoe into marrying him, seized Cassandria and murdered her two younger sons. The eldest escaped; so too did Arsinoe, first to Samothrace, then to Egypt (279). Some time after her arrival there she married her full brother Ptolemy II, so displacing Arsinoe (I). This marriage of brother and sister corresponded to Egyptian custom but was an innovation for Greek rulers.

Arsinoe now exercised an even greater influence in state affairs than she had done in Lysimachus' kingdom, and many of Egypt's military and political successes in the following years were due to her. She was in the fullest sense a co-ruler: her head figured on the coinage, either alone or with the king's; she wore the diadem; in the native ritual she possessed a throne name (not customary in the case of a queen); and even before her death (270) she was the object of a widespread cult both in Egypt and overseas. The Greeks worshiped her as Thea Philadelphos ("goddess who loves her brother"). In several instances her cult takes precedence over her husband's—a further proof that she was the dominant partner. No other queen in the Hellenistic world received so many honours; a number of cities in Lycia, Cilicia, Aetolia, Libya, Syria, Cyprus and Egypt took her name, either before or after her death, and many dedications to her are found in the Aegean area, in Cyprus and in Egypt itself. After death her memory was kept alive; an Athenian inscription praises Ptolemy for following his dead wife's policy; in Egypt a great shrine, the Arsinoeion, was consecrated at Alexandria and a colossal obelisk of granite erected there; and similar memorials were consecrated in other parts of Egypt and at Samothrace. She became the guardian goddess of the province lying about Lake Moeris in the Faiyum (upper Egypt), known henceforth as the Arsinoite nome.

Arsinoe (III) (late 3rd century B.C.), daughter of Ptolemy III and Berenice, married her full brother Ptolemy IV Philopator and was present with him at the battle of Raphia (Rafa on the frontier of Egypt and Palestine) in 217 B.C., where she gave encouragement to the troops. Her marriage to the king probably took place after the battle. In 210 she gave birth to the future Ptolemy V. Her efforts to detach her husband from debauchery were unavailing and she was eventually killed by the courtiers Sosibius and Philammon. This crime, of uncertain date, first became known with the news of the king's own death, which was also kept secret until late in 203. The queen had been held in high esteem by her subjects, and the news of her death and the suspicion of foul play led to an outbreak in Alexandria against the assassins.

Arsinoe (IV) (d. 41 B.C.), youngest daughter of Ptolemy Auletes, was the younger sister of the famous Cleopatra. At the outset of the Alexandrine War (48–47 B.C.) she was for a time recognized as queen by the Alexandrian populace. Captured at the end of the war, she was sent to Rome to appear in Julius Caesar's triumph (46). Subsequently she was set free and returned to the east, but in 41, at Cleopatra's instigation, Antony put her to death.

See G. H. Macurdy, *Hellenistic Queens* (1932). (R. H. St.)

ARS NOVA, the title of a musical treatise by Philippe de Vitry (1291–1361), written in 1320, probably in Paris, outlining the technical innovations used by Vitry, particularly the introduction of more accidentals and duple rhythms, which were indicated by notes in red ink. The new style may already have been in use in southern France and Italy, since a bull of Pope John XXII, dated 1324–25 from Avignon, condemns the mannerisms of "the pupils of a new school." The treatise reflects the struggle between an older and younger generation of composers, which ended *c.* 1330. By that time the achievements of those using the new techniques were generally recognized. Recent musicologists have used the term "Ars Nova" in a wider sense for a period opposed to the preceding "Ars Antiqua" (*q.v.*) and covering the work of Vitry and Guillaume de Machaut (*q.v.*), that is, the

greater part of the 14th century.

III in the "New Oxford History of Music Series" (1960); L. Schrade, "The Chronology of the Ars Nova in France," in *Compte rendu du Colloque International d'Ars Nova* (1959).

(E. J. Wz.)

ARSON, a common-law crime defined as the malicious and voluntary burning of the dwelling house of another, has in modern times, both in England and the United States, been greatly expanded in scope by statute Common-law arson is often termed a "crime against the habitation" rather than a "crime against property" in recognition of the fact that its prohibition is aimed more at protecting people from the danger of injury or death by fire than at protecting their property from damage. Modern arson statutes encompass the latter aim as well.

Common-Law Arson.—At common law, arson, a felony originally punishable by death, consists of four separate elements, three physical, the fourth mental: (1) "Burning": The house need not be entirely, or even in large part, consumed by fire; the burning of any small portion of the house, such as a part of the floor or wall or door, is enough. But, though the wood of the house need not be set ablaze, there must be a charring, the destruction of the fibre of the wood; a mere discoloration will not suffice. (2) "Dwelling house": A building is a dwelling house if people customarily sleep there, though it is not necessary that someone actually be in the house at the time of the fire. An abandoned dwelling is no longer a dwelling house, but a house is still a dwelling house though the inhabitants close it for the summer, intending to return. Weekend cabins, modern trailers, buildings used partly for living and partly for business (as a building with a store on the first floor, living quarters on the second floor) have all been held to be dwelling houses. On the other hand, unfinished structures, designed for dwelling purposes but not yet occupied, are generally held not to be dwelling houses. In England common-law arson encompasses the burning of outbuildings, such as barns and stables, which are part and parcel of the dwelling house because they are "within the curtilage" of the house, *i.e.*, enclosed within a common wall, hedge or fence. In more spacious America, where such enclosures are less common, outbuildings have been included for arson purposes, though not so enclosed, where the building is used in connection with the house and not situated too far away. (3) "Of another". At common law it is not arson to burn one's own house (*e.g.*, to defraud the insurance company). (It is a common-law misdemeanour—not the felony of arson—intentionally to burn one's own house where other houses are close by; but if in fact another house is thereby burned, such conduct constitutes arson.) The term "of another," however, refers to the right to possession rather than to ownership. Thus a landlord is guilty of arson who burns the house he has leased to his tenant; but a tenant is not guilty of arson who burns the leased premises. The owner of a house who leases a part of it to a tenant is guilty of arson, however, if he sets his house afire. (4) "Malicious and voluntary": The act of burning another's dwelling house, to constitute arson, must be accompanied by a "malicious and voluntary" state of mind. "Malice" in the literal sense of hatred, spite or ill will is not required. An intention to burn the building, unaccompanied by any such hatred, will suffice. It is probably true also that a reckless burning (*i.e.*, conduct which the actor realizes creates a high degree of risk of causing a burning, though he does not desire it) will do for arson, though mere negligence or accident clearly will not suffice. Probably criminal conduct which causes an unintended and nonreckless burning—as where a candlelight burglar in the course of the burglary carelessly leaves his candle too close to the curtains, thus causing the burglarized house to burn—will not qualify for arson.

Statutory Arson.—Modern statutes, in England and the United States, have enlarged the scope of arson by altering two of its four common-law elements. First, other types of property, other than dwelling houses, have commonly been made the subject of arson: unfinished dwellings, various types of buildings other than dwellings (*e.g.*, stores, warehouses, factories, churches), automobiles, railroad cars, ships, bridges, fences, trees and stacks of hay or grain. Second, it is commonly made arson for one to burn his own property, real or personal, if done to defraud the insurance company. (But modern statutes generally still require a "burning" in the sense of charring, rather than mere discoloration, and "malicious and voluntary" burning in the sense of intentional and perhaps reckless burning, rather than merely negligent or accidental burning.) Generally accompanying these new additions to arson has been a division of arson into two or more degrees, with heavier punishments assigned to what was common-law arson, with its emphasis on danger to human life, and lighter punishments to the new types of statutory arson, which involve primarily a danger to property.

Insanity as a Defense.—Criminal insanity in the generally accepted sense of mental disease which prevents knowing right from wrong constitutes a defense to arson as to other crimes. About 15 of the states of the United States accept the "irresistible impulse" test for insanity in addition to the "right and wrong" test; in such states pyromania (a mental disease causing the sufferer to possess an irresistible urge to set fires) affords a defense to arson, though the pyromaniac should be held for psychiatric treatment of his dangerous disease before being released.

Motives for Arson.—The principal motives for intentionally burning property are (1) to collect fire insurance; (2) to conceal the existence of some other crime (as where a murderer burns the building containing the corpse to conceal the fact of murder); (3) to obtain revenge upon the owner; (4) to punish the owner, generally a merchant, for failure to pay demanded extortion money; and (5) to experience the excitement of watching the blaze. Motive, as distinguished from intent, is generally irrelevant to guilt or innocence of crime; but in statutory arson to defraud the insurance company the particular motive to defraud is required; and in states which accept the "irresistible impulse" test of insanity, the existence of pyromania constitutes a defense.

Arson-Murder.—An arson which actually produces a death—as where the fire kills the occupant of the burned dwelling house or a fireman fighting the blaze—constitutes common-law murder, and generally statutory murder, even though the arsonist does not intend to kill anyone, at least where the death is the foreseeable consequence of the arsonist's act of setting the fire. England abolished this form of "constructive" murder in 1957.

See also CRIMINAL LAW. (A. W. ST.)

ARSUF, an ancient town on the coast of Palestine, situated 9 mi. N.N.E. of the modern Tel Aviv in Israel and famous for the victory won there in 1191 by the English king Richard I during the third crusade (*see* CRUSADES). Richard, having taken Acre in July 1191, was marching on Joppa (Jaffa) in preparation for an attack on Jerusalem, but the Muslim army under Saladin slowed down the crusaders' progress when they advanced from Caesarea, which they left on Sept. 1. Richard marched his forces in strict formation, dividing the cavalry into three bodies, which advanced with the infantry protecting their flanks. On Sept. 7, after the crusaders had left Arsuf, the Muslim attacks became more intensive and were concentrated against the Hospitallers, Richard's rearguard, whom Richard forbade to counterattack until the evening. He then ordered the infantry to open ranks and launched a general charge that overwhelmed Saladin's army and inflicted heavy losses on the forces attacking to the rear. Seven hundred crusaders and several thousand Muslims were killed.

The victory at Arsuf enabled the crusaders to occupy Joppa but was not a crushing blow to the Muslims, as has been asserted. Saladin was able to regroup his forces, which the crusaders had not pursued for fear of ambushes. From Sept. 9 onward the Muslims renewed their harassing tactics and Richard did not dare to push on to Jerusalem.

ART (ARTICLES ON). In this article, art is taken to mean the visual, plastic, and graphic arts. For articles on the other arts, *see* articles such as MUSIC (ARTICLES ON); LITERATURE (ARTICLES ON); THEATRE (ARTICLES ON).

The artist may attempt to communicate a sense of beauty or he

may react to his impulses and attempt to express them in various mediums; finally, he may accept a commission for a specific work and execute it to the best of his capability. These basic attitudes are discussed in ART, which includes a review of the history of art and a discussion of trends in art in terms of western and oriental approaches. Attempts to define the nature of beauty and to fit the concept into a philosophical and psychological framework are described in AESTHETICS and AESTHETICS, HISTORY OF.

Articles in which the history of European art is summarized along general lines include (in approximately chronological order): GREEK ART; ROMAN ART; EARLY CHRISTIAN ART; BYZANTINE ART; ROMANESQUE ART; GOTHIC ART; RENAISSANCE ART; BAROQUE ART; NEOCLASSICAL ART; NINETEENTH-CENTURY ART; MODERN ART. These articles are supplemented by others on distinctive phases, as: ABSTRACT ART; BARBIZON SCHOOL; EXPRESSIONISM; FAUVISM; FUTURISM; IMPRESSIONISM; POSTIMPRESSIONISM; SURREALISM. Also, there are articles on DESIGN, 19TH-CENTURY; and DESIGN, 20TH-CENTURY.

Articles on the characteristic art of various regions include: ARMENIAN ART; CHINESE PAINTING; INDIAN ART; INDONESIAN ARCHAEOLOGY AND ART; ISLAMIC ART; JAPANESE PAINTING AND PRINTS; PERSIAN ART; RUSSIAN ART; TIBETAN ART; etc.

The rise of the great European schools of painting under the influence of Christianity and their evolution in various countries is described in PAINTING, which is accompanied by many illustrative plates. The major types of subject matter are treated in STILL-LIFE PAINTING; PORTRAIT PAINTING; and LANDSCAPE PAINTING. Articles devoted to painting mediums include ENCAUSTIC PAINTING; GOUACHE; OIL PAINTING, TECHNIQUE OF; PASTEL; TEMPERA; and WATER-COLOUR PAINTING.

Articles dealing with engraving processes include DRY POINT; ETCHING; ENGRAVING, LINE; LITHOGRAPH; MEZZOTINT; STIPPLE AND CRAYON ENGRAVING; and WOODCUT AND WOOD ENGRAVING.

Various technical procedures in the arts are discussed in many other articles, for example: CRAYON DRAWING; DESIGN; DRAWING (TECHNIQUES OF); MINIATURE PAINTING; MURAL PAINTING; PENCIL DRAWING; PEN DRAWING; PERSPECTIVE; and POSTER.

Certain themes in the tradition of art are traced in DANCE OF DEATH; CARICATURE AND CARTOON; MOTION PICTURES (including animated cartoons).

SCULPTURE surveys the history of this art in western civilization in postclassical times; it is supplemented by SCULPTURE TECHNIQUES. Greek sculpture is discussed in GREEK ART, Roman sculpture in ROMAN ART. Separate articles are devoted to CHINESE SCULPTURE and JAPANESE SCULPTURE. Articles on special phases include SCULPTURE, SEPULCHRAL; IVORY CARVING; JADE AND OTHER HARD STONE CARVINGS; RELIEF; TERRA COTTA; WOOD CARVING; WAX FIGURES; etc.

FINE ARTS gives a general survey of the arts in which material functions and values become mediums for the expression of aesthetic ones. The subject of architecture is surveyed in ARCHITECTURE, and among the many articles on related arts are: INTERIOR DECORATION; INTERIOR DECORATION, HISTORY OF; IRONWORK; LANDSCAPE ARCHITECTURE; LEADWORK; and WOODWORK, DECORATIVE. A more detailed listing is given in ARCHITECTURE (ARTICLES ON).

A key article on applied arts is INDUSTRIAL DESIGN. The story of the struggle of British artists to win aesthetic recognition for various applied arts is summed up in ARTS AND CRAFTS MOVEMENT.

Articles on the fine and applied arts include, besides those mentioned above: BOOKPLATE; COSTUME DESIGN, THEATRICAL; DRESS; ENAMEL; FRAME DESIGN; FURNITURE DESIGN; GEM (for gem engraving); GLASS; ILLUMINATED MANUSCRIPTS; JEWELRY; LACE; LACQUER; LAMP; METALWORK, DECORATIVE; NUMISMATICS; POTTERY AND PORCELAIN; SILVER AND GOLD WORK; TEXTILES; EMBROIDERY; etc.

The processes of evolution and revolution by which the major philosophies of art were developed are discussed in ART, SOCIETIES OF and MUSEUMS AND GALLERIES. The influence of these processes on the economics of art is described in ART SELLING.

Trends in the teaching of art appreciation and of art as a profession are discussed in ART EDUCATION.

Primitive and preclassical forms of artistic expression are examined in PRIMITIVE ART; ARCHAEOLOGY; in the section of ANTHROPOLOGY captioned *Archaeology and the Cultural Record*; in the anthropological sections of articles on continents and many other geographical sections of articles on continents and geographical areas; and in articles on specific archaeological sites, such as ALTAMIRA CAVE; CARNAC; TROY; etc.

ART, in its most basic meaning, signifies a skill or ability. This definition holds true for its Latin antecedent, *ars*, as well as its German equivalent, *Kunst* (derived from *können*, "to be able"). One who has acquired a skill may be designated an artisan or artist according to whether his abilities are directed principally toward a utilitarian or an aesthetic purpose. While art continues to be associated with basic skills (*e.g.*, the art of gardening, the art of warfare), the term more generally carries the connotation of nonutilitarian activities: the art of painting, the art of poetry and the art of music.

A further distinction occurs in the traditional differentiation of the liberal arts and fine arts (*q.v.*). The former include those practical pursuits that facilitate freedom of expression in language (grammar), speech (rhetoric) and reasoning (logic and mathematics), as well as the studies that lead to an understanding of man's physical, social and cultural environment. The fine arts, on the other hand, are those that are cultivated more for their own sake and for the intrinsic pleasure they afford the minds and emotions of those who experience them.

The term fine arts is a translation of the French *beaux-arts*, meaning the arts concerned only with the beautiful. Because of the bureaucratic structure of the French academies, the term came to be associated primarily with sculpture and painting, the concern of the Academie des Beaux Arts. Architecture, partly owing to its semiutilitarian character, and letters and music were artifically excluded because they came under the jurisdiction of other academies. The fine arts, in any rational view, however, must be broadened to include any aesthetically directed expression in visual, verbal or auditory images and symbols. The fine arts thus would include architecture, sculpture, painting and the various related visual, plastic and graphic arts; literature in its various poetic, prosaic and dramatic forms; as well as the dance and music.

This article, however, by force of tradition, after a review of some of the broader principles that underly all the arts, will be focused primarily on the visual arts. It is organized as follows:

I. PRINCIPLES OF ART

1. Art v. Science.—While both art and science are concerned ultimately with the pursuit of truth, the processes and methods employed by the artist, on the one hand, and by the scientist, on the other, vary to a considerable degree. The scientist, whether physical or social, is concerned principally with the problem of analyzing materials or events, while the method of the artist is primarily synthesizing. The scientist isolates, breaks things down and separates matter into its constituent parts for purposes of analysis; the artist selects his materials, assembles, composes (in the literal sense of putting things together) and builds. The scientist has to concern himself with the objective world of facts and phenomena; the artist deals more with the subjective world of imagery and feeling. The sciences attempt to evolve general laws that are applicable in all cases; the arts and letters explore individual reactions and revel in the unique qualities of experience. Scientists, by increasing concern with particular fields, tend to become specialists; artists strive to give form and substance to a world view. The social scientist, with his case histories and statistical compilations, attempts to comprehend the dynamics of human behaviour and to analyze political movements. But, as Romain Rolland put it: "The political life of a nation is only a superficial part of its being; in order to learn its inner life—the source of its actions—we must penetrate to its very soul by way of its literature, its philosophy, and its art, where the ideas, the passions and the dreams of its people are reflected" (Romain Rolland, *Some Musicians of Former Days*, 4th ed., Routledge & Kegan Paul, Ltd., London).

A scientific theory once formulated is at best tentative, since the premises on which it is based are destined to be disproved or superseded by subsequent research and discovery. A work of art once completed, however, stands as a final statement for all time. Fashions and critical evaluations may change rapidly, and the work of one artist may be eclipsed by that of another and greater artist, but a particular building, statue or painting endures. It may be destroyed, to be sure, but not disproved. Out of the artist's subjectively built world he projects a moment in the world of objective values, a fragment of infinity.

The artist thus does something to make the moment last, to give permanence to the present. The artist, then, is the only victor in man's struggle against time, and the work of art is the crystallization of a moment, a link between past and future, a bridge between individual and universal experience. The broader and wider the artist builds his bridge into the infinity of the objective world, the more universal will be the values he expresses and hence the greater and more lasting his work of art.

2. Imagination and Imagery.—The wellspring of all creativity is the imagination, which manifests itself in the projection of images. One of the profoundest insights into the creative process is contained in Gen. i, 26–27: "Then God said, 'Let us make man in our image, after our likeness; . . .' So God created man in his own image, in the image of God he created him." The Godlike principle, then, can be interpreted as creativity. If God is conceived as the creative force, and man is fashioned in his image, it follows that man also possesses creative powers in his own right and in turn creates his gods in his own image. From the theoretical void, the man-artist conceives an image; from nothingness he gives birth to being; from chaos he achieves order, which is to say that by selection he conceives relationships. The development of art skills then becomes necessary in order to transmit his ideas from mind to mind. Art thus becomes a language in images and symbols by which man communicates his conceptions of order in perceptual more than conceptual terms. The role of the artist is thus to clarify, intensify, dramatize and interpret the world about him in all its physical, social and spiritual aspects.

Art as a creative process involves the activities of both artist and audience—directly in the case of the visual arts and books, and with the mediation of reader, narrator, actor or performer in the case of poetry, drama and music. The process of creativity is thus threefold with the artist as the prime mover, communicating his ideas through the performer, as his interpreter, to his audience. Each participates in the creative process, the difference being in the intensity of the stimulus and response and in the concentrated creative thought each brings to bear on the situation.

Art works are by no means confined to the products of professional artists. In such daily activities as speaking, dressing, working or playing, all participate in the projection of images. Consciously or unconsciously, everyone is involved in the process of projecting a psychological and social image of himself. Furthermore, when participating in a work of art, whether as reader, observer or listener, a person is not a mere passive receiver of images and impressions, but an active agent in the creative process. By experiencing the work of art, he must conjure up a corresponding set of images, perceptions and impressions in his own mind and imagination. The intensity of the activity, to be sure, may be less than that of the artist who produced the work, but the reader, observer or listener is nevertheless involved in the dynamic activity of responding. Through education the development of a disciplined imagination makes it possible for the eye, ear and mind to acquire perceptive vocabularies and to develop the critical faculties so that some of the finer nuances of sight and sound are distinguishable.

Mental images, aroused as they are by sensations, assume certain perceptive and symbolic forms associated with sight (*i.e.*, visual imagery), sound (auditory), taste (gustatory), smell (olfactory), touch (tactile) and muscular motion (kinaesthetic). Art expression is based principally on the so-called higher senses of sight and sound, with the other senses playing more or less indirect roles. While no fine art, for instance, is based exclusively on taste or smell, gustatory and olfactory imagery nonetheless often is used in poetry and prose to awaken corresponding sensations in the minds of readers and to intensify the vividness of description. Tactile imagery, while not the basis of an art in its own right, nevertheless is important in distinguishing the feeling for hard or soft, rough or smooth textures in architecture, sculpture and painting. Likewise kinaesthetic imagery is important in conveying the feeling of motion, either implied as in the visual arts or actual as in the dance and music.

Sensitivity to certain types of imagery predisposes the artist, as well as any other person, to one rather than another type of expression. It seems clear that a person deficient in visual imagery would not be inclined to the visual arts except perhaps as a psychological compensation for that deficiency; and that one who is insensitive to auditory imagery would not be predisposed to music. Fortunately these various types of imagery are not mutually exclusive, and most persons experience several types, with one or another dominant. A writer or reader, for instance, would tend to be primarily visual minded, and the auditory imagery of the sounds of words would play a secondary role in his experience; a musician or listener would be primarily auditory minded, visual and kinaesthetic perceptions being of less importance to him.

In some cases synaesthesia—that is, a fusion of sensations by which the experience of one sense impression conjures up that of another type—is present. Sounds, for instance, often evoke visual images such as colours. The descriptive vocabulary used in connection with the arts is evidence of the common experience of such synaesthetic perception. Painters speak of the "tone" of certain colours. Titian and Veronese have been contrasted by some critics on the basis of their preference for gold and silver "tonalities"; the tactile analogy of "warm" and "cool" colours is also used. Musicians distinguish the timbres of various instruments according to their tone "colour." Richard Strauss wrote "tone poems," or musical compositions with narrative or pictorial content, while Debussy called one of his piano pieces *Sounds and Perfumes on the Evening Air*. Synaesthesia, in which perfumes, colours, tones and textures echo each other, was rather thoroughly explored by the Symbolist poets. "There are perfumes fresh as children's flesh," wrote Baudelaire, "Soft as oboes, green as meadows . . ." (*Selected Poems From Flowers of Evil*, trans. by Geoffery Wagner, New Directions, Norfolk, Conn., 1946).

3. Creative Drive.—Man as an experiencing individual is ceaselessly seeking to bring his experience to articulate expression.

The past experience of the individual may be said to have present existence in so far as there is a mental image of it and to the degree that it is recreated by the mind. Through images of this experience he reveals his conception of his relationship to the world about him. Through these images he asks questions of life, seeks to clarify his confused impressions and to give unity and meaning to many-sided and seemingly unrelated events. Through this process of externalization the human being seeks to understand himself and to make himself understood to others.

Since the experiences of life are never finished, but flow and change constantly, no one projected image can be sufficient and final, and hence one witnesses an inexhaustible number of expressive manifestations of the human being about himself, about other human beings and about the world around him. He tries to discard the unessential and to unite and preserve the essential elements in his experience, and by creating images of certain conceptions of life he endeavours to create a coherence and a unity to life itself.

Imagination is the prime source of creative expression, and the capacity to discipline the imagination and give form and substance to its products is one of the distinguishing characteristics of a successful creative artist or an intelligent and sensitive observer or listener. The imaginational experience of a writer occurs in the shape of figures of speech, that of the visual artist in pictures, that of the composer in musical forms, that of the engineer in inventions. Free imagination usually is fanciful and undirected, while constructive imagination represents a conscious effort to create an imaginary product with a view to letting others see, hear or feel the sensations and images the artist himself experiences.

The artistic imagination thus is concerned with the creation of fictitious characters, events, scenes, situations and moods in such a way as to recreate the artist's experience in the minds and imaginations of those who come in contact with his work. In order to bridge the gap between minds, the artist must fashion some vehicle—poem, building, statue, mural, symphony—that will convey his ideas to his readers, viewers and listeners and thus make his intuitions and emotions readable, visible and audible to others.

The creative act, then, results in the concrete forms known as works of art, and it is here that the question of classification, the choice of medium and the problem of technical facility are encountered.

4. Major and Minor Arts.—The arts, for the sake of convenience, customarily have been divided on the basis of various practical, critical, aesthetic or philosophical principles. Reference has been made above to the separation of the higher and lower sense arts. Another widely found distinction is the division into major and minor categories. Architecture, sculpture, painting, literature and music are classified thus as major arts; while ceramics, furniture, tapestry, gem carving, gold and silver smithing, coin and cameo work comprise minor categories. Similar is the classification of the fine as opposed to the applied arts.

Modern thought, however, tends to reduce the distinction between arts and crafts, form and function. An equestrian statue or a monumental fountain is, to be sure, a major achievement; but a beautiful chair, despite its practicality, is also a form of sculpture and a work of art. A cathedral and a suspension bridge once were thought to be miles apart on the aesthetic scale, but in the contemporary view engineering is the alter ego of architecture in the building craft. On a more philosophical plane, the arts have been separated on the basis of their relative concreteness and abstractness, their degree of materiality and spirituality, their aspirations toward the beautiful or sublime, or their existence in space or time.

5. Analysis and Synthesis.—Once a work of art has left the hands of the artist, it obtains an existence of its own. The completed work is both an organized whole and a historical fact. As a composition—that is, a system of related parts—it can be analyzed; as a product of a definite time and place, it can be synthesized. Analysis, by breaking the work of art down into its component parts, by examining how the parts are related to the whole and how the unity in the manifold is achieved, by examining the materials the artist used in its composition, by studying the techniques the artist used to achieve his effects, can be very revealing. But while each work of art is essentially unique, it also can be placed alongside others of a similar kind, together with those originating at the same time and place, so that by comparison a pattern of development eventually may be found. The process of synthesis, then, by placing the work of art in its social and historical frame of reference, by relating the particular work to that of other contemporary artists, by viewing the work in the light of broader cultural developments and the general stream of events in its decade, century and style period, is likewise an invaluable aid to the understanding.

6. Approaches.—All in all there are essentially but three ways of approaching art: (1) theory, which includes the factors of evaluation, the setting up of critical standards, aesthetics (*q.v.*) and the philosophy of art dealing with speculation on ultimate objectives and meanings; (2) the practice of art, which has to do with the choice of mediums, the techniques employed by the artist in the performance of his craft; and (3) history, which involves placing art in its temporal context, investigating streams of influence and relating particular works to the spirit of the time in which they were produced as well as to the history of ideas in general. The remainder of this article will deal with the techniques and with the history of the visual arts.

II. TECHNIQUES OF ART

The practice of art in any given time and place cannot be divorced from historical and geographical circumstances. When, for instance, the rebuilding of the Acropolis temples in the Athens of the 5th century B.C. was contemplated, the visions of Pericles and Phidias would, of necessity, have taken an entirely different turn had it not been for the presence of the vast and fruitful marble quarries at Mt. Pentelicus only a few miles away; otherwise stone had to be transported by ship from Ionia across the Aegean sea. Likewise the sculptural genius of Michelangelo could not have developed in the direction it did, had it not been for the easy availability of marble from Carrara and elsewhere in Italy. Similarly, a young painter of talent born in 16th-century Venice could hardly have become a great fresco painter if he wished to remain and work in his native city, the damp climate of which made fresco work unfeasible and hence favoured the development of oil painting; the wealth and splendor of Venice, consequently was mirrored best in the rich, deep, warm colours of oil pigments. A pictorial artist working in the middle ages naturally would have favoured the dominant two-dimensional mode of representation in his mosaics or miniature manuscript illuminations, while his Renaissance counterpart just as naturally would have thought in terms of the three-dimensional techniques of linear and atmospheric perspective as the normal way to describe space.

An artist, then, must choose the medium in which he is to work—whether it be sculpture or painting, architecture or music, etching or engraving, water colour or oil pigments—as well as the materials, tools and methods suitable to that medium. It is also necessary for him to develop the proper skills and disciplines necessary to manipulate his materials according to his will and imagination, and to allow him to arrive at a personal solution for the expression of his ideas. In addition, he must take certain external considerations into account, such as the nature of his commission and the source of his patronage. Is his work to be seen in sacred or secular surroundings? Is his audience to be the general populace of a city like Athens or Florence, or a sophisticated aristocracy such as the court of Louis XIV? Thus inevitably, the artist's medium, materials and techniques will reflect the tastes of his time, as well as the dominant ideas and stylistic trends of his period.

An artist's personal style thus is determined quite as much by the current practice and the historical tradition of his time as by the nature of his skill, craftsmanship and technique. Fresco painting, for instance, dates back to ancient times, and while modes of representation have varied, the basic methods and procedures of fresco have changed very little since Greco-Roman

times; certain skills, on the contrary (such as encaustic painting; *q.v.*), that were widely practised in pre-Christian art eventually become obsolete, while other disciplines (such as mosaic making), after falling into disuse for a number of centuries, are revived and flourish again.

After initial experimentation new mediums and tools come into use and are quickly absorbed into contemporary practice. Thus masonite has become accepted as a surface for painting along with canvas, wood panels and other surfaces. With the increased use of metals for sculpture, the welding torch as well as the chisel is used by the sculptor. And the strength of ferro-concrete as building material has made it possible for modern architects to add the structural device of the cantilever to the more venerable systems of the post and lintel and the arch and vault.

A. Architecture

Architecture seems to be the logical starting point for any study of the visual arts because of man's necessity to shelter himself and to devise a framework for his domestic, religious and social activities. In its broadest sense architecture also includes town, city and regional planning (*see* City Planning) as well as landscape architecture (*q.v.*).

The building art, furthermore, is perhaps the best example of the partnership and basic identity of a fine and useful art, beauty and utility, form and function. A building—whether a temple, church, exhibition hall or domestic dwelling—must demonstrate the solution of the practical problems associated with its purpose.

The primary concern of the builder is the definition and articulation of exterior space and the spanning and enclosure of interior space. The moment a square or circle has been described on the ground, one area has been separated from another and the architectural process has begun. As the architect spans his space—on the ground as with a wall or road or in the air as with an arch or bridge—he encounters not only the complex technical problems of his craft but aesthetic factors as well. He must mold his materials with an eye for the proportion of masses and voids; for the qualities, textures, colours and capacities of materials; for the harmonious relationship of open windows and doors to closed wall space; for the control and flow of lighting; and above all for architecture in action—that is, for the movement of the people who will be living, working and carrying on their various activities within his building.

The history of architecture may be read in the progressive changes in the solution of structural problems. The transition from the most primitive shed roof and simple truss construction to the vertical posts, or columns, supporting horizontal beams, or lintels, covers the period from the beginning of civilization through the ancient Egyptian and Greek cultures. The Romans exploited the arch, vault and dome and made broader use of the load-bearing wall of mass masonry; and in the late medieval period the pointed arch, ribbing and pier systems gradually emerged. At this point all the problems of brick and stone masonry construction had been solved, and little innovation except in decoration was achieved until the Industrial Revolution. Not until the 19th century, with the advent of cast iron and steel construction, did a new architectural age dawn and higher, broader and lighter buildings become possible. With the advances of 20th-century technology, new structural methods such as cantilevering received more extensive use.

Building materials evolved in much the same way from the primitive grass, thatch, stick frame, wattle and daub, to clay, adobe, brick, stone and cement. The modern use of reinforced and prestressed ferro-concrete, of various metals including steel, copper and aluminum as well as of glass, has led not only to more daring structural innovations but also to greater beauty through the realization of the inherent qualities of such materials and their use in novel decorative schemes.

Thus architecture as a fine art and engineering as a practical science, after being artificially separated since the Renaissance, have again been reunited in the 20th century.

See also Architecture.

B. Sculpture

Sculpture, like architecture, is concerned with three-dimensional space; but unlike architecture it is representational in that it depicts human, animal and plant as well as abstract forms. Sculpture and architecture exist in an intimate relationship, since most exterior and interior architectural embellishment is conceived in terms of moldings, friezes, statues in niches and the like.

Sculpture can be subdivided into two categories: (1) relief (*q.v.*) sculpture, in which the figures are attached to a background and seen against a plane; and (2) free-standing sculpture, in which the figures are detached and appear in the round. Modern sculpture goes a step further in the pieces called "mobiles" and achieves a freedom of movement, part against part, by being suspended in the air. Motion itself thereby becomes the subject matter, whereas previously it could be suggested only by illusion and incipient tendency.

1. Materials.—Any material with the capacity for being shaped and retaining that shape is potential material of sculpture. Tradition has favoured wood, clay, stone, and metal as the usual choices for plastic expression. In ceramics clays of various kinds are first shaped, either by hand or with a potter's wheel, then hardened by baking. Wood carving (*q.v.*) and stone carving are also among the simplest and oldest techniques of the plastic arts, while metalwork in copper, silver and gold, as well as bronze casting, requires far more complicated processing. Modern sculptors have employed other metals, such as aluminum, iron and steel, together with such foundry techniques as welding. Their preoccupation with new materials as well as their forthright and rugged treatment of them has led to modern abstract sculpture whereby the formed material becomes its own subject matter. They likewise have experimented with industrial components such as pieces of steel with rough and jagged surfaces that are often shaped into anthropomorphic forms suggesting the intimate relationship of man and machine. Modern sculptors also have taken cognizance of the opposition of solids and voids, sometimes termed positive and negative volumes, by perforating their works. Often the masses are merely suggested by outlines of wire or planes defined by bent sheets of plastic or metal.

2. Techniques.—Sculptural techniques can be separated into two major classifications, additive and subtractive. By addition the sculptor usually works with clay, wax, plaster or some other soft material building up the work from a central nucleus, shaping and molding his three-dimensional composition from the inside out. The image then can be hardened by baking, as with terra cotta (*q.v.*), or transferred by casting into a metal such as silver or bronze. Many modern sculptors work additively by assembling pieces of wood, stone, plastic, metal or wire. In the subtractive technique a sculptor works with a block of wood or marble and carves and cuts away toward the interior, working from the outside in. Material thus is removed, and what remains becomes the final product.

Besides lines, planes, masses and plastic forms, the sculptor also must be concerned with the texture and colour of his materials as well as with the play of light and shade about them. Tactile values play an important role in the art, as is indicated by the necessity of placing "Do not touch" signs near sculptural works. Lighting also must be taken into account, and the sculptor must consider whether his finished work will be placed indoors or out, in bright light or dim, in natural or artificial light; whether the light will fall from above or be reflected upward from below; and whether it will be viewed from eye level or at a considerable height. Because of such factors as these, wrong impressions may occur when a work of sculpture is taken from its original setting and placed in a museum. The pedimental sculptures of the Parthenon, for instance, were intended to be viewed at a height of approximately 35 ft., but in the British museum they are seen at eye level. Similarly the cella frieze was designed for lighting reflected from below, but in the British museum the light falls from above. (*See* also Sculpture.)

3. Minor Three-Dimensional Arts.—A jeweler quite as much as a bronze caster works with metal. His more precious materials can be molded and are also malleable (that is, capable of

being hammered or beaten into various shapes). For ornament a design can be added by engraving or chasing or by beating a metal sheet against a mold so as to leave a relief pattern on one side, a technique called *repoussé*. Inlaying (or damascening) with other metals, plating one metal with another, and enameling (cloisonné) are also employed (*see* METALWORK, DECORATIVE; ENAMEL). In addition to such decorative arts as silver and gold work, bone and ivory carving (*q.v.*), cameo portraits, gem carving (*see* GEM) and coin making (*see* NUMISMATICS), there are the arts that combine utility with decoration, among them pottery, glass blowing, cabinetmaking, furniture designing, basket weaving, leatherwork and the modern machine arts and industrial design. *See* POTTERY AND PORCELAIN; GLASS; FURNITURE DESIGN; SILVER AND GOLD WORK; BASKET; and INDUSTRIAL DESIGN.

C. PAINTING

The image in painting, as in all the other pictorial arts (mosaic, tapestry, textiles, stained glass, engraving, etching and the like), is fictitious; that is to say, it has no physical three-dimensional existence. Since the artist works only on a surface or picture plane, he must employ certain conventional devices if he wishes to symbolize objects in space. These methods include perspective, modeling in light and shade, and the use of colour. Linear perspective takes advantage of the apparent reduction in the size of objects as they recede from the eye; atmospheric perspective suggests the haziness, softening of outlines and loss of detail as the eye looks into the distance; chiaroscuro, or the gradations between light and dark as reflected from objects, produces the effect of modeling, a term borrowed from the sculptor's vocabulary; colour perspective is based on the principle that warm colours such as red and yellow seem to project forward and cool colours such as blue and green create the illusion of recession.

1. Materials and Techniques.—The materials of which painting is composed and the techniques that organize the materials are closely related. The three materials of painting are (1) the surface, also called the ground; (2) the pigments employed to make the colours; and (3) the tools used to spread the paint on the surface.

The term medium in painting has a special meaning, referring to the vehicle in which the powdered colours, or pigments, are suspended and which binds the pigments to the surface. One medium is pastel (*q.v.*), in which the powdered colours are compressed into pencillike sticks, or crayons, and then spread directly onto the paper; in order to assure permanence, a fixative must be sprayed on the work when it is finished. Another is water colour, in which the pigments are suspended and their tone controlled by the proportion of water; the usual surface is paper or silk (*see* WATER-COLOUR PAINTING). In the technique known as *gouache* (*q.v.*), the addition to the water colours of an opaque filler such as zinc white makes certain textured and bright-hued effects possible.

Fresco (*see* FRESCO PAINTING) means painting with water colours on a wet lime-plaster ground, usually a wall or ceiling surface; the paints and plaster combine chemically to dry into a permanent surface and become part of the wall itself. With tempera (*q.v.*) the binding medium is egg yolk, or some other viscous substance; remarkably permanent and capable of brilliant colour effects and precise detail, tempera can be used not only for mural painting but also can be applied to wooden panels, parchment and the like. Casein, a milk-based vehicle, has found favour as a tempera type of painting.

Oil is perhaps the most flexible of all vehicles (*see* OIL PAINTING, TECHNIQUE OF). Slow in drying, it allows the painter time to consider and correct his work until the desired quality is achieved. Oil paints, unlike the more opaque tempera, are translucent and thus allow light to be refracted; luminous surfaces and certain shimmering effects thus are obtainable.

Experiments have been made with synthetic lacquers and pyroxilins such as Duco as mediums for painting. Mexican muralists have employed such mediums, often spraying them on a ground of Portland cement.

2. Application of Pigment.—The painter ordinarily spreads his pigments on the surface with brushes of various sizes and with bristles of varying textures. Flexible palette knives, spatulas, the handle of the brush, and the fingers sometimes have been used by artists to achieve certain textures and qualities. Some even pour the paint directly on the canvas; others use an airbrush, run by compressed air from a pump, to spray paint on the surface in a fine mist.

Although painting is a two-dimensional art, an artist occasionally will employ certain techniques that add a third dimension to the picture plane. The texture of the canvas itself may be used, or the gesso sizing can be thick in texture. The painter then builds up his picture with thick pigments, called impasto, or he may smear lighter-coloured paints over darker ones with a "dry" brush to vary the texture in the technique called scumbling. Painters also have experimented with adding sand, pebbles and other materials to their pigments to give thicker-textured and three-dimensional effects. They also may desire the opposite effect and paint layer after layer of thin transparent pigments over each other permitting colours to shine through each other. This technique, called glazing, permits delicate and subtle colour modulation, thin textures and precise delineation of detail.

In most oil painting the mixing of colours is done as little as possible on the palette, since it renders them muddy and dull; rather, the mixing is done on the picture surface itself, thus permitting the colours to fuse and blend more directly. Or the artist may not mix his colours at all, but place, for example, his yellows and blues side by side in small dots or splotches, allowing the eye of the beholder to blend the hues and give the effect of a lively green. Such techniques, called optical mixing and pointillism, were used extensively by the Impressionists to suggest the vibrant nature of sunlight.

Though many other arts use colour in their expression, in no art is colour so fundamental as it is in painting.

See also PAINTING.

3. Allied Arts.—Parenthetical mention should be made of allied types of mural decoration (*see* MURAL PAINTING) such as mosaics, textile wall hangings and glass painting. The technique of mosaic (*q.v.*) requires the placement of many small, flat, variously-tinted pieces of stone or glass, called tesserae, into a mortar ground, which is then bound with cement. A rich and sparkling surface is produced, and though pictorial effects such as light and shade as well as perspective can be suggested, the nature of the medium is best realized in two-dimensional patterns of a semi-abstract or abstract style. This is also the case with stained glass (*q.v.*) as well as with the textile arts, tapestry and embroidery. Cloth and tapestry weaving (*see* TAPESTRY) calls for the coloured threads to become a part of the cloth—the warp, as it were, worked into the woof to make the resulting design or image a part of the fabric itself. Embroidery, by contrast, uses the technique of superimposing the design by stitching it onto a plain fabric background. The artist can also make his designs by stamping or painting them on a plain piece of cloth, a process much favoured in modern, machine-manufactured fabrics. *See* EMBROIDERY; TEXTILES.

D. DRAWING AND THE GRAPHIC ARTS

Drawing (*q.v.*) is an art in itself and an indispensable technique for other arts. Architects, sculptors and painters usually set their first ideas down as quick sketches. As the artist's ideas crystallize, a series of preparatory studies may pave the way for the final work, or the drawing itself may eventually become the finished work. There exist many fine drawings by almost all the great western masters, as well as vast numbers of drawings of great sublety from Chinese and Japanese artists. A fairly wide range of drawing tools and materials has been traditionally available to the artist; the surface has usually been paper, though many oriental drawings are done with brush and ink on silk, which in turn is mounted on paper. Besides the common pencil, pen and ink, chalk and charcoal sticks, the artist also may use crayon of various types, or silverpoint, a somewhat more complex technique in which the artist uses a paper prepared with a fine abrasive coating that retains bits of metal scratched off the sharp

silverpoint stylus as it moves across the surface. (*See* also PENCIL DRAWING; PEN DRAWING; CRAYON DRAWING.)

An artist may be drawn to the graphic arts partly because they place at his command a wide range of effects not available in any other medium, and also because through mechanical reproduction many copies may be made from a single plate, enabling him to reach a larger public. The end of the graphic process is a print—an inked impression, usually on paper, made from a previously prepared plate. The two principal methods for making the plate are relief and intaglio. The relief technique is employed, as in the case of wood and linoleum cuts, when the lines the artist has cut are not inked, but only the remaining smooth surface is inked and transferred to the paper. With intaglio the process is reversed, and the lines cut into the copper, zinc or steel plate are inked, while the remaining surface is wiped clean and becomes blank on the paper.

The chief methods of working the surfaces of metal plates are engraving, etching and dry point. With engraving (*see* ENGRAVING, LINE) a steel graver, or burin, is pushed over the plate with sufficient pressure to cut lines in the metal. In dry point (*q.v.*) the stylus is pulled as with a pen. The burr, or raised edge, is usually scraped off so as to leave a clear precise line. Sometimes, as in the case of dry point, it is left on the plate in order to give the line a soft, fuzzy edge. In etching (*q.v.*) the plate is first coated with a wax or varnish through which the artist scratches his lines with an etching needle. The plate is then dipped into a corrosive acid, which etches, or bites, into the exposed parts of the metal. Upon removal of the surface coating, the remaining lines are inked and the plate is ready for printing. The etcher has the advantage of working with soft wax material, which makes greater subtleties of line, tone and shadow effects possible. In the technique known as aquatint (*q.v.*), not only lines but tones, shadows or large areas of various grays may first be etched into the plate by carefully sprinkling the wax on the plate rather than by coating it completely. Or in mezzotint (*q.v.*), the burr may be raised on the metal plate mechanically rather than chemically by the use of a rocker, or tool that roughs a larger surface at one time.

Other techniques common to the graphic arts are lithography, aquatone and serigraphy, as well as photography. Lithography (*see* LITHOGRAPH), as the name implies, entails drawing on a special kind of polished stone, though metal plates also are used. Subtleties of shading, tone and line are more readily available in lithography than in other graphic mediums because the artist has the greater freedom of drawing directly on the plate with grease crayons or brushes with special inks. In serigraphy, or the art of silk screen (*see* SILK SCREEN PRINTING), paints are squeezed through a special cloth masked with a stencil so that only certain areas permit the colours to pass through to the surface of the paper beneath. Invented in the 19th century, the methods and techniques of silk screen have been raised to the status of an important art form. Photography (*see* PHOTOGRAPHIC ART) is basically a simple process of exposing light-sensitive, chemically treated materials to light-reflecting objects, which are then recorded on a plate of film. The processes, materials and equipment employed by photographers have become extremely complex, flexible and sensitive. The most varied and subtle effects can be achieved by this graphic method, which takes modern chemistry and optics into account.

E. CONTENT

1. Traditional Categories.—Traditionally the subject matter of the pictorial arts is divided into various categories. (1) In historical scenes, including mythological and religious events, the artist usually is concerned with epical subjects and many figures placed in large-scale settings. (2) Genre (*q.v.*) pictures, by contrast, include casual, everyday situations such as a family at supper or a group playing cards. Such subjects are not the epic stuff of history, but lend themselves to informal, genial, sometimes humorous treatment, usually tempered with the warmth of human sympathy. (3) Portraiture (*see* PORTRAIT PAINTING) and figure painting, including academic studies of the nude, constitute still another branch of traditional subject matter. (4) Landscapes (*see* LANDSCAPE PAINTING), including seascapes and cityscapes, are pictures in which scenery assumes major interest. When human or animal figures are included they are of secondary importance. (5) Then, if landscape represents the larger aspects of man's environment, still life (*q.v.*) becomes the smaller, interior and more detailed view. Still-life pictures usually are composed of static arrangements of fruit and flowers, or a thoughtful grouping of inanimate objects on a table.

2. Abstract and Imaginary Art.—While these categories are still valid for traditional art, the 20th century has witnessed a break with the past, so sharp that it becomes necessary to add still another division for abstract and imaginary art. In the one case the picture does not describe or refer to the world outside itself, but rather, by an abstract play of lines, shapes and colours, the picture is self-identifying and its own referent. In the other, by conjuring up phantasms from the inner psychological world of emotion and imagination, the picture becomes a revelation of the artist's unconscious reactions.

In the various movements—cubism, nonobjectivism, expressionism, surrealism, fantastic art, to name a few—contemporary artists attempt to see the world with new eyes, to distill the essence of things rather than represent their external appearance, and to construct a subjective reality out of their own imaginations. This can mean anything from the distortion of natural shapes to the invention of new forms independent of those found in nature. In abstract design, the artist tries arbitrarily to free line, colour and form from nature and to emphasize the essential order of things as he understands them. Fantastic art and surrealism, on the other hand, look inward toward an introspective dream world of emotions and psychological states. Salvador Dali has called his pictures "hand-painted dream photographs," and the surrealist André Breton declared such art to be "pure psychic automatism."

3. Modifications in Sculpture and Graphic Arts.—Some modification of these categories must be made for sculpture and the graphic arts. Sculpture, like painting, has always dealt with historical subjects (both religious and secular), as well as with genre and portraiture, and, in the 20th century, with abstract and imaginary plastic forms. Landscape and still life, however, play only an incidental part in sculptural expression. Such devices as a tree trunk, the shape or texture of a rock, the element of water as with fountain groups serve to suggest the placement of figures amid natural surroundings; or a sculpture composition may include an arrangement of flowers, fruits or other still-life components.

While the pictorial ingredients of the graphic arts can include all those of painting, a subtle relationship between form and content and between the limitations of a medium and the choice of subject is involved. Shakespeare, for instance, casts his tragedies in the monumental mold of poetic drama, but for more tender and lyrical expressions he chooses the sonnet. Similarly, a visual artist must take the nature of his medium into account. If the theme is of heroic proportions, a fresco mural or large canvas is in order, but casual and intimate subjects find themselves more at home in the dimensions of an etching or lithograph.

F. CONCERTS OF ARTS

In addition to the relatively independent arts, there are composite arts—such as religious monuments, the theatre arts and opera—that result from collaboration of artists from many fields. More than the work of stonemasons, sculptors and glass painters are those collective outbursts of medieval creative energy known as cathedrals. Here the constellations of breathtaking vaults, proliferation of sculptured forms, mysterious colour harmonies of stained glass, merge with choral chant and the sacred liturgy to form one grand architectonic design. Similarly, a theatre or opera production entails the setting of a theatre building, scenic architecture, sculptured properties, costumes, dramatic movement of human figures, plot and dialogue, dance interludes or ballet, spoken or sung melody, solo, choral and instrumental music, and an incidental or full score.

These concerts of the arts apparently had their origin in pri-

mordial religious rites that eventually took the shape of the more stylized sacred liturgies and such art forms as the Greek drama. Medieval mystery, miracle, morality and passion plays, as well as the popular forms of minstrelsy, combined elements of dramatic action, spoken dialogue, poetry, solo and choral chant and pantomime. Renaissance Florence witnessed such elaborate pageants as the *canti carnascialeschi*, or carnival songs of the pre-Lenten celebrations, and the *Calendimaggio*, or May-season entertainments, that included outdoor singing and dancing by masked merrymakers, mimicry, tableaux and torchlight processions with elaborately designed floats and chariots representing mythological or historical events. Lorenzo de' Medici himself wrote some of these so-called triumphs, and the foremost visual artists of the time—Ghirlandajo, Verrocchio, Leonardo da Vinci and Andrea del Sarto—did not disdain to design the scenes and machines for them.

History records some notable examples of these composite artistic ventures of the past. The poet Angelo Politian collaborated with the composer Germi on an *Orfeo* at Mantua in 1474. The presentation was modeled on the sacred representations and pastoral plays of the period, which included dialogue, solo and choral song, instrumental interludes, ballets, pantomime, plot and scenic spectacle. In Renaissance Rome, Pope Leo X, son of Lorenzo the Magnificent, in 1518 patronized a production of a poetic comedy by Ariosto that included dancing, instrumental music and scenery painted by Raphael. The English court masque was a combination of these Italian triumphs and the French court ballet. For the *Masque of Blackness*, performed in 1605 at the court of James I, Shakespeare's junior contemporary Ben Jonson wrote the text and the architect Inigo Jones designed the scenery, which involved nothing less than the invention of movable stage sets. Nor is the 20th century wanting in this respect. Sergei Diaghilev assembled in Paris for his Russian ballet productions such leading lights as the composers Debussy, Ravel and Stravinsky; the scenic designers Bakst, Derain, Matisse and Picasso; the choreographers Fokine and Massine; and the dancers Karsavina and Nijinsky.

III. HISTORY

Ultimately what matters in art, as Lionel Venturi pointed out in the case of painting, "is not the canvas, the hue of oil or tempera, the anatomical structure, and all the other measurable items, but its contribution to our life, its suggestions to our sensations, feeling and imagination." (Lionel Venturi, *Painting and Painters*, p. 10, Charles Scribner's Sons, New York, 1945). The history of art reflects the conflicts of social forces, the rivalries of cities and states, the ambitions of priests and rulers, the competition among public and private patrons. The human urge to create order and build, decorate and depict, impress and express are the constants of art history, while the dynamics of society, the momentum of particular art movements, the fluctuation of shapes and forms, the evolution of techniques and the vagaries of group and individual tastes are its variables.

When a centre of population attains a degree of civilization, develops a prosperous economy, fosters an adequate educational system and produces a number of talented persons, a cultural climax may occur. Usually this happens because some person of powerful and persuasive convictions reacts strongly enough to the challenge of his age to reach a position of prominence and influence. Various arguments have been advanced, such as the "great man" theory, according to which outstanding persons stamp their image upon their age, and genius is the primary causal influence on history. Social realists, on the other hand, contend that environmental forces shape the personality and product of the individual. The truth probably lies somewhere between these extremes of nature and nurture; the interplay between powerful personalities and the stimulus of their times brings about the explosion commonly described as genius.

Such a cultural climax may be instigated or encouraged by a single or collective patron with energy and discernment. The patron might be an individual ruler with the vision and means possessed by Pericles, who built the Acropolis temples and fostered the poetry and drama that combined to produce the aesthetic climax of ancient Athens. Or it might be a family of merchant princes such as the Medici who brought Renaissance Florence to its high point of development. In the 20th century the Commonwealth of India became the patron of Le Corbusier, whose commission was nothing less than the construction of an entirely new city, complete with every public and private architectural facility. Modern industrialists have contributed to New York city such cultural complexes as Rockefeller centre, and have joined with the city planning commission as well as other public and private contributors to erect the Lincoln Square "Acropolis" that embraces an opera house, several concert halls, a repertory theatre, a library and educational centre, as well as co-operative housing units.

Taken as a whole the arts of a given time and period usually demonstrate a certain unity of direction. Yet this unity does not lie in the separate objects or techniques of production; its focus is found in minds capable of perception and understanding. A search for the common idea that animates and motivates human activities often can reduce to basic simplicity what appears on the surface to be a confusing multiplicity of actions and directions. And since the arts usually are not experienced separately but simultaneously, comprehension may be sought multidirectionally.

If a common idea or configuration of ideas can be found, then elements that previously were not understood begin to fall into place and to acquire significance. Techniques of production, of course, are and always will remain private problems to the particular craftsman, but the idea of composition, used here in its basic sense of putting things together, is common to all. An architect puts bricks together, a poet words, a musician tones, but they do not do so in a vacuum of abstractions; they do so rather for purposes of expression and communication of thought, free fantasy, social comment, satirical observation, self-revelation, construction of new orders and the like. Highly important is the fact that the artist's viewpoint has been coloured and shaped by a social and historical environment, and his works are addressed to some segment of the contemporary order. Whether the artist accepts or rejects, endorses or protests, constructs or destroys, his taking-off point must be his own period. Some artists function largely within their own time, having little to say to posterity and hence passing eventually into oblivion. Others speak in broader humanistic terms so that they transcend their own times, and their works are consequently significant enough to ensure their survival.

Through its artists, society can see, hear and feel aspects of its world that it never experienced before. Similarly, by training his perceptions and sensitizing his eyes and ears to sight and sound the individual observer, reader or listener may discover a new and richer world. The insight of the artist thus can help to create a larger world outlook; through the arts it is possible to participate in the intellectual and emotional currents of the past and present. The visual arts can present the visage of an age through historical painting, portraiture, scenes from daily life; while poetry and music, by revealing emotion, can yield deeper understanding of present as well as past life. Song and lyric poetry reflect the joys and sorrows of the people who sang them. Dances reveal the inner rhythms as well as the outer gestures and steps of the individuals and groups who have performed them. The drama and lyric stage, including opera, is a rich source of social commentary, replete with conceptions of order, manners and characteristic attitudes of a given time. The music of a period tells not only of its harmonies but also of its conflicts: in periods of oppression it represents the passionate outpouring of the human heart; during religious revivals, it sings out with resounding declarations of faith; in an age of reason, it bespeaks the logical processes of well-ordered minds; and during social upheaval, it rings out with revolutionary anthems.

It is the artist, then, who most poignantly expresses the spirit of his age. The poet, as leader, establishes goals and ends for human living. He opens up new areas of potential experience and gives structure to that experience by creating images of order. He can convince the individual that life is not an incoherent sequence of events but a force that has a definite direction, unity and meaning in which particular events are subordinated to a

larger whole. A work of art is always a reflection of both the personality of the artist and the age in which it was produced. Paintings, for instance, often speak more eloquently than do historical treatises and other documentary evidence. Titian in a portrait of Charles V has contributed some vital substance that allows the viewer to visualize the qualities of a living human being as he appeared to one of the subtlest and most alert minds of his age. In art the past continues to exist as a living process; its arbitrary separation from present and future disappears. True understanding of human life and history can come only by relating one event to another and eventually to the entire stream of universal life from which each derives its significance; in achieving such a relation art plays the vital role.

A. Prehistoric and Early Near Eastern Styles

The origins of art in preliterate times can be discerned dimly in the caves of the nomadic hunter-artists of the Paleolithic Age (*c.* 25,000–10,000 B.C.) and in the lake dwellings and agricultural settlements of their Neolithic Age (*c.* 10,000–4,000 B.C.) successors. Various theories about the important and vital place of art expression in the activities of early man have been formulated: some feel that art is the expression of an affirmative attitude and the joy of life; others see fear as an impetus to artistic creation. Primitive man seems to have enjoyed ornamenting his clothing, tools and weapons and decorating his baskets and pottery; but he likewise fashioned idols and fetishes, presumably in order to propitiate hostile spirits in magic ceremonies and thus to bring the more mysterious forces of the universe under his control. To some students primitive art represents the delight in exercising the play instinct during leisure time; to others it is a by-product of the struggle for existence, the psychological need to assert the self in the face of an overwhelmingly hostile and brutal world. Some see early man's art as originating in the desire to cover blank surfaces with lines, shapes and patterns; others feel that it is based on deeper spiritual aspirations and the worship of superpersonal beings.

1. Early Man.—Already manifest in these early times is the polarity between a naturalistic recording of observed phenomena and the tendency to symbolize unseen forces in formal patterns and abstract designs. The Paleolithic artist covered the surfaces of caves and rocks with richly coloured, lifelike bisons and mammoths. With amazing accuracy and keen powers of observation, the cave artists saw and recorded details of animal anatomy, its musculature at rest and in action. Unconcerned with tradition or convention, Paleolithic art was the reflection of a highly individualistic attitude toward life.

The shift from hunting to agricultural life brought about corresponding changes in art, and art of the Neolithic period shows a trend to severe geometrical design. Instead of merely representing the visible world, Neolithic man appears to have been concerned with the invisible forces that controlled his destiny. Natural observation and recording gave way to stylized signs and symbols that stood perhaps for the unseen forces and hidden inner substances. In an agricultural world that alternated between plenty and scarcity, man's livelihood and destiny depended upon such capricious factors as the fertility of domestic animals, the alternation of sunshine and rain, threats of drought and flood, storm and wind. Such forces do not lend themselves to realistic treatment, and hence must be represented by signs and symbols or personified by masks or totems. Neolithic geometrism bespoke a more integrated social organization, uniformity of social attitudes and acceptance of conventions. (*See* Primitive Art.)

2. Egypt, Mesopotamia and the Aegean.—With the coming of the city cultures of the great river valleys—the Tigris, Euphrates, Indus and Nile—concentration of population allowed for a more varied life as well as for a greater stratification of social levels. In both the near and far east, art expression, with occasional exceptions, was essentially a continuation and refinement of the formal geometrical style of Neolithic times. The ceremonial and courtly arts that developed in Mesopotamia and Egypt reflected the splendour and magnificence of a superindividual, aloof ruling class, whose life was inexorably regulated by a rigid etiquette and conformity to convention. All individuality was suppressed under a veneer of stereotypes and archetypes. This art was the product of temple and palace workshops in which generations of anonymous artisans and craftsmen laboured and in which the personality of the artist-designer invariably was concealed. It was an art created not to be admired and enjoyed but to impress potential enemies with the rulers' power or to preserve their bodies and souls for eternity. Hence its remains are found not only in public places, but also in remote temple sanctuaries and in tombs.

Neither the conservative aristocracy nor the priestly caste desired change in the social structure. Consequently those masterly solids, the ziggurat (*q.v.*) towers and pyramids (*q.v.*), that practically negated interior space, the pylon-faced temples with their forests of painted columns, the immense palaces, the obelisks, the stylized friezes of solemn and stately processions, winged lions and sphinxes, are massively static and endlessly repetitive. Because prince and priest had to adhere to rigid convention in order to proclaim and maintain their worldly position, only subhuman creatures could become emotionally expressive; hence representations of animals became the most human aspect of art.

Two exceptions to these stylized, hieratic expressions were a brief interlude that coincided with the reign of Ikhnaton (*q.v.*) in Egypt, and the longer-lived culture of Crete and Mycenae. Ikhnaton broke with the past not only in his adoption of monotheism but also in his conscious innovations in art. Portraits of him and his queen, Nefertiti, as well as the informal scenes depicting his court, reveal truly individual personalities with real human warmth. The animated, lively Minoan style of Crete, afterward continued on the mainland at Mycenae, mirrored a gay, chivalrous, luxurious courtly life (*see* Aegean Civilization). Difference rather than sameness, diversity rather than uniformity, spontaneity rather than study, flexible forms rather than strict symmetry characterized this colourful and imaginative art.

See also Egyptian Architecture; Jewish Art; Persian Art; Pre-hellenic Architecture.

B. Classical Styles

It remained for the Greeks to synthesize these opposing tendencies in Mediterranean art. After a slow germination during the Archaic period, the abstract geometrism of the near east and the spontaneous naturalism of the Minoan-Mycenaean culture, the decorative elegance of the Ionian merchant cities and the solid strength of the Dorian agricultural communities—east and west, in short—met and merged and eventually flowered into the classical art of antiquity. Throughout the successive periods of Hellenic, Hellenistic and Roman domination (roughly the millennium spanning the five centuries before and after Christ), and despite the social evolution from city-state and kingdom to world empire, this balance between the extremes of naturalistic uniqueness and stylized convention was maintained. Though the scales could tip at any time in one direction or the other, the precarious balance between democratic individualism and aristocratic traditionalism, the actual and the ideal, the changing world of appearances and the permanent realm of abiding principles, spontaneity and self-restraint, emotional and intellectual elements somehow was maintained. Classical art was never wholly one or the other, but in the work of various generations, geographical centres and schools of artists now one aspect was predominant, now another.

The declared principle of Greek aesthetics was the imitation, or representation, of nature. Taken at face value this would be a straightforward naturalism, and to some extent it was; Myron's bronze "Heifer" on the Acropolis at Athens, for example, was so lifelike that cows were said to low at it as they passed by. But the desire to idealize, to perfect, to create types, to work out canons of proportion and rational concepts of order invariably asserted itself.

The history of art knows no event more momentous than the aesthetic revolution brought about by the Greeks. Art emerged from the tomb and from dim temple sanctuaries into the light of day, where it could be seen and admired by all. No longer was art a form of propaganda; it became a free pursuit of creative truth

and a method of interpreting reality. Ponderous pyramids, with their overwhelming weight and size, yielded to perfectly proportioned temples conceived as dwelling places for benign deities. No longer were the gods conceived as mighty monsters but as perfect human beings endowed with attributes of physical beauty. No longer was art the work of anonymous craftsmen; artists now acquired individual reputations, and their works exhibit personal style. Beauty in the Greek conception was equated with truth and goodness in a trinity of eternal verities, and aesthetic activity was raised to the level of intellectual and moral pursuits. Physical or visible beauty could lead the mind of the beholder to thoughts of the divine, and through the contemplation of eternal beauty man could obtain glimpses of the moral order of the universe.

Such lofty ideas, however, still allowed ample scope for personal expression. Individual differences were explored along with the establishment of types and archetypes; sensuous and intellectual pleasures were found not to be mutually exclusive; capricious differences could coexist with accepted conventions; personal hero worship in portraiture and biography found a place beside admiration for abstract ideals; architects concerned themselves with city planning and domestic dwellings as well as with temples and shrines; utilitarianism in engineering projects such as aqueducts and bridges was not incompatible with concepts of beauty; and painters depicted casual genre scenes as well as vast mythological and historical subjects.

Above all, perhaps, the Greeks established the ideal of man as the measure of all things, a concept that has illuminated all succeeding phases of classicism in western art. To the Greeks art was an adjunct to the good life, the material embodiment of spiritual attributes, the harmonious reconciliation of man and his environment. Nature was humanized by personification; even in such fanciful creatures as the goat-footed Pan and the centaurs, the human body was always the point of departure. Classical architecture, furthermore, humanized the experience of space by imposing special limitations that rendered it intelligible to the eye as well as the mind. The Greeks defined space in terms of lines and planes and banished mystery from the building process by making all parts of their temples clear and self-explanatory. The Romans went a step farther in expanding and developing interior space and in learning to control and manipulate it as a sculptor molds his materials.

In all cases the point of reference was man, his activities and movements. The anthropomorphic idea of the gods gave impetus to the perfection and idealization of the human body, and sculptors evolved canons of proportion—*i.e.*, systems of measurements in modules—by which each part of the body in a particular statue is logically and integrally related to the whole. Classical art with its criteria of moderation, balance, order and clarity has stood as a model and inspiration to all subsequent generations. Across the centuries, it has been an ideal to be studied and emulated, a standard for critical comparisons, a basis for judgment.

See also Greek Architecture; Greek Art; Roman Architecture; Roman Art.

C. Oriental Parallels

By the end of the classical era both occident and orient had arrived at critical principles and criteria of judgment. The line of thought in the west runs from Aristotle's *Poetics* and the Neo-Platonists, through the ancient treatises on rhetoric, poetry, music and the visual arts, to the commentaries of St. Augustine and Boethius. The basic tenets of oriental art were formulated in China by Hsieh Ho about the 5th century. His *Six Canons of Painting*, which have constituted the basis of oriental art criticism ever since, are arranged in the order of their importance: (1) life rhythm engendered by spiritual harmony; (2) correct use of the brush in delineating structure and anatomy; (3) rendering of forms in keeping with the objects; (4) application of colours appropriate to the kinds; (5) spacing based on proper planning; and (6) emulating classic pictures in order to preserve tradition.

To be recognized as a masterpiece, a work must qualify on all six points. It will also be noted that first and foremost an artist must concern himself more with interpretation than with representation, more with the spirit than with the semblance of his subject. The other five rules have to do with technical considerations—the lines and brush strokes, or skeleton that supports the spirit; the forms and colours, or flesh and skin that enclose it; the spacing or arrangement of the design; and copying that transmits the principles established by the old masters. The brush strokes by which the oriental artist puts his conception into execution are never static entities but the invocation of living motion, the nerve system of his composition. Sketching from nature and colouring likewise are dynamic processes that included training the artist's perception by observation, grasping the spirit inherent in objects, pondering on the mystery of animate and inanimate objects and identifying himself with his subjects. In painting a plant or tree, furthermore, the oriental artist follows the natural order of growth, drawing the roots first and proceeding upward.

Rules of composition based on Hsieh Ho's canons have been amplified at various times. The order and relationship of principal and subordinate parts are carefully distinguished, with the former as the major portion of the design and the latter as its adjunct. The principal is the focal centre of attention, larger in size and more abundant in detail; the subordinate is smaller in proportion, supporting, complementing and balancing the principal. In a portrait of an emperor, for instance, the personality is the principal, and the palace, furniture and garden are the subordinate accessories. The artist must always be conscious of the dominant characteristics, attributes and ideals of his subjects—in human subjects, the dignity of a ruler, the courage of a warrior, the refinement of a lady, the rusticity of a farmer; in animals, the plumage of a peacock, the beak and talons of an eagle, the horns of a deer. In figure drawing the oriental canon prescribes that the head should be twice the size of the open palm of the subject's hand; when standing, the height of the figure should be seven times the size of the head, when seated only three times.

Oriental conventions for representing perspective differ from occidental. The picture is built in three planes, one above the other, with the nearest objects in the lowest plane. The tones of ink or colour are graded accordingly, with the darkest tones in the foreground, medium in the middle and lightest in the background. Likewise the degree of representing detail is arranged accordingly, with distant objects being less distinct. This does not imply that such details are absent; they merely appear as if they were not present. The total effect thus amounts to aerial rather than linear perspective, and the artist must decide how to suggest spatial and temporal relationships within a restricted area. This involves grasping the essential attributes of a subject, then rendering them with the utmost economy of means. Every extraneous detail must be omitted, and what is left out of a picture is often more important than what is included. One of the most felicitous aspects of oriental painting is precisely this uncluttered appearance, allowing the observer's imagination free play.

Copying, as part of rule six, was probably not intended to be taken literally, but rather in the sense of interpreting and preserving traditions, acknowledging that the past is inevitably a part of the present, and recognizing that art parts company with the past as its own peril. Reverence for tradition and the habit of looking to the past for inspiration, however, is deeply ingrained in the oriental artist. Time-tested techniques and hallowed treatment of subject matter plays a far greater part in eastern than in western art. Schools of mannerism, by which artists seek models in the work of other painters rather than from nature, abound in oriental art. Stylization (*i.e.*, using conventional devices and accepted modes of representation rather than seeking new solutions to technical problems) leads to a certain repetitiousness both of subjects and their treatment.

D. Medieval Styles

After the fall of Rome and the dissolution of the Pax Romana,

the situation in the western world was one of disunity and confusion. The middle ages comprise, in time, roughly the millennium between the 5th and 15th centuries; *i.e.*, from the early Roman and Byzantine Christian periods, through the barbarian invasions and the successive European dynasties, to the emergence of the Romanesque and the climax of the Gothic styles. Geographically the middle ages may be said to have covered the Mediterranean world and all of Europe. Thus multiplicity and variety are more characteristic of the medieval styles than unity, and a diverse rather than a homogeneous culture prevailed.

As Christianity came to maturity in the final phases of the Roman empire, the arts were drawn into the orbit of the church, which was extending its influence over all aspects of political, social, intellectual and cultural life. There was a reorientation from a physical to a metaphysical view of life, a turning away from the natural world toward the supernatural, from the visible to the invisible.

Johannes Scotus Erigena, a 9th-century theologian, expressed the patristic viewpoint in his fear that sacred pictures, if beautiful, might lead the faithful toward an appreciation of the seen rather than the unseen world, toward false rather than true beauty. According to Scotus, God created the world of appearances in order to reveal himself in visible form to those who could not see the invisible. The fall of Adam came about when he took delight in the tangible aspects of creation before he had arrived at the perfect state of wisdom in which he would have praised the Creator before the things created. Hence the lesson of the Fall was to learn the nature of God first, then to contemplate beauty in its sensible forms and praise the Creator. It is therefore possible to enjoy beauty only on condition that it is seen as the revelation of the glory of God and not as a gratification of sensuous desire. Scotus thus left one door open to aesthetic expression.

Knowledge of the criteria of classical art is not particularly helpful in understanding medieval styles. While late Roman building methods and modes of representation continued in modified form, such criteria as canons of proportion, correct use of classical architectural orders and symmetrical design do not apply. Medieval architecture, sculpture and painting actually emphasized the irregular, asymmetry and eccentricity. The walls of Romanesque buildings often are not parallel; the angles of the vaulting sometimes are askew; the arches in arcades frequently are not of uniform height; and Romanesque and Gothic sculptors delighted in apocalyptic grotesqueries.

This metaphysical orientation could not be expected to find its models in nature. Objective observation yielded to subjective feeling. The open, exterior colonnades of Greco-Roman temples were succeeded by the enclosed interior arcades of Christian basilicas, and the earthbound horizontality of classical architecture was replaced by aspiring Romanesque and Gothic verticality. In sculpture and the pictorial arts the three dimensions of classical space yielded to two-dimensional illusionism. To depict the infinitely remote and unfathomably mysterious realm of the spirit, medieval artists had to devise an elaborate system of symbols. God the Father, for instance, became a hand pointing downward from above; the Son was represented by the chrismon (an abbreviation of Christ formed by a combination of the Greek letters Chi and Rho); and the Holy Spirit was a dove.

Evolution of church forms is most characteristic of the changing medieval styles. Romanesque abbey churches were designed for monastic communities, while Gothic cathedrals had to take the needs of growing city populations into account. The isolation of Romanesque monasteries contrasted with the greater accessibility of city churches, and during festival periods a cathedral might need to accommodate an entire town's population in addition to a contingent of pilgrims. The cathedral choir and presbytery evolved, for example, to provide space for a large participating clergy. Porches and portals at the ends of transepts, often more elaborate than those of the west façades, had to be developed to allow for entrance and egress of large crowds. In the abbey church, where many services took place at night, the need for interior light was minimized, while a cathedral's congregation, assembling by day, required larger windows and an increased use of glass. And while the embellishments of abbey churches were concentrated on the interior, Gothic cathedrals, facing as they did toward market places and city squares, called for interesting and significant exteriors. In the sculptures that graced such façades and porches all contemporary knowledge was recorded in a symbolic language of stone.

Through the medium of stained glass, the ultimate in the etherealization of interior space was achieved. Light itself became a building material that the architect, with the collaboration of the glazier, could manipulate at will. Through his glass-curtain walls, exteriors and interiors became unified, and the architect was in complete control of the flow of light. Physical light was transmuted into metaphysical illumination, and interiors seemed to be lighted not by the outer rays of the sun but by the inner radiance of the spirit. The loftiest expression of the middle ages is thus found in these miracles of soaring stone and gleaming glass, the Gothic cathedrals, which were the end result of an amazing co-ordination of community effort in concert with a spirit of religious exaltation.

Reflected in Gothic art are many of the social, political and intellectual dissonances that affirm the vigour and vitality of the period. The struggles between town and country, feudal lords and monarch, kingdom and empire, church and state, monastic and secular clergy, sacred and secular aspects of life, knowledge and faith, reason and feeling were either at or just beneath the surface. By bold thinking and intellectual adroitness the mind attempted to reconcile these irreconcilables. Remarkably, the period was able to effect a balance, however temporary, between such sharp divergencies. Some of the ingenious solutions are found in the monarchy that divided powers between king and feudal lord; in the code of chivalry that effected a balance between strong and weak; the courts of love that upheld ideal love against both marriages of convenience and gratification of the senses; in the art of counterpoint that harmonized note against note, consonance and dissonance, in two or more divergent musical lines; and in the building system that solved the problem of gravitational pull by its equipoise of attraction and revulsion, and by its equilibrium of thrusts and counterthrusts.

E. Renaissance, Baroque and Neoclassical Styles

1. Renaissance.—The widely accepted historical view that the Renaissance represented a rediscovery of the beauties of nature and the joys of this world, a rejection of medieval religious authoritarianism in favour of a secular spirit of free scientific inquiry, and a rebirth of classical humanism needs critical reappraisal. More accurately, the movement appears to have been more an evolution than a revolution, more a continuation and intensification of certain trends apparent in late Gothic thought than an abrupt break with the immediate past.

In regard to nature, no more eloquent tribute than St. Francis' "Canticle of the Creatures" (*c.* 1225) or the descriptive passages in Dante's *Divine Comedy* have ever been penned. The acute observation and accurate representation of flora and fauna in late Gothic sculpture, tapestries and manuscript illuminations reveal a de-emphasis of allegory and symbolism and point to a recognition of the realities and beauties of the visible world. The paintings of Duccio and Giotto are evidence of renewed interest in spatial perspective and the presentation of visual data as the eye sees them. Naturalism was thus already highly developed in Gothic art. The Renaissance extended this and gave it a special scientific character.

The Renaissance, in fact, witnessed a partnership between art and science in which sculptors and painters became leaders in seeking a more exact understanding of the physical world. Curiosity about natural phenomena drove artist and savant alike to experimentation and investigation. In order to depict the musculature of the human body more accurately, artists dissected cadavers and made significant strides in anatomy. By applying Euclid's

theorems to diverging and converging lines, artists worked out the principles of spatial representation, perspective drawing and foreshortening. Speculation on optics and the dynamics of light led painters to the discovery of atmospheric perspective and the modeling of figures in light and shadow so as to create the illusion of three-dimensionality. Renaissance man thus was pictured in well-proportioned interior settings that had depth as well as height and breadth. Outdoors, in the midst of living landscape, Renaissance man could gaze about and behold a world created for his delight and enjoyment. Nothing, in short, was too large or small to claim the attention of the inquiring Renaissance mind, and Leonardo da Vinci's notebooks bear witness to the scientific speculation and progress that took place.

During the middle ages the spirit of classical humanism had been kept alive in isolated monastic centres and universities; in Renaissance times it began to flourish once more. God, according to Pico della Mirandola, made man at the close of creation to know the laws of the universe, to love its beauty, to admire its greatness. Man once again became the measure of all things, and nothing human was foreign to the Renaissance artist or his art. Medieval man had thought of himself in such larger contexts as class, family, party or corporation, but Renaissance man became an individual in his own right. In late medieval times Petrarch wrote sonnets to his Laura, and Simone Martini painted her portrait, but Laura was still partially an abstract ideal from the age of chivalry. With Renaissance writers and painters, the subjects of biographies and portraits became flesh and blood. Artists became active competitors for personal recognition. Their patrons likewise sought renown by sponsoring works that bore their names as, for example, the chapels created by Brunelleschi, Masaccio and Michelangelo for the Pazzi, Brancacci and Medici families, respectively.

To enjoy, said Leonardo, is to love a thing for its own sake and for no other reason. The Renaissance artist looked more for the intrinsic value of objects than for their symbolic or allegorical significance. In contrast to his medieval counterpart, the Renaissance artist thought more in terms of the purely aesthetic aspects of his work and less in terms of moral lessons and visual narrative techniques. He was more concerned with modes of presentation and pictorial mechanics than with subject matter as such. He was also more conscious of his mission to create works of art, while his medieval predecessor was content to produce functional objects in which artistic implications were more a by-product than a direct concern.

2. Classicism.—Greco-Roman ideas recur in every century, and it is illuminating to compare Renaissance conceptions of classical art with those of the Baroque and Neoclassical periods. The models each generation chooses from antiquity, the way each century adapts and modifies ancient forms and handles decorative details, the manner in which each period absorbs the classical vocabulary into its expressive language become critical indices to the understanding of each style.

Interest in the antique world during the Renaissance had been limited to certain restricted circles of intellectuals and artists: the Florentine academy, the group around Lorenzo de' Medici and the courts of certain of the popes. Baroque classicism, as exemplified at the court of Louis XIV, was the plaything of an aristocratic class who pictured themselves as Olympian deities with all their mythological trappings and capricious moral behaviour. The Neoclassicism of the revolutionary period had a broad popular base in the solid citizenry of an educated middle class who saw Greece and Rome as the birthplaces of liberty and freedom. Lorenzo the Magnificent, as the head of a small city-state, could envisage himself as the philosopher-king of Plato's *Republic;* Louis XIV, who viewed the antique world through the eyes of an absolute monarch, found his model in Alexander the Great; and the leaders of the American and French Revolutions found precedents for their new governments in the parliamentary forms of the Roman republic.

The extent of knowledge about antiquity varied considerably. During the Renaissance an occasional antique statue was unearthed and caused a stir. In Italy, however, the heritage of antiquity could be seen on all sides, in the extant monuments as well as in the Roman bridges, roads and buildings that were still in use. Not until the late 18th century and the discovery of the ruins of Herculaneum and Pompeii, however, were large-scale excavations undertaken. The Neoclassical period, therefore, had a far more exact knowledge about all aspects of ancient life than was available during the Renaissance or Baroque periods. Speculation about antiquity during the Renaissance was largely an individual affair. During the Baroque, however, the French academies were set up to codify classical principles, uphold canons of proportion and order and enforce rules of symmetry and clarity. In this way the academies acted as a restraining influence on Baroque exuberance and to a certain extent curbed Baroque decorative extravagance. By Neoclassical times, classical archaeology had come to be regarded as a science, and faithful adherence to authentic models was required.

Renaissance and Baroque artists, furthermore, knew antiquity only through Roman eyes, while the Neoclassicists had the advantage of more authentic information about Greek originals. Until the late 18th century, original Greek architecture and sculpture had remained unknown to western artists. At that time Stuart and Revett described and measured the antiquities of Athens; Winckelmann drew a clear distinction between Greek and Roman sculpture; and Lord Elgin brought back his collection of ancient Athenian sculptures to London.

In the Renaissance Botticelli occupied himself with mythological subjects and allegories; Poussin, his Baroque counterpart, evoked nostalgic and elegiac moods with his serene figures strolling through Arcadian landscapes; while the Neoclassicist David desired all aspects of his canvases to be so faithful to antiquity that if a Roman of ancient times should suddenly come to life he would feel at home. In sculpture the Italian Renaissance reaffirmed the expressive power of the nude, revived Roman techniques of bronze casting and created original works animated by the spirit of antiquity. Baroque statuary created new variations on old mythological themes. The Neoclassical sculptors saw living flesh through the marble eyes of antique statuary, and with their pointing machines produced works that adhered closely to classical models. In landscape architecture the gardens of the Italian Renaissance with their fountains, grottoes and statuary, had a dignified formality. Baroque classicism sought to master nature, force it into geometrical patterns and harmonize it with a rational concept of the cosmic order. Neoclassical gardens, however, became highly picturesque with artificially constructed ruins and picturesque accents.

In the early Renaissance Brunelleschi sought the inspiration of ancient Rome in Vitruvius' treatises and in such monuments as the Pantheon. When, however, he built the dome of the Florentine cathedral, he reverted to Gothic vaulting methods. By using Roman decorative detail, his Pazzi chapel achieved a crisp, clear-cut geometrical definition that marked a distinct departure from the medieval concept of infinite space. Baroque architects thought in terms of the correct use of the classical orders, the mathematical proportions of their buildings and the judicious use of antique decorative detail. The Neoclassicists, however, were concerned with the problems of archaeological correctness. Baroque rationalism could never have countenanced the reconstruction of classical buildings for contemporary use. Baroque architects were content to design their "modern" buildings and adorn them with ancient porticoes and Roman decorative motives. The archaeological enthusiasm of the Neoclassicists, however, led to the construction of "ancient" buildings for modern use, and this antiquarianism often resembled a cult of ruins.

F. Romantic and Modern Styles

Though in the late 18th and early 19th centuries Neoclassicism had the full force of officialdom and the academies behind it in France and was still the accepted style in Georgian England and the American Federal period and early republic, it represented

but one tendency of the arts of this time. While Neoclassicism was riding the crest of the popular wave, the Gothic revival was enlisting its partisans; the German "storm and stress" outbursts were reverberating in dramatic, literary and musical circles; the tender emotions were being aroused by the "sensibility" movement in bourgeois novels, plays and genre pictures; interest in the near and far east was adding an exotic dimension to the imagination; and bucolic novels and landscape paintings pointed to the "back to nature" movement. In this battle of styles the pious medieval knight, the noble savage, the idyllic shepherd, the poor but proud peasant competed for popular favour with the dignified Greek and stalwart Roman. Together these new images of man heralded the dawn of romanticism with its repertory of escape mechanisms and its longings for any place but here and any time but now.

In approaching the arts and ideas of the modern world, it is well to keep in mind that at present, as in the past, there are two possible world views. The subjective view is coloured by personal involvement and an accent on emotionalism. The objective view bespeaks logical organization and a cool, detached intellectuality. The subjective side reveals itself in the various facets of expressionism, in which the emotions gain the upper hand, the inner world of neuroses and psychoses is explored and protests against existing conditions in the external world are made. Objectivity in contemporary art finds its outlet in various forms of constructivism such as cubism, futurism, the mechanical style in painting and sculpture and the international style in architecture.

The exponents of expressionism and its variants are little concerned with the world of appearances. Reactions to physical, psychological and spiritual events can be revealed only by looking inward and beholding soul states through the mind's eye. The images on the canvas are altered and distorted according to the intensity of emotion and violence of feeling through which they are viewed. The visual vocabulary used to express such flights of the imagination, neuroses and psychoses includes psychological symbolism, violent visual distortions, conflicting linear directions, clashing colour dissonances and a variety of shock techniques.

From the Renaissance until the end of the 19th century, the pictorial artist was expected to portray the three-dimensional physical world and to describe the objects in it more or less completely from one point of view, that of the spectator. Pictures through their subject matter, literary allusions and narrative content made constant reference to the world outside the picture. In abstract design, natural appearances, as the eye beholds them, play little part; it is a type of analytical vision in which a landscape or still-life composition is simplified to a system of angles, shapes and patches of colour on a two-dimensional surface. Abstract art had its inception in Cézanne's pictorial studies in which he saw nature in terms of such forms as the cylinder, the sphere and the cone. The geometry of the cubists, futurists and practitioners of the mechanical style, based as it is on a dynamic image of the world, is considerably more complex. Vision, in their theory, is a fast-moving, fleeting experience in which the observer sees objects not from a single point of view but simultaneously from many. A picture, therefore, should be presented as a constellation of multivisual viewpoints and in multifocus perspective. In a process of disintegration and reintegration, fission and fusion, the cubists and their successors analyzed, broke up and fragmented their pictorial content, then reassembled it in a new unity, one that lies not in the subject represented but in the picture itself. The nonobjectivists went a step farther in banishing all recognizable objects derived from the external world. They manipulated their abstract lines, swirls of colour and free forms, and the picture becomes both an independent entity and its own referent. *See* also ABSTRACT ART; CUBISM; DADAISM; EXPRESSIONISM; FAUVISM; FUTURISM; IMPRESSIONISM; MANNERISM; POSTIMPRESSIONISM; SURREALISM.

In seeking an understanding of contemporary art, the observer must remember that modern society presents an unusually complex picture, that extraordinary technological advances have invited artists to experiment in many new mediums and that detailed knowledge about the products of past centuries have opened up wider historical horizons than those beheld by any previous period. While formerly an artist lived and worked within a small geographical centre and executed commissions for a few patrons, his modern counterpart addresses his work to a vast, inchoate public, with all its international connotations and multiplicity of social levels. Contemporary artists as well as observers are, to a greater extent than ever before, the heirs of all the ages. Access to vast stores of information can lead either to a stultifying eclecticism in artistic productivity and public taste, or can become a challenge to new creative activity. In one case the dead arts are in danger of burying the living; in the other, the present, without denying its heritage, can assert itself in the face of the past and evolve new mediums and expressive forms.

Since each cultural epoch, century, generation and individual views the world with different eyes, no one concept or image is ever final. All works of art exist in the present, and since new ideas of art are constantly appearing, all such works become links in the chain of evolution of new forms. *See* MODERN ARCHITECTURE; MODERN ART; NINETEENTH-CENTURY ART; *see* also references under "Art" in the Index. (WM. F.)

ART, SOCIETIES OF. The earliest societies of art consisted solely of practising artists and existed chiefly for their mutual protection and to a lesser extent for their social betterment. They had their origins in medieval "lodges," which were groups of craftsmen working together on ecclesiastical building projects; but early in the 14th century painters and sculptors began to secede from the lodges and to attach themselves to guilds. In Florence the appropriate guild came to be the surgeon apothecaries', and a special branch for artists was formed in 1360 with compulsory membership. Earlier, the Florentine Compagnia di San Luca (Guild of Saint Luke) had arisen (*c.* 1339) as a voluntary religious company of artists, but with mainly charitable aims, for its rules (1386) do not mention the practice of art. St. Luke had been chosen as its patron saint in accordance with the 6th-century legend that the Apostle painted the Blessed Virgin's portrait. A similarly named guild also flourished at Antwerp; its earliest surviving records are of 1453.

The guild organization, with its restrictive rules and carefully observed hierarchy, became increasingly irksome to more independently minded artists, particularly when the church ceased to be the unchallenged patron of the arts and when painting came to be regarded more as one of the liberal arts than as a craft—with all the enhanced social status thus implied. The old master-apprentice relationship was slowly replaced by one of professor-student, with the emphasis upon the teaching of knowledge rather than of manual skill. Symptomatic of this change was Lorenzo the Magnificent's "garden school" (or academy) at Florence, founded in 1490 with the sculptor Bertoldo at its head and Michelangelo as its most distinguished student. There the instruction was informal and uncircumscribed by guild rules. Leonardo da Vinci's academy (*c.* 1498), by contrast, was not a teaching establishment, but seems to have been a group of amateurs—a social gathering of men meeting to discuss the theory and practice of art. Similar academies were formed by Baccio Bandinelli at Rome (1531) and at Florence (1550). Nevertheless, the old Florentine guild of surgeon apothecaries and Guild of Saint Luke were only finally vanquished by the advent of Giorgio Vasari's Accademia del Disegno in Jan. 1563, under the patronage of Grand Duke Cosimo de' Medici, who shared with Michelangelo the honour of *capo* (master)—a significant development of the artist's social position. Vasari's *accademia* became the society of leading Florentine artists and the chief centre of instruction for students. But its organization soon began to crack, and in about 1575–78 Federico Zuccaro unsuccessfully attempted to reform it. His ideas were later carried out at Rome when he and Cardinal St. Carlo Borromeo founded the Accademia di San Luca in Nov. 1593. This was the prototype for the modern academy: education took priority with the election of 12 visiting tutors; there were departments of drawing from casts, the antique and the life; prizes were offered, and the members and the president (Zuccaro) were required to present works of their own. Lectures on mathematics and physics were planned but never delivered. After several vicissitudes the Accademia di San Luca became firmly

established by 1635.

The history of academies then became inextricably interwoven with that of art societies: then, too, were sown the seeds of confusion between the definitions of learned society and society of art; for once painting, sculpture and architecture were regarded as the equals of, for example, mathematics, astronomy, rhetoric and poetry, it became necessary to indicate how each branch of knowledge again divided off into separate compartments by the time the highly specialized 20th century was reached. Thus the Accademia della Virtù, Rome (*c.* 1538), was the first archaeological society and the indirect ancestor of such societies as the (British) Society for the Promotion of Hellenic Studies. Societies of this kind obviously have an artistic as well as scientific appeal, but their membership is comprised of enlightened amateurs or professional scholars with few, if any, practising artists.

In the 16th and 17th centuries there appeared in Italy a number of informal, and sometimes semisecret, societies of artists, intended to provide corporate lodgings, studio and life-model facilities, and even mutual physical protection. Some of these clubs or cabals were formed by foreign artists working in Italy. A notorious example was the "Cabal of Naples" organized in the 1630s by Jusepe Ribera and others to persecute north Italian artists who had obtained contracts in the city.

During the 17th century Italy gradually lost the initiative in artistic matters to France. In Paris the Académie Royale de Peinture et de Sculpture, due largely to Cardinal Mazarin's efforts, merged with the old guild organization, the Académie de St. Luc, in Aug. 1651. Ten years later Jean Baptiste Colbert was elected director and in 1666 the Académie de France was founded at Rome. The four-year studentship, "Prix de Rome," followed, and French supremacy in Rome was achieved when the French artist Charles Errard was elected *principe* of the Accademia di San Luca in 1672. An important new development of the academy as an exhibiting society took place in 1667 when an exhibition of students' prize drawings and members' work was held at the Paris Académie. From this was evolved the annual salon of succeeding centuries, which in turn formed the pattern followed throughout Europe during the latter half of the 18th century and after.

In northern Europe the most important academy after that of Paris was Berlin's. Founded by Frederick I of Prussia in 1697 it was part of an ambitious cultural program which included the formation of the University of Halle and the Akademie der Wissenschaften. Both the Berlin academy and that at Vienna (1705, reformed 1725 and 1770) were based on the French pattern. By contrast with those in the wealthy, highly systematized royal states, Flemish and Dutch artists remained within loosely knit guild organizations which hardly interfered in their affairs except to gather annual taxes. In Holland no direct state patronage existed, and the artist had complete freedom of expression. But this meant that he had to paint for an unknown clientele, and so gradually specialized in a particular genre, disposing of his work through a new class of intermediaries—dealers. The old regulating mechanism of guild and state patronage disappeared, and the markets became oversupplied. Most Dutch artists chose to have a second breadwinning occupation. This was the first symptom of an evil that bedeviled 20th-century painting, and one which helped to stimulate the rapid increase in exhibiting societies after about 1880.

The 18th Century.—Paris, Rome, Florence and Bologna were among the most active of 19 academies flourishing in 1720; by 1790 over 100 academies and public schools of art had been formed. Most German princely states possessed private academies, closely followed by Italy; in France provincial academies were subservient to Paris; Spain, Scandinavia, Belgium, the Netherlands and the U.S. also opened new academies. This rapid rise accorded well with the changing taste of the age of reason, an age also characterized by revived interest in antiquity, classical ruins and literature. Equally important was the practical value of these schools as stimulants to overseas commerce resulting from their raising of the general standard of a nation's products. A few exceptions to this revived mercantilism were Rome, Florence, London, Madrid, Turin and Düsseldorf. Rome and Florence had a strong ancient tradition; in England art education remained in private hands and was generally conservative. Even the (now Royal) Society of Arts for the Encouragement of Arts, Manufactures, and Commerce in Great Britain (1754) did not provide an art school, and it had been anticipated by the Dublin society for "improving husbandry, manufactures and the useful arts and sciences" (1731) and the Foulis academy, Glasgow (1753).

Sir Godfrey Kneller's academy held its first meeting on St. Luke's day, Oct. 18, 1711, and soon after Kneller's death in 1723 this private art school was continued by Sir James Thornhill, who was himself succeeded by his son-in-law William Hogarth in 1734. Hogarth then fused the old St. Martin's Lane academy (begun 1720) with Thornhill's property and by 1750 it had become the chief English academy. But life drawing was its only function, and a more general artistic demand was satisfied after the foundation in 1734 of the Society of Dilletanti by a group of gentlemen travelers and amateur *cognoscenti*. In 1768 the Royal academy (*see* ACADEMY, ROYAL) came into being, and a special feature of it was the great importance attached to annual exhibitions. Experience had shown that its precursor, the Society of Artists of Great Britain (founded 1760, granted royal charter 1765), found such exhibitions a sure and cumulative source of income; so also did the academy, which soon became financially (and therefore politically) independent of royal patronage.

By 1790 the chief function of most academies was as art schools, whereas formerly they had been select groups of especially competent men. An interesting reversion to the function of the Medicean and Vasarian academies had taken place, for academies were educational rather than social institutions. Just as they had spread rapidly across Europe during the second half of the 18th century so also did they gather a small but vociferous opposition. Jean Jacques Rousseau, Edward Young, Goethe and J. G. von Herder led the Romantic school in philosophy and letters, J. L. David and A. J. Carstens in painting. Their chief attack was made against the universal rules prescribed by academicians for the comprehension and instruction of creative genius. Academies were regarded as sickly things only capable of perpetuating the mediocre, a view also held by Voltaire and the Encyclopaedists. But Jacques Louis David, in his struggle against the Académie Royale, failed to change any part of its fundamental structure. Although in 1793 he broke with it and replaced it with a Commune des Arts which abolished all rival organizations, its successor, the Societé Populaire des Arts, renewed contact with surviving members of the old Académie Royale, reopening in 1795 as the École des Beaux-Arts (for art instruction) which left social functions to the fine arts section of the Institut de France. This latter was named the Académie des Beaux-Arts by Louis XVIII in 1816.

Nineteenth and Twentieth Centuries.—After about 1805 there was a bewildering proliferation of art societies, the majority of which were, originally at least, antiacademic in intention. This rapid growth also reflects 20th-century anarchy and increasing specialization in the figurative arts.

At first, the most effective antiacademic movement centred around the German painters Johann Friedrich Overbeck, Franz Pforr, Peter von Cornelius and Friedrich Wilhelm von Schadow who formed a Brotherhood (later "Order") of St. Luke, about 1807–08, afterward traveling to Rome where they lived and worked in the deserted monastery of S. Isidoro. The Nazarenes (as they were nicknamed) believed that the defects of an academy —mechanical routine and slick drawing formulas—could be avoided by a return to the more intimate teacher-pupil relationship characteristic of a medieval workshop. Cornelius returned to Germany in 1819 to direct the Düsseldorf academy, but both there and at Munich, where he moved in 1824, he proved a poor organizer and it was left to his successor, Schadow, to introduce teaching reforms in 1826. The most important of these derived from an idea already practised in France by David; *i.e.*, one professor, instead of 12 visiting teachers, to supervise 30 or 40 pupils drawing and painting from casts and life.

Patronage began to undergo radical changes: fewer works were commissioned directly from the artist, and by the middle of the century it had become increasingly important for artists to find

exhibition space in order to attract buyers. Academies could supply this need only partially and were therefore highly selective; since quality was not always the sole basis of selection their enemies had further cause for complaint.

In England the Free Society of Artists held exhibitions from 1761 to 1783, and the (now Royal) Society of British Artists was founded in 1823 as a revival of the old Royal Society of Artists of Great Britain (1760–91). Between 1850 and 1860 the National Institute of Fine Arts catered for many minor painters who seldom exhibited elsewhere. More specialized institutions were the (now Royal) Society of Painters in Water Colours (1804), the Royal Institute of Oil Painters (1883), the Royal Society of British Sculptors (1904), the Royal Society of Painter-Etchers and Engravers (1880) and the Pastel society (1898). The foundation of the New English Art club in 1885 marked a major secession from the Royal academy, only partially healed after several leading members were later readmitted. A second upheaval followed the first Postimpressionist exhibition at the Grafton gallery when the London group (at first called the Camden Town group) was founded (1912). Other independent groups were the Society of Twelve (1904–15), which included Charles Conder, William Orpen, Alphonse Legros and D. Y. Cameron; the short-lived Young Painters' society (1930); the Allied Artists' association (1908–20), which held annual salons at the Royal Albert hall; and the Seven and Five society (1920), which later comprised the nucleus of English abstract painters, some of whom, however, subsequently seceded to Unit One. Indicative of the fierce sectarianism of the 1900s was the formation of the Modern Society of Portrait Painters (1908) and the National Portrait society (1912–21) in rivalry with the older Royal Society of Portrait Painters (1891). Similarly, the Society of Graver-Painters (1910), the Senefelder club (1910) for lithographers and the Society of Graphic Art (1921) supplemented the conservative Royal Society of Painter-Etchers and the (now defunct) International Society of Painters and Engravers (1898). The terms "international" and "national" usually denoted independence and catholicity of outlook: such was the declared policy of the National Society of Painters, Sculptors, Engravers and Potters (1930), of the Artists' International association (*c.* 1943) and the Women's International Art club. The East London group begun in 1929 later became the East End academy, accepting work from amateurs and professionals resident locally. The increased popularity of art, at first largely due to John Ruskin's teaching and facilitated by the increased leisure now more widely enjoyed, was emphasized by the countless amateur art societies active throughout England and Wales. Ireland and Scotland each have their own royal academies (founded 1823 and 1826 respectively) besides numerous independent organizations for professionals and laymen. The state-aided Arts Council of Great Britain (formerly the wartime Council for the Encouragement of Music and the Arts), formed in 1946, must also be mentioned for the help and encouragement it extends to all the arts. In 1950, for example, it sponsored an exhibition of the revived Society of Mural Painters.

The Paris salon was attacked in 1790, and the following year works by all artists (whether academicians or not) were admitted. But it suffered its most serious rebuff in 1863 from the Salon des Refusés, where works by the avant-gardes Edouard Manet, Camille Pissarro, J. A. M. Whistler and Paul Cézanne were shown. The École des Beaux-Arts was reorganized the same year. In 1874 the Impressionists exhibited together as a "Societe anonyme des artistes peintres, sculpteurs, graveurs, . . . etc." Their eighth and last group show was in 1886, two years after the formation of the Société des Artistes Indépendants, which had held its first salon unrestricted by a selection jury. Then in 1890 the official salon suffered schism, and from it grew two separate organizations: Société Nationale des Beaux-Arts and Société des Artistes Français. The latter began to admit the decorative arts on a small scale, but the Salon d'Automne, founded in 1903, especially favoured them. In 1898 the lithographers banded together as the Société des Peintres Lithographes.

Toward the end of the century artists tended to form into small independent groups, united by common ideals but indifferent to the setting up of rigid constitutional machinery. In Paris for example, the *Nabis* ("prophets" or "leaders") used to assemble once a month for dinner at the Restaurant de l'Os à Moelle (Nov. 1888 onward) and soon after met regularly each Saturday at the studio of Paul Ranson. They exhibited together at a private gallery (Le Barc de Boutteville) from 1891 until 1896, as well as sending to the Salon des Indépendants.

Similarly, in 1908 the Cubists banded together as La Groupe du Bateau-Lavoir (13 rue Ravignan, Montmartre); although in 1911 a second group of Cubist painters met at Jacques Villon's studio and founded the Salon de la Section d'Or in an attic (rue Trouchet). The Salon des Surindépendants (founded 1927, and unconnected with the Indépendants), the Salon des Tuileries (1923) and the Salon de Mai afford a cross section of modern French painting. Many young artists of all nationalities and tendencies working in Paris exhibited after 1950 at the annual Salon de la Jeune Peinture held at the Musée d'Art Moderne.

Much the same process of revolt occurred in Germany, Austria, the Netherlands and Belgium. The German school of Impressionists led by Max Liebermann and Max Slevogt organized the Munich Sezession ("secession") in 1894, an example soon copied at Berlin. In Vienna, the Sezession was in 1897 and constituted a landmark in the history of the international *art nouveau* style. In 1905 a group of German painters working in Dresden exhibited together until 1913 as *Die Brücke* ("The Bridge"), which became the centre of the Expressionist school. Cubist doctrine quickly spread from France, and at Munich in 1911, Wassily Kandinsky, Paul Klee and Franz Marc formed *Der Blaue Reiter* ("The Blue Rider") group of German abstract painters; in this year also Piet Mondrian left the Amsterdam St. Lucas group to help found the Moderne Kunstring ("modern art circle") of Dutch abstract artists. Two years later the Erster Deutscher Herbstsalon ("first German Autumn salon") was held in Berlin, and its title betrays its French origin. After World War II the supreme German professional artists' organization was the Bund Deutscher Landesberufsverbände Bildender Künstler. Belgium also had its independent societies such as Les Vingt (1884) and the Salon de la Libre Esthétique, which held its first exhibition in 1896. Le Cercle des Indépendants, Brussels, organized the first Cubist exhibition in Belgium in 1911.

In Italy, the first Venice Biennale was held in 1895 as an international review of current artistic trends, and a similar series of *biennali* at Rome were begun in 1921. Nothing could be more violently antiacademic than the group of Futurist painters whose manifesto was proclaimed at Turin in March 1910. The Fronte nuovo delle arti (1946) led by Renato Birolli and Renato Guttuso was intended as a counterblast to the reactionary Novecento group.

Even as this revolt against academies was taking place, a new awareness of the need for the fine arts to be linked with industrial design steadily increased and the perils of the doctrine "art for art's sake" was realized. In England this movement produced the Art Workers' guild (1884) and the Arts and Crafts Exhibition society (1888, now defunct), from which sprang the Council for Industrial Design and the Rural Industries' bureau. Nevertheless, the Germans were the first to realize the full significance of William Morris' ideas of workshop training for artists and initiated reforms in their industrial schools of art. The Deutscher Werkbund was founded in 1907 as a society of enlightened architects, designers and industrialists, and this prepared the way for Walter Gropius' famous Weimar Bauhaus (1919). There the tradition of the medieval craft guilds was ingeniously fused with modern school instruction and industrial manufacturing processes. In nearly all the chief European countries industrial design organizations developed, usually government-financed and in varying degrees state-controlled.

Direct state control of the arts obtains in both the U.S.S.R. and China. The Mir Iskusstva ("The World of Art," from a magazine so entitled, 1899–1904) group of St. Petersburg centring around Sergei Diaghilev, Léon Bakst, Alexander Benois and K. Somov was discredited after 1917; so also were the Constructivist V. Tatlin and the Suprematists K. Malevich, A. Rodchenko and D. P. Sterenberg, who led the Russian school of abstract paint-

ing until about 1925. The October society which succeeded the Constructivists was denounced as "formalist" (*i.e.*, not "social realist") and was contrasted with the Association of Artists of the Revolution. In 1927 a State Committee for Art Affairs was appointed by the Soviet government to decide and implement the official artistic policy. Soon afterward the Artists' co-operative (Khudozhnik) was formed with a central and branch councils. The co-operative acts as agent; it supplies painting materials, etc., and living accommodations, besides buying, exhibiting or selling work on commission in its chain of galleries throughout the U.S.S.R. These exhibitions are controlled by politico-artistic selection juries. The Moscow Union of Soviet Artists (Moskovsky Soyuz Sovietskikh Khudozhnikov or MOSSKh) is the largest of several provincial groups. The All-China Artists' association was formed about 1950 with headquarters in Peking; its membership consists of artists, critics and art historians. It is divided into four commissions: (1) creative; (2) national artists' research; (3) popularization of art; (4) exhibitions (5 branches). Like its Russian counterpart it makes recommendations about public building decorations, and fixes suitable scales of payment.

Societies for Popular Encouragement and Preservation.—These are largely a 20th-century development, but the British institution (1806–67) acted as both patron and meeting place for artists and connoisseurs, and a similar function was performed by the Burlington Fine Arts club, London (1880–1939). In 1903 the National Art-Collections fund was founded to help national museums acquire art treasures in face of increasing financial competition from wealthy foreign collectors, and in 1910 the Contemporary Art society began similar work for the acquisition of works by modern artists; both have headquarters in London. The Institute of Contemporary Arts, London (1947), also acts as a discussion and exhibition centre for the avant-garde.

Most large European continental museums have organized groups of interested laymen to aid them—for example, the Société des Amis du Louvre, Paris (1897); the Société des Amis des Musées Royaux de l'Etat, Brussels (1907); the Verein des Museumfreunde, Vienna; and the Sociedad Española de Amigos del Arte, Madrid.

Among the British societies of preservation and special study may be listed the National Trust for Places of Historic Interest or Natural Beauty (1895), the Georgian group (1937) for 18th-century architecture and the Society for the Protection of Ancient Buildings, established under William Morris' leadership. Many local preservation societies were formed after 1935 to meet the threat of heavy industrialization and rapid urban development.

(D. L. Fr.)

THE UNITED STATES

The oldest permanent art association in the United States is the Pennsylvania Academy of the Fine Arts, established in Philadelphia in 1805 to provide instruction in the fine arts, exhibit works of contemporary artists and maintain a permanent collection and gallery. Although an Academy of Sciences and Fine Arts had been formed in Richmond, Va., in 1786, the project languished and finally was dropped.

The New York Academy of the Fine Arts was organized in 1802; it existed until 1841 and is said to have provided almost the only art influence in New York for nearly a quarter of a century. In 1825, however, a number of its students formed the New York Drawing association, an independent society presided over by the painter-inventor Samuel F. B. Morse, which in 1828 was incorporated as the National Academy of Design.

The development of interest in art in the United States has been progressive—for the first 100 years undoubtedly slow, but thereafter more rapid, and as the years passed, surprisingly so. It may well be noted that the art movement was largely fostered by laymen. In 1909 the American Federation of Arts was formed to furnish a channel for the expression of public opinion in matters pertaining to art, to maintain a central clearinghouse for art organizations and to undertake educational work for which only a national organization could qualify; with national headquarters in New York city, the nonprofit organization had about 400 chapters in the latter 1950s. Associated with the American Federation of Arts were all of the chief interests in art—practising artists, teachers and art departments in schools and universities, various associations, dealers and private collectors, museums and laymen. To have a central organization, art associations in some states were federated.

Professional Organizations.—Chartered in 1857, the American Institute of Architects, Washington, D.C., held annual conventions from 1867; its membership of more than 10,000 in the mid-1950s was entirely professional. Other architectural organizations include the American group of the Société des Architects Diplômés par le Gouvernement Français (1899) and various local societies. The Archaeological Institute of America (1879) was intended to increase knowledge and disseminate information in its field.

The National Academy of Design, already mentioned, elects to membership painters, sculptors and architects who have attained distinction, holds one exhibition a season and maintains a permanent collection of works by members. It opened its own building in New York city in 1942. (A number of other art societies established headquarters in the building.) The Sculptors' guild (1937), comprising in its membership those of progressive tendencies, holds annual popular outdoor exhibitions. The American Water Color society, New York city (incorporated in 1903), holds annual exhibitions at the National Academy of Design building; the New York Water Color club was amalgamated with that society in 1941. Also important is the Philadelphia Water Color club (1900). In Boston, Baltimore, Washington and other cities water-colour clubs were also established. The American Society of Miniature Painters, New York city (1899), exhibits regularly and similar societies became active elsewhere.

In relatively recent years etching, lithography and wood-block printing had a renaissance in the United States. Of notable importance is the Society of American Graphic Artists, Inc. Organized in 1915 as the Brooklyn Society of Etchers (later called Society of American Etchers and in 1947 named the Society of American Etchers, Gravers, Lithographers and Woodcutters), the organization adopted its present name in 1951. It holds annual exhibitions and promotes international exchanges. Other societies of like nature include the print clubs in Philadelphia (1914), Cleveland (1919) and other cities, which hold frequent exhibitions and sponsor lectures and demonstrations.

To further literature and the fine arts, the American Social Science association organized in 1898 a National Institute of Arts and Letters, New York city, which was incorporated by act of congress in 1913. It comprises, by election, 250 writers, painters, sculptors, etchers, etc. In 1904 it organized, along lines similar to the French academy, an American Academy of Arts and Letters, limited to 50 members.

An organization to advance the artist as well as his art is the Guild of Boston Artists (1914), with artist and associate lay members co-operating in sustaining a gallery for exhibition and sale of members' works. Somewhat similar, the Grand Central Art Galleries, New York city (1923), with the purpose of marketing works of American artists, maintains a continuous exhibition of works of members and also sends out traveling exhibitions. The Society of Medalists, established in 1930 to stimulate interest in medallic sculpture, issues to its approximately 600 members two bronze medals each year.

The alumni associations of the leading art schools are closely allied with the professional art organizations.

Groups Associated With Museums.—The members of the Metropolitan Museum of Art, New York city, numbered approximately 12,000 in the mid-1950s. The Museum of Fine Arts, Boston, formed in the same year (1870) as the Metropolitan museum, likewise relied a great deal on funds from supporting members (2,300). The Art Institute of Chicago (1879), with a membership of about 17,200, depended to a greater extent on wide popular support. The Toledo Museum of Art (1901) was long supported by an associate membership; the Buffalo Fine Arts academy (1862) was the parent of the Albright Art gallery; the Cincinnati Museum association (1881) acquired a gallery through gifts in

1887 and thereafter the art museum was supported by private contributions. The Art Association of Indianapolis (1883) acquired a gallery, now the John Herron Art institute; the museum was dedicated in 1906 and remodelled in 1941. The Minneapolis Society of Fine Arts (1883) opened the Minneapolis Institute of Arts building in 1915 and made additions in 1927. The Friends of the Institute (1922) co-operate in building up its collections and broadening its influence. Various "Friends of Art" groups were formed in relatively recent years.

Art museum heads organized the Association of Art Museum Directors, established in 1916, and the Western Association of Museum Directors (1921). The American Association of Museums, with headquarters at the Smithsonian institution, Washington, D.C., was established in 1906 and incorporated in 1920. *See* also MUSEUMS AND GALLERIES.

Art and Industry.—Probably the first organization in the United States to recognize the need of relating art to industry was Cooper union (*q.v.*), in New York city (1859). The handicrafts have largely been fostered by societies especially organized for that purpose, such as the Society of Arts and Crafts of Boston (1897), which set a high standard of endeavour and has maintained a salesroom successfully for many years in Boston and New York city; the society became a member of the Massachusetts Association of Handicraft Groups, established in 1945. The Detroit Society of Arts and Crafts (1906), with lay and professional members, brought to the United States notable works by foreign craftsmen.

More intimately associated with industrial art are such organizations as the Art Directors' club, New York city (1920). Members of businessmen's art clubs of Chicago and other cities turned to art for recreation rather than as a vocation.

Civic Associations.—The American Planning and Civic association (1904), a national organization with headquarters at Washington, D.C., and several hundred affiliated organizations throughout the country, embraces city planning, village improvement, protection of scenic beauty and safeguarding of highways in its objectives. Somewhat akin in purpose is the American Society of Landscape Architects (1899), with headquarters in Boston, Mass., whose chief aim is the support of professional ideals in the practice of landscape architecture as an art, and whose concern is mostly that of design in city and regional planning and the design of private and institutional parks and grounds. There are also numerous art commissions, for example, the National Commission of Fine Arts, Washington, D.C. (established by an act of congress in 1910), appointed by the president with the consent of congress and comprising an advisory body of experts, serving without pay, to which are referred designs for public buildings, monuments, improvements of public lands, etc.; and the Art Commission of Philadelphia (formerly the Art Jury, 1907), intended to safeguard municipal authorities against artistic blunders and secure maximum civic beauty. The Municipal Art Society of New York city was established in 1892 as a private organization for the development of civic art.

School Organizations.—School art teachers organized the Eastern Arts association (established in 1910), the Western Arts association (1893) and the Southeastern Arts association (1930). The National Art Education association was organized as a department of the National Education association in 1933. The College Art Association of America (1912) is made up of teachers of art in colleges. The School Art League of New York city (established in 1909), composed of laymen, art teachers and pupils, fosters art education in the public schools of that city. The Chicago Public School Art society (1894), chiefly occupied with placing fine prints and paintings by American artists in Chicago schools, also was instrumental in securing better design for school buildings and decoration for schoolrooms.

See also ACADEMIES.

See Dorothy B. Gilbert (ed.), *American Art Directory* (1958), which contains a complete list of art societies and similar organizations in the United States and a report on each; Nikolaus Pevsner, *Academies of Art* (1940). (L. ME.; X.)

ARTA, capital of Arta *nomos* (department) of Greece in the region of Epirus, on the site of the ancient Ambracia (*q.v.*), stands on the left bank of the Arachthus (Arta or Arakhthos) river, and is surrounded with orchards of orange, lemon and citron. Pop. (1961): town, 16,899; *nomos* (1961) 82,630. Arta came into existence after the destruction of the nearby Roman city of Nicopolis Actia by the Bulgars in the 11th century and became a provincial city and bishopric of the Byzantine empire. In 1083 it was seized by the Normans; and after the fourth crusade (1204) it became the capital of the Greek despots of Epirus, from whom it passed to the Orsini family of Cephalonia in 1318. Subsequently it was under Serbian, Albanian and again Italian rule, before falling to the Turks in 1449 who called it Narda. In the 16th and 17th centuries it was noted for its Greek schools. In 1688 it was taken by the Venetians, and in 1798 by Ali Pasha of Iannina. It was several times fought over during and after the Greek War of Independence; but in 1881 it was ceded to the Greeks, and after the Balkan War of 1912 was incorporated with southern Epirus in the kingdom of Greece. It was occupied by German troops from 1941 to 1944.

There are remains of a Byzantine fortress on the ancient acropolis, several churches and monasteries dating from the period of the despotate (13th century), notably the church of the Panagia Parigoritissa (Our Lady of Consolation), and a 17th-century hump-backed bridge over the river, which forms the theme of a well-known Greek folk song. Arta is now the seat of a metropolitan bishop. Woolens, cottons and embroidery are manufactured; and there is trade in cattle, wine and spirits, tobacco, fruit, hides and grain. (D. M. N.)

ARTA, GULF OF (AMBRACIAN GULF; GULF OF AMVRAKIA or mod. Gr. AMVRAKIKOS KOLPOS), an inlet 20 mi. long and 12 mi. wide, is on the west coast of Greece, where the *nomos* (department) of Arta meets that of Aetolia. It is terminated to the west by the composite limestone peninsulas of Preveza on the north and Aktion on the south. The gap between the two, the straits of Preveza, provides its only outlet to the sea. These straits, little more than half a mile wide, are floored with very shallow flats of sand and gravel. On their north side is the small port of Preveza. The north shore of the gulf is formed by the combined delta of the Louros and Arakhthos rivers, and is a mosquito-ridden tract of marshes and lagoons; the south shore is traced by broad bays alternating with wooded rocky headlands. The arterial road from Arta to Agrinion skirts the eastern shore of the gulf. (WM. C. B.)

ARTABANUS ("protector of right"), an Iranian name the later form of which is Ardaban. It was borne by a number of Persian princes and nobles and by Parthian kings. The following are the most important:

1. ARTABANUS (6th–5th century B.C.), the brother of the Persian king Darius I and, according to Herodotus, the trusted adviser of his nephew Xerxes. Herodotus states that he warned Darius not to attack the Scythians and predicted to Xerxes his defeat by the Greeks. Xerxes sent him back to govern the empire during his Greek campaign.

2. ARTABANUS (d. 465 or 464 B.C.), minister of Xerxes, whom he murdered in 465 B.C. According to Aristotle, he had previously killed Xerxes' son Darius and feared that the father would avenge him; according to Ctesias, he killed Xerxes first and then pretended that Darius had murdered him and instigated his brother Artaxerxes I to avenge the parricide. Artabanus was in control of the Persian state for seven months and was recognized as king by Egypt, but was then defeated and killed by Artaxerxes.

3. ARTABANUS (fl. 465 B.C.), satrap of Bactria, who revolted against Artaxerxes I, by whom he was defeated in two battles.

4. ARTABANUS I (reigned *c.* 211–191 B.C.), king of Parthia, also known as Arsaces II, knowledge of his personal name depending on a single source. In 209 he was attacked by the Seleucid king Antiochus III of Syria, who took Hecatompylos and Syrinx in Hyrcania, but finally concluded a treaty with Artabanus. After 206 the latter lost much territory to Euthydemus of Bactria.

5. ARTABANUS II (reigned *c.* 128–124/123 B.C.), king of Parthia, successor of his nephew Phraates II. Saka invaders then occupied much of Parthia's eastern territories, and Artabanus died of a wound received fighting the "Tochari" in the region of Bactria.

6. Artabanus III (reigned *c.* A.D. 12–*c.* 38), king of Parthia, an Arsacid through his mother, with family links with the Dahae. King of Atropatene, he made a first bid for the Parthian throne in A.D. 9 or 10, against the romanized Vonones, and was proclaimed king in Ctesiphon *c.* A.D. 12. Vonones fled to Armenia, where he secured the throne, but was forced to abdicate through pressure from Artabanus in A.D. 15 or 16. The Roman emperor Tiberius set Zeno, son of the king of Pontus, on the Armenian throne in A.D. 18. During the first part of Artabanus' reign there was peace with Rome, and there is therefore little information for this period. He was apparently a strong king, faced with internal unrest. Two Jewish rebel barons in northern Babylonia are known from Josephus to have been recognized by him as vassal kings. A letter of his to the magistrates of Susa (A.D. 21) survives in an inscription there.

On the death of Artaxias III (Zeno) of Armenia (A.D. 34), Artabanus set his son, known only as Arsaces, on the Armenian throne. Two Parthian nobles, restless apparently at Artabanus' assertion of central authority, applied at this time to Tiberius for a king from among the descendants of Phraates IV. Tiridates III arrived in Syria in A.D. 35 and was set on the Parthian throne, by use of arms and bribery, by the Roman general L. Vitellius. Arsaces of Armenia was assassinated at the beginning of the campaign, and was succeeded by a Roman nominee, Mithradates of Iberia. Artabanus withdrew to Hyrcania, but, summoned by the anti-Roman party, returned within a year, with support from the Dahae and the Saka, and recovered his throne. He made a treaty with Vitellius in A.D. 37. The struggle had evidently weakened Parthia internally, and at this time large areas and some of the great commercial centres appear virtually independent of the crown. Discontent almost at once drove Artabanus into flight again. He took refuge with his vassal, Izates II of Adiabene, while a certain Cinnamus occupied the Parthian throne. Artabanus was restored by negotiation, but died *c.* 38.

7. Artabanus IV (fl. A.D. 80), a pretender to the Parthian throne, who gave shelter to a pseudo-Nero in Parthia in A.D. 79 and who struck coins at the Seleucia mint in A.D. 80–81. He failed to maintain himself against Pacorus II.

8. Artabanus V (reigned *c.* A.D. 213–224), the last Parthian king. The younger son of Vologaeses IV, who died in 207 or 208, he was ruler of Media when he rebelled against his brother, Vologaeses V, *c.* 213. By 216 he had apparently extended his power over Mesopotamia, although Vologaeses continued to strike coins at the Seleucia mint till 222 or 223. The Roman emperor Caracalla, who claimed to have engendered these disputes to weaken Parthia, attacked in 216, ravaging much of Media and desecrating the Parthian royal tombs at Arbela. In 217 Artabanus counterattacked; Caracalla was assassinated, and his successor Macrinus, defeated at Nisibis, made peace with heavy indemnities. Meanwhile, however, Ardashir the Sasanian, who had begun his rule as petty king in the province of Persis in 208, had been steadily extending his domains and winning Iranian allies against Parthian overlordship. Revolt became general and led to the death of Artabanus in battle against Ardashir in 224. *See* Parthia; Persian History. (Ed. M.; Ma. B.)

ARTAXERXES, the Greek form of Old Persian Artakhshathra, the name borne by three kings of the Achaemenid dynasty of Persia. For Sasanian kings who bore a later form of the same name *see* Ardashir.

Artaxerxes I, surnamed in Greek Macrocheir, "Longhand" (in Latin Longimanus), reigned from 465 to 424 B.C. A younger son of Xerxes, he was raised to the throne by the commander of the guard, Artabanus, the murderer of his father. A few months later he slew Artabanus in a hand-to-hand fight in the palace. The authentic account of his cupbearer Nehemiah shows him as kind and good-natured, but he had a vein of weakness and was much under the baneful influence of his mother Amestris. His reign, though on the whole peaceful, was disturbed by several insurrections. It began with the revolt of his brother, the satrap of Bactria, quickly suppressed. More dangerous was the rebellion of Egypt under Inaros, who received assistance from the Athenians. Persian rule was restored by Megabyzus, satrap of Syria, after a prolonged struggle (460–454). Megabyzus guaranteed Inaros' life and when Artaxerxes yielded to the importunity of Amestris and permitted the execution of Inaros, Megabyzus himself rebelled. In 448 the war with Athens was ended by the "peace of Callias," by which Persia renounced its claims on the Greek cities of Asia Minor which were under Athenian rule, while Athens bound itself not to attack Persian territories. In the Samian and Peloponnesian wars, Artaxerxes remained neutral. Toward the Jews he pursued a tolerant policy, permitting Ezra to return to Jerusalem in 458 and appointing Nehemiah as governor of Judaea in 445. His building inscriptions at Persepolis record the completion of the throne hall of Xerxes. A number of alabaster vases from Egypt, plausibly attributed to his reign, bear his name in Egyptian hieroglyphs, in addition to a trilingual cuneiform legend (Old Persian, Elamite, Akkadian). Many tablets dated to his reign have been found at Nippur and a few others elsewhere in Babylonia.

Artaxerxes II, surnamed in Greek Mnemon, "the Mindful," the son of Darius II, reigned from 404 to 359 or 358 B.C. Although personally courageous, his acts reveal him as weak, faithless to his friends and dependent on his favourites and harem, especially his mother Parysatis. When he mounted the throne, the power of Athens had been broken in the Peloponnesian War (*q.v.; and see* Greece: *History*), and the Greek towns of Asia Minor were again subjects of the Persian empire. In 404, however, Artaxerxes lost Egypt as the result of the revolt of Amyrtaeus, and in the following year his brother Cyrus (*q.v.*), secretly favoured by Parysatis and by Sparta, began preparations for his rebellion. Although Cyrus was defeated and killed at Cunaxa (401) this rebellion had dangerous repercussions, for it not only demonstrated afresh the superiority of the Greek hoplites but it made the Greeks feel that Persia was accessible. Greek mercenaries became indispensable both to the king and to the satraps, who thereby gained the means for attempting successful rebellions, into which they were provoked by the king's weakness and by the continuous intrigues between the Persian magnates.

In 400 B.C. Sparta broke openly with Persia and sent aid to the Ionian cities. During the next five years Spartan armies achieved considerable military success in Asia Minor. A naval counterstroke, however, was being prepared by Pharnabazus, satrap of Hellespontine Phrygia, who, with the help of Evagoras of Salamis in Cyprus and the Athenian admiral Conon, destroyed the Spartan navy at Cnidus (394) and thereby gave the Persians mastery of the Aegean. This victory enabled the Greek allies of Persia (Thebes, Athens, Argos, Corinth) to carry on the Corinthian war against Sparta, which was forced to withdraw from Asia Minor. It soon became evident, however, that the only people to gain by the war were the Athenians, who began to revive their old imperial policy (*see* Delian League) and to ally themselves with the Greek cities in Asia, with Egypt and with Evagoras who, in defiance of Persia, sought to seize the whole of Cyprus. In consequence, when Antalcidas went to Susa in 388, Artaxerxes was ready to conclude peace with Sparta. In 386 Athens was compelled to accept the settlement known as the "King's peace" or the "peace of Antalcidas." By this Artaxerxes decreed that all the Asiatic mainland and Cyprus were his; Lemnos, Imbros and Scyros were to remain Athenian dependencies; all the other Greek states were to receive autonomy; and the terms of the peace would be enforced by Persia. After the peace Evagoras was deprived of his conquests but recognized as king of Salamis (380).

Elsewhere Artaxerxes met with less success. Two expeditions against Egypt (385–383 and 373 B.C.) ended in complete failure and in the same period there were continuous rebellions in Asia Minor. Pisidia, Paphlagonia, Bithynia and Lycia threw off the Persian yoke and Caria became virtually independent. There were also wars against the mountain tribes of Armenia and Iran, especially against the Cadusians on the Caspian sea.

By the "King's peace," Persia had become the arbiter of Greece and in the following wars all parties, Spartans, Athenians, Thebans and Argives, continually applied to Persia for a decision in their favour. After the Theban victory of Leuctra (371 B.C.), Pelopidas went to Susa in 367 and restored the old alliance between Persia and Thebes. Persian supremacy, however, was based on

Greek discord. Shortly after the edict by which Artaxerxes proclaimed his alliance with Thebes and the conditions of the general peace which he intended to impose upon Greece, his weakness became apparent. From *c.* 366 all the satraps of Asia Minor were in revolt, in close alliance with Athens, Sparta and Egypt, and the king could do little against them. The satraps, however, were divided by mutual distrust, and the rebellion was finally put down by a series of treacheries, though some of the rebels retained their provinces. When the long reign of Artaxerxes came to an end in 359 or early in 358, Persian authority had been restored over most of the empire, but Artaxerxes himself had done little to obtain this result.

Under Artaxerxes an important change took place in the Persian religion. Berossus states that the Persians did not worship images of the gods until Artaxerxes II set up the image of Anahita in Babylon, Susa, Ecbatana, Persepolis, Bactra, Damascus and Sardis; and whereas all former kings name only Ahura Mazda, inscriptions of Artaxerxes from Susa and Ecbatana also invoke Anahita and Mithra. These two latter deities belonged to the old popular religion of the Iranians, but had been neglected by the true Zoroastrians till Artaxerxes introduced them into the official worship.

Artaxerxes III came to the throne between Nov. 359 and April 358 and died in 338 or 337 B.C. The son of Artaxerxes II, he was called Ochus before he succeeded his father. The chronographers generally retain the name Ochus for him, and in the Babylonian inscriptions he is cited as "Umasu, who is called Artakshatsu." He was a cruel but energetic ruler. To secure his throne he put to death most of his relatives. In 356 he ordered all the satraps to dismiss their mercenaries. Most of them obeyed; Artabazus of Phrygia, who tried to resist and was supported by his brothers-in-law, Mentor and Memnon of Rhodes, was defeated and fled to Macedonia. Athens, whose general Chares had supported Artabazus, was forced by threats to conclude peace and to acknowledge the independence of its rebellious allies (355).

Artaxerxes then attempted to subjugate Egypt, which had remained independent since 404. The first attempt failed (351 B.C.) whereupon the Phoenician towns and the princes of Cyprus rebelled. At the beginning of 345 the king collected a great army in Babylon and marched against Sidon, which the local king, Tennes, betrayed to him. Sidon was burned and Tennes put to death, but Mentor of Rhodes, who had also helped in the betrayal of Sidon, rose high in the king's favour and entered into a close understanding with the eunuch Bagoas, the king's favourite. Artaxerxes then advanced on Egypt with a great land and naval force and, at Pelusium, defeated the pharaoh Nectanebo, who fled to the south (343). A Persian satrap was placed over Egypt; the walls of its cities were destroyed; its temples were plundered; and Artaxerxes is said to have killed the sacred Apis bull with his own hand.

After the king's return to Susa, Bagoas ruled the court and the upper satrapies, while Mentor restored the authority of the empire throughout the west. He deposed or killed many Greek dynasts, among them Aristotle's patron Hermias of Atarneus, who had friendly relations with Philip of Macedonia (341 B.C.). When Philip attacked Perinthus and Byzantium (340) Artaxerxes sent support to those cities, enabling them to withstand the Macedonians. In 338 or 337 Artaxerxes, with his elder sons, was killed by Bagoas, who raised the king's youngest son Arses to the throne. See Persian History. (Ed. M.; J. M. M.-R.)

ART EDUCATION, referring to the visual arts, may be defined in two ways: as the training of potential or actual professional artists; and as the instruction given to school children, students and adults, the purpose being enjoyment, enrichment of life or psychological benefit. Instruction in art is given in the public and private schools, from the pre-elementary through the secondary level; in most colleges and universities; in private academies or schools of art, representing almost all levels of skill; in art galleries and museums; by professional artists giving individual lessons to single pupils; and privately or semipublicly by numerous organizations such as labour unions, youth clubs, fraternal organizations, and so forth.

Until the 17th century artists, like other craftsmen, learned their craft by apprenticing themselves to practising professional artists. Then in France were founded the Académie Royale de Peinture et Sculpture and the École Nationale des Beaux-Arts (*see* Beaux-Arts, École des). The former established the form of art education in Europe for many generations. Italian academies of art were established before the 17th century. The movement for art training in general education was largely a product of the 19th century. (X.)

UNITED STATES

History and Development

Early History.—From the 17th century through the early 19th, the visual arts had little place in American public schools and universities. The student who sought to be an artist learned by assisting an older artist, by taking private lessons or by going to Europe for academic training. A Philadelphia private school, established in 1791, became in 1805 the Pennsylvania Academy of Fine Arts. Drawing was introduced into the public schools of Boston, Philadelphia and Baltimore in the 1840s. In a few eastern colleges, professors of Latin and Greek were showing their classes pictures of classical sculpture and architectural ruins.

From such beginnings, U.S. art education expanded during the 20th century along the following lines: (1) academies and courses for the practice of the arts, sometimes called "creative art" or "studio courses," dealing with the technical use of materials and instruments such as paints and brushes, clay and looms; (2) courses in the appreciation of the arts—in perception, understanding, criticism and evaluation; (3) aesthetics—theories and principles of art; (4) courses in the history of the arts, arranged chronologically; (5) courses in art education—the training of prospective teachers of the arts.

Practice of Art.—The first of these, devoted to practice, is most extensive in the lower grades, for young children from the nursery school on. By the early years of the 20th century it was generally recognized that all young children should have an opportunity to use their hands and minds in manipulating art materials. There were lingering prejudices against art education for boys as a useless, effeminate frill, and for girls as dangerously Bohemian; but these attitudes disappeared as art became a flourishing, respected and occasionally well-paid field.

Art Appreciation.—Art appreciation won a place in the curriculum more slowly. Many practical-minded school administrators assumed that anyone could appreciate art simply by looking at it. The public was slow to realize the difficulty of perceiving and understanding the subtle, complex forms and detailed interrelations within a great work of art. On the college and university level, there were educators who derided the study of appreciation on the ground that "good taste" was something inborn, which could not be taught. They preferred rather to stress historical facts in college courses on the arts. The aim in teaching art appreciation shifted gradually away from urging students to admire certain things and toward developing their powers of perception and evaluation. The new emphasis in art itself on form and design, as opposed to storytelling and sentiment, led to a similar emphasis on form and design in the appreciation and evaluation of art. It was recognized that art appreciation also involved the ability to understand meanings, such as those of symbolic images in medieval painting, sculpture and architecture, as well as the ability to criticize and evaluate. The young child cannot be expected to like and enjoy the same kinds of art as an adult connoisseur, but even in the lowest grades children can discuss their likes and dislikes open-mindedly.

History of Art.—It was not until 1874 that art history was systematically taught in an American college. The place was Harvard and the teacher was Charles Eliot Norton, whose aim was to inspire his students "with love of things that make life beautiful and generous." His staff gradually was increased and (after 1895) aided by the resources of the Fogg museum. Allan Marquand went to Princeton in 1882, founded its department of art and archaeology, and lectured with slides and photographs on Italian art. Other pioneers in the teaching of art history were Charles R. Morey, Frank J. Mather, A. Kingsley Porter, Howard C. Butler

and Paul J. Sachs. By 1880 the Chautauqua Literary and Scientific circle in Chautauqua, N.Y., was teaching art history and appreciation through lectures and correspondence. The Metropolitan Museum of Art in New York began giving lectures in 1872, and in 1907 appointed Henry W. Kent as the first museum instructor. During the next few years, the art museums of Boston, Chicago, Cleveland, Toledo, Detroit, St. Louis and Baltimore were outstanding for their teaching of art history in galleries and lecture halls. By mid-20th century about 900 courses on art history were being taught in U.S. colleges and universities.

Colleges offer introductory courses on general history of art, followed by specialized courses on particular periods. The earliest courses were limited to the Egyptian, Classic, Gothic and Renaissance art of the occident. Modern textbooks and college catalogues show a great increase in the range of nations and periods covered, and much interest is shown in the interconnections of periods and styles within the general flow of cultural history, and in relations between art and other phases of cultural history.

Aesthetics.—The systematic study of aesthetics, including the philosophy, psychology and sociology of art, was still later in developing. Ralph Waldo Emerson made New England philosophically conscious of art and beauty, and G. L. Raymond published an important series of books on comparative aesthetics in the 1890s. A concerted and rapidly expanding movement to establish it as a college subject and a field of scholarship began in 1941 with the founding of the *Journal of Aesthetics and Art Criticism*, followed by the establishment of the American Society for Aesthetics a year later.

The emphasis in aesthetics has shifted from abstract discussions of beauty and value toward an empirical, inductive study of the arts and related modes of experience. Aesthetics tends to assume more and more the aims and methods of a psychological and social science, drawing its data and hypotheses in large part from these older sciences; in part from the direct observation, analysis and comparison of works of art themselves to discover the nature and varieties of form and style. Advanced systematic studies of the history and theory of art are carried on principally in large universities and graduate schools, but they have had a profound influence on the training of teachers of art and hence indirectly on the teaching of art in the lower grades. (*See* also AESTHETICS, HISTORY OF.)

Later Trends in Art Instruction.—Policies in art instruction have been deeply influenced by events in the visual arts. From the Impressionist movement of the 1870s onward there was a growing trend toward nonrealistic styles in painting and sculpture. Postimpressionist movements introduced more alteration of natural shapes, proportions and colours; realistic perspective was altered and the natural shapes of things were freely varied in the interest of design or emotional expressiveness.

These trends were violently attacked by conservatives, but by the second quarter of the 20th century the right of the artist to represent nature with such independent alterations had been fairly generally conceded. These trends in art were influenced also by the late-19th century discovery and revival of many exotic and primitive styles, such as those of African sculpture and prehistoric cave drawing.

There was also a trend toward specialized experiment in the arts; *e.g.*, toward exploring the effects of divided colour in Impressionism or pure, flat, contrasting areas of colour in some of the Postimpressionists; toward geometrical form in Cubism; and toward suggestions of movement and temporal sequence in Futurism. Abstract or nonrepresentational painting was widely taught and produced. The art of children was discovered and admired as something possessing independent value both for the child and for the mature admirer. Child art, when not much influenced by adults, was found to have a spontaneous charm often lacking in the work of older students and also to possess educational value in helping the child to think out and consciously express his inner life and his experience of the visible environment.

Philosophical trends in U.S. thought also influenced art education, notably the pragmatism, instrumentalism and empiricism of such leaders as William James and John Dewey. The trend was toward a greater respect for the practical and the tangible in art and life and toward a technological spirit in the arts.

Prosperity before and after the depression of the 1930s turned a stream of U.S. wealth into art institutions. It also helped to develop many new careers in the arts for young people, who could choose among hundreds of related design occupations in industry and commerce or find work in magazine and book publication, photography, motion pictures, radio, stage designing and television, art museums, journalistic art criticism and teaching—all within the general field of visual arts.

Art education itself broadened to include preparation for these new careers. Academies introduced courses in industrial and commercial design. Some colleges established courses in television and stage production, drawing upon painters for stage design and costume sketches. The great increase in numbers of persons actively practising careers in the arts led to the establishment, in the early 20th century, of many national professional organizations such as the National Art Education association, the College Art association, the American Association of Museums, the American Society for Aesthetics and the Committee on Art Education. These helped to raise standards and to advance discussion and planning. Some co-operated with international organizations such as the United Nations Educational, Scientific and Cultural organization.

CONTEMPORARY LIFE

Elementary and Secondary Schools.—In public and private schools there was a tremendous rise during the early 20th century in the number of courses on art offered at all age levels. In the lower grades there is less departmentalization, and the classroom teachers commonly handle all subjects including the arts, sometimes with the aid of an occasional visit from a supervisor or special teacher. An increasing number of states require all prospective elementary schoolteachers to take some courses in art, but the amount thus required is so small that highly qualified art instruction is not always to be found in the elementary schools. Much is left to the individual teacher's taste and initiative. What the elementary art lesson lacks in technical skill, however, it may gain through better integration with other subjects. In the higher grades, in junior and senior high schools, the curriculum in both public and private schools is more departmentalized, and a given school may or may not teach art; an individual student may or may not elect to take it.

Because of new distracting interests, including college and vocational requirements, more and more students drop the subject of art as they advance in school. Colleges are slow to grant entrance credit for secondary school work in the arts, partly because of the difficulty in evaluating it. In large cities special secondary schools commonly are set up for those interested in manual or technical training in the arts, and the high schools that specialize in college entrance preparation are more likely to offer courses in art history and appreciation.

A serious fault in U.S. art teaching is lack of continuity from grade to grade. There is little agreement or common practice on the sequence of steps from the fundamentals to higher levels. After a good start, a student may abandon all art study for three or four years, then have to begin all over again. Teachers cannot take it for granted that his previous courses in art covered any particular set of facts, skills or experiences.

There also is doubt and disagreement as to goals and standards of value. Some teachers hold to the value of a sound foundation in drawing from life or from sculptural casts, in realistic modeling of anatomy and in accurate perspective. Others, claiming to express the modern age, consider such traditional training worthless, calling for complete freedom for every student and artist to express himself and paint as he wishes. The basic issue is between academic and free expression methods, between strict discipline and the newer, progressive education. The decline in prestige of the academic method has been a result not only of theoretical argument but also of the undermining of the academic method in practice, through the great success of many contemporary artists who had no academic training or formal art educa-

tion, or who completely abandoned traditional styles.

The conflict between extremists gradually has been giving way, however, to a moderate educational philosophy, which seeks to preserve the best features of both. Free expression and progressivism achieve their greatest success on the lowest levels of schooling, where it generally is considered best for young children to play freely with materials and to express their impulses spontaneously. Art education in the lower grades has been much influenced by the psychology of child development; it is widely felt that the spontaneous art activity of children should be used as an instrument for their general personality development. In early adolescence it becomes harder to preserve the interest in spontaneous play and self-expression. Educational methods become more systematic, with definite requirements of knowledge and skill. Many older children lose interest in the arts at this period; others, if they are to continue in art at all, want more techniques. They become self-critical and impatient with fumbling; they want to learn how to do a thing correctly. In drawing and painting, many want to know how to represent the figure in action with an illusion of realism. In history and theory, they want definite information and methods of research. The urgent problem of art teachers in junior and senior high schools is to keep alive the continued growth of the child's abilities by providing him with interesting, usable materials and experiences in the practice, appreciation and understanding of art.

In a few metropolitan communities the public-school system has developed an educational museum or audio-visual lending agency, which distributes materials for the study of the arts, including lantern slides and films in colour, together with machines for projecting them. In a few school systems, the use of these materials is correlated with radio lessons. At a given time, an art teacher in the central radio studio may broadcast a lesson on art appreciation while the classroom teachers show slides in the schools. Television also is used for similar purposes. Art museums in the larger cities have taken the lead, because of their wealth of illustrative material and large, nearby television audiences, but a few metropolitan school systems also operate closed television circuits with the assistance of local cultural institutions, providing programs of drama and music as well as demonstrations of artistic techniques and talks on art appreciation. Occasionally programs are telecast from museum galleries.

Colleges and Universities.—Throughout the early 20th century there was much discussion of the place of the visual arts in higher liberal education. What should be their status, aims and methods? Classical education was disappearing rapidly, being replaced by a more practical, vocational emphasis and by a new emphasis on realistic, sociological study of contemporary civilization as a part of the liberal arts curriculum. Humanists deplored the loss of aesthetic, intellectual and other spiritual values in the new college curriculum; they called for a revival of such values, especially through increased attention to world literature, cultural history, the visual arts and the appreciation of music and theatre.

From 1918 onward orientation courses in humanities were established in an increasing number of colleges, especially for freshmen and sophomores. Some were historical in approach and some gave a cross section of the civilization of the present or of some other period. Nearly all incorporated some attempt at a survey of the visual arts, including an analysis of their materials, aims and principal current styles. College and university facilities for studio work in the practice of the arts were increased, and studio work sometimes was correlated with history. Every liberal arts college developed a collection of lantern slides, at first in black and white, later in full colour, and some began to collect educational films. Many college art instructors show comparatively little interest in educational psychology and methods, holding that these are unnecessary on the college level. But college art instruction often is too specialized and factual in approach, though in some colleges attempts have been made to integrate the practice of the arts with general studies.

Art Schools and Academies.—Independent art schools are under pressure to devote all the student's time to technical training, thus neglecting general education. Students in specialized art academies often are unwilling to study languages, literature, and other subjects desirable for general education, arguing that the pressure of competition in an art career requires intensive studio work and, moreover, that no one knows how much general education, aesthetic theory or art history is needed by a successful artist.

Art academies that are independent of either university or museum control tend to stress techniques, usually of a somewhat conservative type, though slowly following recent trends in art. Many teachers follow the trend toward radical distortion, abstraction and nonobjective form in painting, as is shown in annual exhibitions of work by students and teachers in the leading professional schools. The widespread disagreement about values in art causes many art teachers to be somewhat vague and timid in directing and criticizing students' work. They no longer feel confident of the rules they learned as students and have not found any definite substitutes. They show the student how to use various materials and techniques but say little about what he should do with them or what they believe makes a work of art good or bad. Many are uncertain about how much history of art they should know.

In teaching crafts, the art academies are somewhat more assured. They feel the need of definite instruction in materials and techniques, together with the use of simple machinery, as in weaving, ceramics and jewel cutting. The industrial arts, such as the design of household appliances, demand greater precision and clearly thought-out, functional planning than do the fine arts, in which the artist is freer to indulge his own subjective tastes and impulses. The spirit of self-confidence is strong in art students, and many of them feel little need to learn either from living teachers or from the works of old masters.

Art Museums.—Art museums and similar agencies, multiplying during the early 20th century, have provided an extensive sampling of the great styles of art. The rise of the art museum as an educational institution in the 20th century strengthened the international, cosmopolitan approach to world culture. The U.S. art museum, more than its European counterpart, brings together a selection from all arts and periods. A number of art museums have their own educational staffs, which work in collaboration with the art departments of schools, colleges and art academies in the vicinity. Such museum staffs, if sufficiently large, can specialize in presenting the same great works of art to persons of various ages, types and interests. Museum educational work has been diversified along many lines, including gallery guidance and organized courses on history and appreciation. It includes some studio work and drawing in the gallery, especially for children. During the week, it stresses co-operation with nearby schools and colleges, whereby museum visits are scheduled during the year at appropriate points in the school curriculum.

Teacher Training.—The training of prospective teachers of art has been making steady progress toward a synthesis of the necessary elements in the art teacher's education. A capable teacher of the arts needs much intellectual and pedagogical preparation, whereas an artist may get along with less. The teacher should have: (1) a fairly wide range of skills in the fine and applied arts; (2) knowledge of the history and theory of the visual arts; (3) some knowledge of the philosophy, psychology and classroom procedures of education; (4) a fairly wide general education, so that he can present the subject not in isolation but as an integral part of a liberal education. In short, he should be a well-educated person outside his field as well as in it. The difficulty lies in how to achieve this broad and diversified education together with excellence in a few artistic techniques, and to do so within the limits of a short course of study. (T. M.)

GREAT BRITAIN

Training of Artists.—The teaching of professional artists began in Britain in the 18th century with the organization of private academies by well-known artists. Free tuition for suitable candidates was given in the Royal Academy schools started in 1768, and full-time courses of instruction came into being in 1837 with the inauguration of the Government School of Design in

Somerset house. Its foundation was part of the new official policy in the recognition of "the need for extending a knowledge of the arts and the principles of design among the people" and to encourage "the direct application of the arts to industry."

With this same object, local art schools were started in 1842. By 1852 there were 17 of these and at the beginning of the new century about 200. In 1857 the Government school moved to be near to the newly opened South Kensington (later Victoria and Albert) museum; in 1897 it became the Royal College of Art.

These consistent attempts to enlarge the contribution of art to industry and among the people, however, were not successful. Industrialists gave them scant encouragement; local authorities, on whom the support of local art schools depended, were apathetic. The type of instruction given by the graduates of these schools was devoid of the lively quality that practical manufacturing experience gives. It was generally ineffectual in any creative sense, as teaching was repetitive, based on copying past styles of art.

In consequence of manufacturers' continual complaints that they could not find designers, few of whom found their way into industry, the Royal College schools of painting and sculpture were compounded with the Government School of Design at the turn of the century, in order to give fresh life to the application of design in industry. Despite the achievement of some renown by its departments of fine art, however, the school of design still continued its decline into mediocrity.

The school of English painting, which had made an inspiring contribution to European art in the 18th and early 19th centuries, tended to adopt a servile acquiescence to the primarily literary and sentimental bias and to the vulgar tendencies of its age. This attitude was more and more reflected in teachings, and the ordinary citizen found little or no room for the cultivation and exercise of his visual sensibility in the kind of academicism that pervaded all aspects of artistic activity.

Although the development of the great national collections of art and design produced distinguished scholars of art and a heightened understanding within a comparatively small circle of well-educated people, this influence did not extend far or deeply. The academic approach of the "expert," which dictated their sustained attempts to infuse art into the community from the top down, appeared in practice to set up at the same time a barrier between the comprehension of art and the ordinary citizen or to canalize his innate feeling into a merely passive "arty-crafty" sentimentalization of it. Art and design were at their lowest ebb by the end of the century, owing to the stubborn adherence to the fallacy that art was a one-way process.

20th Century.—Before the beginning of the new century the valiant struggles of a few individual groups of artists helped to free visual art from predominantly false standards, and new live conceptions, returning rather belatedly from the European continent, began to invade art teaching. In its last decade the Slade School of Art, as an independent school attached to the University of London, took a decisive lead in focusing these ideas and in relating its practice of drawing and painting and observation of first-hand experience to a close study of the content of great art. Under two famous professors, Fred Brown and Henry Tonks, the distinguished artists this school produced began to challenge the lifeless domination of official art. With others of the same mind they founded the New English Art club independently of the Royal academy and did much to reinstate a worthier school of British painting. At the same time they helped to bring a new focus into all levels of art teaching.

By the end of the first half of the century the indeterminate nature of professional art school courses in the Royal college and in local art schools had given way to a more closely coordinated structure, and the quality of teaching, with a greater percentage of experienced practising artists teaching part-time, had been improved. Art schools offer a four-year course, qualifying their pupils after examination for the national diploma of design. After another concentrated year's course those who matriculate, under the government scheme, may obtain a teacher's diploma, giving them degree status as teachers. Higher qualification is given by the Royal College of Art (associate) and the Slade school (London university diploma).

In 1936 Lord Hambledon's committee gave clear advice that the Royal college's preoccupation with the fine arts should yield to the overriding purpose of studying "applied art in all its forms with particular reference to Industry." Although this purpose was delayed by World War II, the college's scope thereafter was widened to provide a highly professional and imaginative standard of instruction in design, and through its influence with many other schools, as for example the London County council's historic School of Art and Craft, invaded and stimulated the world of industrial design. The Bray report of 1948 allowed each school to share in the assessment of its candidates' abilities; an advisory committee on art examination was set up in 1949. The admirable principle that art schools should be adapted to serve the particular needs of their own areas was established. It resulted in the formation of regional schemes in which schools comprehensively serve the needs of the area.

Professional teaching of artists based firmly on the experience of the past thus is adequately assured, but there still remains an almost complete void between this provision and the wider general need of the public for art and for the expression of its own vital experiences by this means. Further, despite the achievement by teachers in art schools in broadening their pupils' experience, their main work inevitably is concentrated on producing in the shortest time professionally competent and highly qualified artists, securing for them immediate financial security. This paramount duty scarcely enables the art schools to foster direct contact with the keener artistic observation and with the experience of life outside the school that is so valuable in the early formation of a creative artist. Art schools still tend to be isolated from the community rather than a part of it. They cannot be directly concerned with the creation of a living art in society which will surely interpret its common moods. Something also is required to ensure the return of art as a source of ideas, inspiring the life of the people and creating once more a dynamic expression of civilization.

Art Teaching in General Education.—Art teaching in general education, which has largely developed separately from that in professional schools of art, came to life in the second half of the 19th century with new experiments stimulated by the ferment of ideas emanating from John Ruskin and William Morris. A strong indigenous approach to the subject arose when a number of independent minds began to discover, empirically from experience, that children were capable of lively expression through drawing and painting and that this was not dependent on prior acquisition of a taught adult technique. The child had his own technique, found through practice.

The most significant contribution to these as yet vaguely understood facts was that of T. R. Ablett, who provided new methods for stimulating children's essential creative ability. He propounded the real aim of such activity in children as "drawing for delight," founding in 1888 the Royal Drawing society, which held its first exhibition of children's art in 1890. The results were generally acknowledged to be remarkable; the society's influence was great and has spread ever since.

At the turn of the century, at Birmingham, R. Catterson Smith's teaching was equally interesting. He fired his pupils' natural ability "through the cultivation of the power of mental imagery," fed by the continual drawing of remembered observation." His success re-established the importance of prior digestion by the artist of the details and fundamental form of observed facts before he is able to interpret them vividly as a summary in drawing.

More important still were the results of Smith's teaching as practised by his pupils Marian Richardson and Marian Duffield. Miss Richardson found and perfected new methods and mediums, as in her development of Ablett's "writing patterns," so that for the first time the child had suitable means, matching his own eloquent sense of design, colour and drawing, to express his emotional and imaginative conceptions. Through the work of her disciples, working in many schools, she showed how such expression could enhance the child's whole personality. She was influenced by the great Austrian pioneer, Franz Cizek, but Cizek confined his teaching to the few and gifted, while Miss Richardson

was able to show that eloquence in emotional expression among children was in fact a general gift, requiring only the opportunity and a relationship akin to love between teacher and child to bring it to fruition. Miss Richardson crystallized much individual experiment in teaching, giving a clear basis and point for the development of teaching method at all ages. Further, her work directly influenced the general attitude and practice of teachers in all aspects of the education of the younger child.

Acceptance of the conception that the creative instinct in the arts was also a very general one at the adolescent age, however, was very much more difficult to obtain. All long-standing educational tradition seemed against it. "Childish" intuition and emotional expression often were thought to be a hindrance to the clear development of an "adult" logical faculty, which at adolescence should be universally applied and which could prove adequate, it was thought, in all realms of human thinking. In the late 1920s and early 1930s a group of young teachers from the Slade school advanced the idea that much of the instability of youth and incompleteness of adult personality and character were due to this concentration on the development of only one side of the mind. This approach worked to the exclusion and consequent destruction in adolescence of the qualities of emotional inspiration, courage and individual discovery that are fundamental to this period of development and to the maturing of deeper spiritual and intellectual perceptions. The group at the Slade school believed that their experience in teaching children proved, in a practical realizable sense, that "there is not a special kind of person called an artist, but that each person is a special kind of artist." A paramount aim of education, therefore, should be to discover and develop the artist in every man. Only so would art again become a vital force, creating a language for the exchange of those social, spiritual and common ideas for which scientific analysis and the language of words proved inadequate or altogether impotent. Such self-discovery could also control the artist's developing emotional instincts and help the realization of a self-discipline on which the acquisition of a mature, balanced adult personality largely depended. With a few notable exceptions—such as Sir Michael Sadler and R. R. Tomlinson, whose books on child art have long been an influence in many countries—these ideas seemed unconvincing both to official art teaching and in general education.

This group of teachers started a society, the New Society of Art Teachers, to prove these truths; later, in amalgamation with the Art Teachers' guild it became the Society for Education Through Art. Before World War II it initiated a number of activities to establish these beliefs, such as that for the regular supply of examples and reproductions of art in schools, and a journal called *Athene*. Through exhibitions of school art, in its wide variety, they tried to find how a finer, not a less adult, technique was brought into being as an intrinsic part of live expression, not in separation from it; each language having its own unique kind of drawing, design and use of colour to interpret experience.

Although World War II delayed many projects, such as that for an institute of research into the nature of the growing faculty of intuitive imaginative expression, it produced one noteworthy result in the publication of the classical work on the subject by Sir Herbert Read, *Education Through Art* (1943). The findings of this book, relating the understanding of the discoveries made by art teachers to contemporary psychological discovery, established a reasoned unity to propositions arising out of these achievements which have been described as the most outstanding educational discovery of the 20th century.

After the war the Society for Education Through Art attempted to link painting in schools much more securely to contemporary art in its yearly "pictures for schools exhibitions," showing works of contemporary artists that could be bought by schools. Certain local education authorities, such as those of Leicester, Derby, London and South Wales, initiated notable schemes for providing schools with a regular flow of works of art. International co-operation was sought through UNESCO and supported by the ministry of education. As a result an international seminar was held in Bristol in 1951 with the subsequent formation of the International Society for Education Through Art (*see* below, *International Co-operation*). Co-operation among the different arts and between art and science teaching in education was initiated, leading to the formation of the Joint Council of Education Through Art. Similar expression among groups of adult nonprofessional artists showed the ability of many ordinary people to translate, through individual and quite separate ways, their own experience into painting. Work of great interest, in adjusting the problems of the mind, has been achieved through art both for those ill in mind and body and for educationally subnormal persons.

In 1957 the London County council in a very large exhibition held a review of the different ranges of visual art, growing through all its stages to maturity. The exhibition also demonstrated not only the result of one gifted pupil's work but many different achievements of the pupils in one class, each painting a given subject with his own particular interpretation of experience. In the growth of "comprehensive schools" and their regular teams of art instructors, the fuller realization of a live art pervading a whole school community and producing its own expression and decoration has been made possible. By the 1960s it was hoped that local centres would come into being, where teams of nonprofessional artists leaving schools could carry their expression and interpretation of contemporary experience into contemporary life. Increasingly it was being considered how an art of the people, inspired by the life of the community, could arise and, together with the art of the professional artist, reveal a greater art epitomizing the age and inspiring a richer conception of civilization in the future. Such an event, however, would seem to require a more objective view of the nature and function of art than that which still tended to confine much professional teaching.

(A. B.-Ru.)

EUROPE

The technical term "art education" is used, except in France and Spain, only with reference to academies of art and art schools that also include a section for the training of art teachers, and to pedagogic academies; in other educational establishments different terms can be found for the various activities connected with fine arts. In the curricula of primary and secondary schools the word "drawing" is used, alone or in connection with "handicrafts." In Switzerland (Bern) painting and modeling, in Spain studio work and needlework, are added instead of handicrafts. In the Federal Republic of Germany the subject is called "art and handicrafts" in primary schools, "fine arts" in secondary schools. Other official terms are "art lessons" in Greece and "art courses" in Hungary.

The number of hours assigned to the subject in secondary schools varies according to the type and character of the school, oscillating between 1 and 3 hours weekly, and exceptionally rising to 9 or 11 hours in secondary schools for girls in the Netherlands. Restrictions are common in the upper forms (grades). Many countries do not demand a definite arrangement of the lessons among the youngest age groups. Art education is part of the entire instruction. In any case—explicitly mentioned or not—it is compulsory in the primary schools, with a very few exceptions for the upper forms. This compulsion is based on the knowledge that children are able to express themselves better through art than through words and that art thus fosters their mental growth. In most secondary schools on the European continent art education is compulsory during the first four forms, becomes an optional subject in the upper forms and very often disappears from the curriculum of the last form.

All continental countries acknowledge the educational value of art education and agree that it fosters self-possession, concentration, attentiveness, discipline, self-reliance and responsibility. Most of the continental curricula, without any difference in the primary and secondary levels, emphasize the training of observation, imagination and aesthetic feeling. The abilities achieved through art education are sometimes deemed an important help in the mastering of other subjects. Some countries are more interested in the acquisition of techniques in art education, yet they stress that techniques are not to be an end but a means to an end.

It is known, of course, that art education contributes, as does

no other subject, to an understanding of the child's psychological disposition and thus gives the teacher necessary insight. However, continental European countries refuse to let the children work only to serve psychological interpretation, as this would result in the loss of educational purpose. In special schools art education is used for observation and development of retarded children. Besides general aims, particular goals are: training of manual ability, memory and intellect, and development of critical analysis, power of judgment, sense of quality, interest in works of art and awareness of their backgrounds.

Drawing appears first among the activities of art education. Painting gradually develops from it to form a special branch. Drawings develop from the observation of nature and out of imagination and memory. Besides these, graphic techniques and the so-called intermediary graphic procedures are practised, together with calligraphy and illuminated writing. Handicrafts such as bookbinding, wood carving and metal and leather manufacturing are added. Puppets are made everywhere.

Art appreciation generally is assigned to the secondary level. It is very often built up on a historical basis or on criticism of styles. Boys and girls get instruction equally, but adaptations for their tastes are made, being specially worked out for different mental abilities. The aim of art education ultimately is understanding of the nature of creative process and apprehension of the values of life as realized through works of art. The awakening and development of creativity, which should help the child to understand his own personality and to discover his own way of expression, is achieved by a program that examines the various possible ways of creating form. Contemplation of a work of art fosters creative work as well as understanding of the art object itself; at the same time it helps to develop the faculty of independent judgment.

The many kinds of materials and tools that are of importance in art education are sometimes provided free of charge to children of primary-school age. Materials used for art appreciation, such as reproductions and art books, are owned by the schools; slides and films are lent out by official centres. The study of original works of art is favoured, and visits to exhibitions and art galleries, in addition to exhibitions of the work of outstanding artists in the schools, contribute to the art program.

In all continental primary schools art education is given by the form master, who first receives teacher training at secondary schools, pedagogic academies and teachers' training schools. In some countries artistic activity is emphasized in such schools. Teachers specialized in art teach the subject in the upper forms of the primary level, most of these having attended official or nonofficial art courses. All teachers are given the opportunity to broaden their learning in continuation classes arranged by educational authorities or art teachers' associations. It is taken for granted that the secondary-school art teacher is an artist, because only as an artist can he possess the sensibility, vitality and strength necessary for his task. Secondary art teachers are trained at academies of fine arts or applied arts, in art schools or in special art centres as in Poland and Rumania; training lasts between two and five years and stress is often laid on the artistic side rather than on the pedagogic. Secondary-school art teachers, except in Italy and Switzerland, hold the same position as teachers of other subjects, but in most countries art teachers give more lessons than other teachers do. They are advised by art inspectors. In France and Norway art teachers are able to consult the museum staffs. Art teachers' associations exist in most European countries. Their members are mainly teachers of the secondary schools but also include primary school teachers, very rarely teachers of academies.

Nearly all countries publish technical journals and organize meetings and congresses. Adult colleges have the same aim in art education as primary and secondary schools, without the possibility of achieving the same successes. Their courses are directed by art teachers, artists and handicraftsmen. In the Federal Republic of Germany, Sweden and France the handicraft art schools are of special significance.

Art education for young people attending vocational schools is not yet fully exploited or its value realized. In a review of the situation on the continent of Europe it must be said that, in spite of the progress mentioned above, the estimation of art education has shown retrogression during the 20th century. (R. Cu.)

INTERNATIONAL CO-OPERATION

At the close of World War II, internationally minded art teachers in many countries looked forward to a period of active co-operation through the newly established United Nations Educational, Scientific and Cultural organization (UNESCO). At UNESCO headquarters in Paris, special sections of the staff were formed to facilitate co-operation in the visual arts, art education and museum work. Arrangements were made to work with professional societies in several member countries in the visual arts, drama, dance and music. In 1947 and 1949 international committees of experts met under the chairmanship of Thomas Munro (U.S.) and Sir Herbert Read (Great Britain) to plan a program for developing the arts in general education. UNESCO was to act as a world clearinghouse for the exchange of information, exhibitions, plans for international art festivals, and professional conferences. Supporting panels of artists and teachers met in Paris, London, Washington and New York. Under the leadership of Trevor Thomas (Great Britain), then a member of the UNESCO staff, a magazine on art education was published in English and French. With C. D. Gaitskell (Canada) as director an international seminar on the visual arts in general education was held in Bristol, Eng., in 1951, followed by one in Tokyo.

Some important further steps were taken: (1) As a sequel to the Bristol seminar, a volume entitled *Education and Art* was edited by Edwin Ziegfeld (Paris, 1953) with articles by 45 art educators from North and South America, Europe, the near and far east, and with many illustrations in colour of children's art work. (2) The International Society for Education Through Art (INSEA) was organized, with headquarters in Paris; Edwin Ziegfeld (U.S.) was its first president. (3) An assembly of the society, devoted to "Art Education and Adolescence," was held at The Hague in Aug. 1957. (4) Technical advisers on arts and crafts were sent to Afghanistan and other countries requesting them. (5) A series of large books of colour reproductions of paintings from Egypt, India, Italy and elsewhere was issued under the direction of Peter Bellew of the art section of UNESCO, together with catalogues of colour reproductions available for purchase elsewhere. (6) Through the museums section, steps were taken to aid in the preservation and restoration of great monuments of art throughout the world.

Through other agencies, especially the U.S. state department and various private foundations, many artists, art students, teachers and museum workers from the United States and foreign countries have been given travel grants for study abroad. Although not all countries of the world participate, the ideal of cultural interchange in the arts and in methods of creative education is gaining wide support.

ARTEMIDORUS. (1) A geographer of the ancient Greek city of Ephesus who, in about 100 B.C., compiled a systematic geography in 11 books, using both his own itineraries in the

Mediterranean and the records of others. His work is known only from references in Strabo, who made much use of it, from fragments preserved by later authors and from the surviving part of an abridgement, attributed to Marcianus of Heraclea (possibly early 5th century), of his periplus (coastal guide) of the Mediterranean and Euxine. (2) A soothsayer of Ephesus who flourished during the 2nd century A.D. His *Oneirocritica*, or interpretation of dreams, in four books, is extant and affords a valuable insight into ancient superstitions. It is mainly a compilation from the works of earlier authors. Artemidorus was called A. Daldianus, either after his mother's home, Daldis in Lydia, or because he was an initiate of Apollo Daldiaios. (Wm. C. B.)

ARTEMIS, the Greek goddess of wild animals and vegetation, of chastity, childbirth and the hunt, identified by the Romans with Diana (*q.v.*), was the most popular of all goddesses with the ordinary worshiper. Her character and function vary greatly from place to place; the many-breasted Artemis of Ephesus and the Artemis *Lochia*, who aided women in labour, contrast strangely with the virginal huntress familiar from Euripides' *Hippolytus*. Yet apparently behind all forms lies the goddess of wild nature, who dances, usually accompanied by nymphs, in mountains, forests and marshes.

Artemis' worship probably flourished in Crete or on the Greek mainland before the Hellenic immigration during the 2nd millennium B.C. The Minoan Cretan pantheon included a Mistress of Animals who supervised wild nature and the hunt, and who was closely related to the goddess of the tree cult. The Mistress of Animals likewise appears on artifacts of the Mycenaean Greek culture of the later 2nd millennium, and their form closely resembles 7th-century Greek representations of Artemis. The name Artemis defies successful derivation from Greek or any Indo-European tongue and may well be of Minoan origin. Scholars have claimed that her name appears on a Mycenaean tablet, and though the decipherment of Mycenaean Greek is still uncertain, continuity of functions and artistic type render Artemis' transmission through the Mycenaeans from Minoan beginnings reasonably certain.

Many of Artemis' local cults preserve traces of other deities, often with Greek names, suggesting that, upon adopting her, the Greeks identified Artemis with nature divinities of their own. Even where such syncretism is not discernible, non-Minoan influences may be seen: phallic dances and symbols, of which the Minoan religion shows little or no trace; the sibling relationship between Artemis and Apollo (*q.v.*; he immigrated from Asia Minor after the early Hellenic settlement of Greece) and the consequent belief that she too was the daughter of Zeus and Leto; and her occasional encroachments upon Apollo's domain, such as her assistance in healing Aeneas in the *Iliad*.

The Mycenaean princes encountered wild nature rarely except while hunting, so that to Homer, who so often reflects their values, Artemis is essentially the huntress; Hera contemptuously confines her to this role in book 21 of the *Iliad*. From it stem her epithets "arrow-shedder" and "noisy" (probably referring to the din of the boar hunt). Embodying as she does the sportsman's ideal, besides killing game she protects it, especially the young; such is the Homeric significance of the title "mistress of animals." Because she is the bow-carrying goddess, it is she who sends sudden death to women (once to a man, Orion the hunter, in the *Odyssey*) through the "gentle darts" whose effect is specifically contrasted with death by long illness in book 11 of the *Odyssey*. Her archer brother Apollo is responsible for the sudden deaths, off the battlefield, of men; he slays the sons, she the daughters of Niobe (*q.v.*). Somewhat surprisingly, Artemis appears alongside Aphrodite in the *Odyssey* as the paradigm of female beauty; her stature especially is praised.

Since Artemis belongs to the rural populace rather than the urban court, Homer understandably displays little interest in her. Later poets, too, tended to favour other Olympians, perhaps because they had difficulty establishing for Artemis an extensive cosmological role. Chastity, the hunt, and the out-of-doors are not spheres of human concern comparable in importance to love, war, or moral and intellectual excellence; and even virginity is often regarded as the denial of Aphrodite rather than the affirmation of Artemis. Details such as Artemis' connection with the dance and the nymphs were drawn not from poetic imagination but from cult.

Dances of maidens representing nymphs are especially common in Artemis' worship as goddess of the tree cult, a role probably deriving from Minoan religion and especially popular in the Peloponnesus. At Caryae, for instance, dances of maidens symbolizing dryads (the usual term for tree nymphs) honoured Artemis *Caryatis*; they and the nut-tree nymph, Carya, were once changed into trees. Elsewhere are Artemis *Cedreatis* (goddess of the cedar) and Artemis *Apanchomene* ("hanging"), whose image was presumably suspended from a tree and who may have developed from the dying vegetation-goddess of the Minoans.

THE MANSELL COLLECTION

THE ARTEMIS OF GABII. IN THE LOUVRE, PARIS

The tree cult is one form of the worship of Artemis as goddess of wild vegetation. Throughout the Peloponnesus, bearing such epithets as *Limnaea* and *Limnatis* ("lady of the lake"), she supervised waters and lush wild growth, attended by nymphs of wells and springs (ordinarily called naiads). In parts of the peninsula her dances were wild, lascivious and often phallic, accompanied by timpani and reed flutes. To such musical origins was bucolic poetry anciently traced; Caryae vied with shrines in Dorian Sicily for the honour of having been its birthplace. In a sanctuary east of Sparta, Artemis bore the unexplained epithet *Orthia*, perhaps once an independent divine name. Her worshipers there included masked dancers, and there exists a lyric by Alcman which rival choruses of maidens probably sang in her honour one morning before dawn. If, as the ancient commentary suggests, these girls dedicated a plow to the goddess, it is one of the few indications that Artemis extended her activities to cultivated vegetation. Plant life of some kind she certainly supervised there: she was called *Lugodesma* ("withybound," referring in part to the condition of her statue), and sickles were offered her. Later the cult became famous for a mysterious ritual, the scourging of youths at her altar.

Outside the Peloponnesus, Artemis' most familiar form is the mistress of animals. Poets and artists usually pictured her with the stag or hunting dog, but the cults show considerable variety. In Phocis and elsewhere, Artemis *Laphria* (meaning unknown) received the sacrifice of a large number of living animals of all sorts, heaped upon a funeral pyre and burned. Artemis *Agrotera* ("of the wild") received every year from the Athenians 500 goats as a thank-offering for her help at Marathon. At Brauron in Attica, maidens called "bears" dressed in tawny cloaks and danced for Artemis; the bear may also be a theriomorph of Artemis *Calliste* ("fairest") in Arcadia. The Tauropolia festival at Halae Araphenides, also in Attica, honoured Artemis *Tauropolos* ("bull-goddess"), who received a few drops of blood drawn by sword from a man's neck. It may have been partly this obvious surrogate for human sacrifice which led Euripides (in *Iphigenia in Tauris*) to derive the cult (together with the Brauronian) from the Crimean Taurians, among whom Iphigenia, in one version of the legend, immolated strangers to Artemis. Iphigenia herself was nearly sacrificed to Artemis by her father, Agamemnon; the goddess rescued her, substituting a bear or stag, a change of sacrificial object which must very nearly reflect historical truth. In most versions of the myth Iphigenia is actually killed, an act which the poets ex-

plain variously; according to Aeschylus (in *Agamemnon*), Artemis is angrily determined to make the leader of the Trojan expedition pay dearly for honouring the code of blood revenge for the rape of Helen. All these cases of human sacrifice honoured the mistress of animals and are likely to be early, though not necessarily Minoan. In a few cults, especially where the deer-festival Elaphebolia was celebrated, Artemis was worshiped as a huntress, but such rites are relatively rare, the concept belonging mainly to aristocratic private cult and to poetry and sculpture.

Many scholars have held that Artemis was originally a mother-goddess, descended from a Cretan Mother of the Mountains similar to the Asian Magna Mater (*see* GREAT MOTHER OF THE GODS). A familiar artistic type of the Minoan Mistress of Animals, showing the goddess standing on a heap of stones (mountain?), in a flounced skirt with rod (spear?) in hand and flanked by lions, is highly reminiscent of the Magna Mater and certainly shows eastern influence. But derived artistic types do not necessarily impose the religious interpretations of their originals; motherhood is not an obvious feature of the design, and the Minoan language cannot be read. Attempts to discover in the later Greek mistress of animals (Artemis herself) traces of a mountain-mother have not been conspicuously successful. Mountain shrines, whose neighbourhood she wandered, presumably accompanied by orestiads (mountain nymphs, also called oreads), were indeed hers; perhaps here she carried the torches which she bears on vase paintings and which have hopefully but unconvincingly been called marriage torches. The many-breasted Ephesian Artemis, whose temple was one of the seven wonders of the world, was a mother, in fact a form of the Magna Mater. But she was distinctly different from Artemis in Greece; the Greeks doubtless made the identification because both were mistresses of animals, but there the resemblance ceases. Goddess of childbirth Artemis was, often identified with Eileithyia; on occasion she was offered the clothes of women who died in childbirth. She was sometimes called *Kourotrophos* ("nurse"). But midwife and nurse are not mother, and lovemaking and probably conception, too, are Aphrodite's concern. The chorus in *Oedipus Rex,* for instance, invokes Artemis on behalf of the Theban women, who are not barren, but are unable to "surmount their shrieking pangs by births." In later times she was identified with Hecate (*q.v.*) and with the moon, whose monthly cycle was early connected with woman's, but efforts to see Artemis as a moon-goddess in early cult are unconvincing. Premarital ceremonies were occasionally held in her honour, especially in Locris and Boeotia in the cult of Artemis *Eucleia* ("renown"; Eucleia was probably once an independent divinity), but they do not seem to have aimed at fecundity. Only very indirectly, where Artemis was the goddess of woman's life in general, did motherhood become her sphere.

The frequent stories of the love affairs of Artemis' nymphs are supposed by some to have originally been told of the goddess herself, presumably as mother-goddess. Thus Callisto ("Fairest"), who bore Arcas, progenitor of the Arcadians, to Zeus, is supposed to be Artemis; she may indeed be related to Artemis *Calliste,* but it cannot be said whether her seduction was invented while she was identified with Artemis (if she was) or later. Often the nymph escaped her amorous pursuer; Britomartis, who was once a Cretan goddess and probably related to Artemis, remained chaste. It is unreasonable to identify Artemis only with those nymphs who succumbed.

The poets after Homer stress Artemis' chastity: Homeric hymn 5 attributes her immunity to Aphrodite to her delight in the hunt, dancing and music, shadowy groves and the cities of just men. The reference to city life is unusual; sole jurisdiction over 30 towns, promised her by Zeus (Callimachus, *Hymn to Artemis*), was apparently never her portion; few writers mention the role, though market-place temples occasionally are mentioned. But that the goddess of the unconquered wilderness should be free of sexual desire, a taming and subduing force, seems altogether natural. This thought paved the way for the archetype of the virgin huntress, whose possibilities as a symbol of human aspiration were fully exploited by Euripides in the *Hippolytus* (*q.v.*). Its hero in consecrating himself to Artemis rejects not only Aphrodite but mankind itself, which is subject to Aphrodite; Artemis' wild haunts represent an ultimately impossible escape from the human condition.

The wrath of Artemis is proverbial, for to it myth attributed wild nature's hostility to man. In sending the Calydonian boar against Oeneus, Artemis demonstrates the costliness of his failure to remember nature's power (*see* MELEAGER; ATALANTA). The hunter above all cannot afford such forgetfulness; Actaeon (*q.v.*), for carelessly surprising the naked Artemis, is changed from hunter to hunted, to a stag who is devoured by his own hounds. Yet Greek sculpture avoided Artemis' unpitying anger as a motif; the goddess herself did not in fact become popular as a subject in the great sculptural schools until the relatively gentle 4th-century spirit prevailed. The rather scant remains reflect such thoughtful pride as may be found on the Vienna statuette or the girlish charm of the Gabii huntress, both perhaps spiritual children of Praxiteles' lost work.

(W. M. SE.)

ARTEMISIA, daughter of Lygdamis, was queen of Halicarnassus and Cos about 480 B.C. She took part in the expedition of Xerxes against the Greeks, and fitted out five ships, with which she distinguished herself in the sea fight near Salamis (480). According to Herodotus it was her advice which decided Xerxes not to risk another battle, but to retire at once from Greece.

ARTEMISIA, the sister and wife of Mausolus (or Maussollus), king of Caria, was sole ruler *c.* 353–350 B.C. She built for her husband, in Halicarnassus, the magnificent mausoleum, which was one of the seven wonders of the world. Artemisia was also known as a botanist and medical researcher. She discovered and named several herbs; *Artemisia* is named after her.

See HALICARNASSUS.

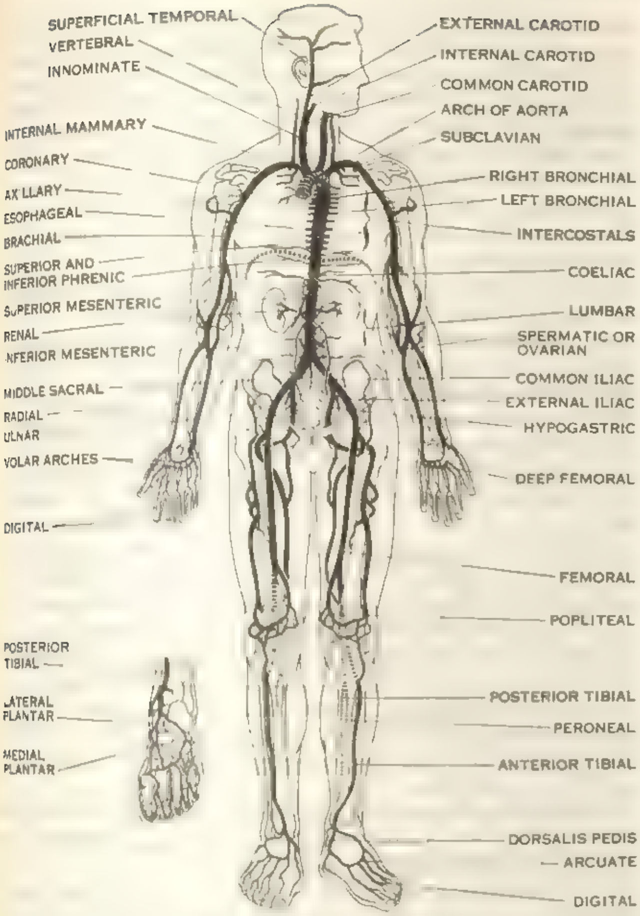
See Pliny, *Natural History,* vol. xxv, p. 73, vol. xxxvi, pp. 30 *et seq.*

ARTEMISIA, a large genus of aromatic, bitter-juiced herbs or shrubs of the family Compositae, comprising about 100 species, most abundant in arid regions, notably in the western United States, the Asiatic steppes, South Africa and South America. They often have much divided leaves and inconspicuous flowers borne in very numerous small heads. Several are grown for ornamental and medicinal purposes. Four species are found in Great Britain; 40 or more occur in the United States and Canada, chiefly from the Great Plains westward, and several old world species have become widely naturalized, such as the southernwood (*A. abrotanum*), the wormwood (*A. absinthium*) and tarragon (*A. dracunculus*). The beach wormwood and mugwort (*qq.v.*) are less aromatic, and are weedy escapes from cultivation in eastern North America. The well-known sagebrush (*q.v.*) of western North America is a silvery shrub, four to six feet high (occasionally more), and covers many thousands of square miles.

The dried flower heads of several Asiatic species are used for the extraction of santonin, a drug used to expel roundworms from the gastrointestinal tract. Two of the chief sources of santonin are *A. cina* of Iran and Turkistan and *A. maritima,* found from England to Mongolia. Closely related, the products of either are commercially known as Levant wormseed. Both are woody perennials or subshrubs, bearing numerous tiny yellowish flower heads, usually gathered in July. (N. TR.)

ARTEMOVSK (formerly BAKHMUT), a town of Donetsk *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., lies on the Bakhmut river, a tributary of the Donets, about 40 mi. N.N.E. of Donetsk. Pop. (1959) 60,626. It is connected by railway to the coal-mining town of Gorlovka and to Kharkov. The largest salt mines in the U.S.S.R., worked since the 17th century, are at Artemovsk. There are also alabaster and glass works, food and light industries. Near the town is the Mironovskaya electric plant. (R. A. F.)

ARTERIES, in anatomy, are the muscular and elastic tubes that carry the blood away from the heart to the tissues. Since after death, the arteries are always found empty, the older anatomists believed that they contained air, and to this belief they



FROM MILLARD, KING AND SHOWERS, "HUMAN ANATOMY AND PHYSIOLOGY," 4TH ED., SAUNDERS (1956)

FIG. 1.—DIAGRAM OF THE ARTERIAL SYSTEM

owe the name, which was originally given to the windpipe. Two great trunks, the aorta and pulmonary artery, leave the heart and divide again and again until they become minute vessels to which the name arterioles is given.

The larger trunks are fairly constant in position and receive definite names, but there is an increasing inconstancy in the position of the smaller branches. Many arteries are tortuous, especially when they supply movable parts such as the face or scalp, but when one or two sharp bends are found they are generally due to the artery's going out of its way to give off a constant and important branch.

Small arteries unite (*i.e.*, anastomose) with others near them very freely, so that when even a large artery is obliterated a collateral circulation is carried on by the rapid increase in size of the communications between the branches coming off above and below the point of obstruction. Some branches, however, such as those going to the basal ganglia of the brain and to the kidney, are known as end arteries, and these do not anastomose with their neighbours at all; thus, if one is blocked, arterial blood fails to reach the area normally supplied. As a rule, there is little arterial anastomosis across the middle line of the body near the surface, although the scalp, lips and thyroid gland are exceptions.

The following account refers to the vessels as they occur in man.

Aorta.—The aorta lies in the cavities of the chest and abdomen and arises from the base of the left ventricle of the heart. It ascends forward, upward and to the right as far as the level of the second right costal cartilage, then runs backward and to the left to reach the left side of the body of the fourth thoracic vertebra, and then descends almost vertically. It thus forms the aortic arch, which has attached to its concave surface a fibrous cord, the ligamentum arteriosum, which connects it with the left branch of the pulmonary artery. The aorta continues downward close to the bodies of the thoracic vertebrae, then passes through an opening in the diaphragm (*q.v.*), enters the abdomen and descends in front of the bodies of the lumbar vertebrae as low as the fourth, where it usually divides into two terminal branches, the common iliac arteries. Above and behind the angle of bifurcation, however, a long slender artery, called the middle sacral, is prolonged downward in front of the sacrum to the end of the coccyx. It is really the terminal aorta, shifted in position.

Carotid System.—The branches for the head, neck and upper limbs arise as three large arteries from the arch of the aorta; they are named innominate (or brachiocephalic), left common carotid and left subclavian. The innominate artery is the largest and passes upward and to the right to the root of the neck, where it divides into the right common carotid and the right subclavian. The carotid arteries supply the two sides of the head and neck; the subclavian arteries supply the two upper extremities. Each common carotid artery runs up the neck by the side of the windpipe, and on a level with the upper border of the thyroid cartilage divides into an internal and external carotid artery.

Each internal carotid artery ascends through the carotid canal in the temporal bone into the cranial cavity. It gives off an ophthalmic branch to the eyeball and other contents of the orbit, and then divides into the anterior and middle cerebral arteries. The middle cerebral artery extends outward into the lateral (Sylvian) fissure of the brain, and supplies the insula (of Reil), the orbital part and the outer face of the frontal lobe, the parietal lobe and the temporal lobe; it also gives a chorioid branch to the chorioid plexus of the anterior medullary velum. The anterior cerebral artery supplies the inner face of the hemisphere from the anterior end of the frontal lobe as far back as the internal parieto-occipital fissure.

At the base of the brain not only do the two internal carotids anastomose with each other through the anterior communicating artery, which passes between their anterior cerebral branches, but also the internal carotid on each side anastomoses with the posterior cerebral branch of the basilar, by a posterior communicating artery. In this manner a vascular circle, the arterial circle (of Willis), is formed, which permits freedom of circulation between the arteries on opposite sides of the mesial plane. The vertebral and internal carotid arteries, which are the arteries of primary supply for the brain, are distinguished by lying at some depth from the surface in their course to the organ, by having curves or twists in their course and by the absence of large collateral branches.

The external carotid artery ascends through the upper part of the side of the neck, and behind the lower jaw into the parotid gland, where it divides into various branches. The external carotid artery gives off the following branches: (1) superior thyroid to the larynx and thyroid gland; (2) lingual to the tongue and sublingual gland; (3) facial to the face, palate, tonsil and submaxillary gland; (4) occipital to the sternomastoid muscle and back of the scalp; (5) posterior auricular to the back of the ear and the adjacent part of the scalp; (6) superficial temporal to the scalp in front of the ear, and by its transverse facial branch to the back part of the face; (7) maxillary, giving muscular branches to the muscles of mastication, meningeal to the dura

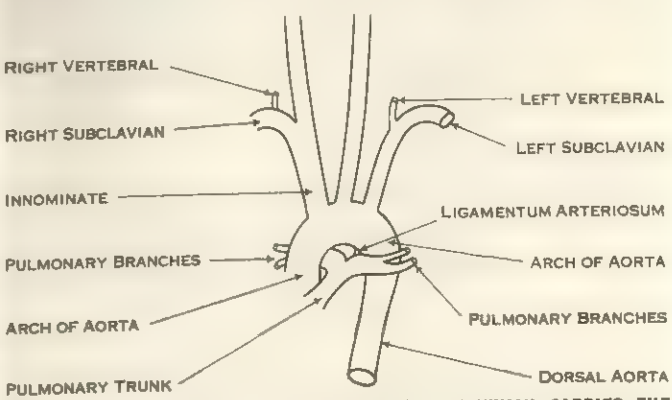


FIG. 2.—THE HUMAN AORTA, THE GREAT ARTERY WHICH CARRIES THE BLOOD FROM THE HEART TO ALL PARTS OF THE BODY EXCEPT THE LUNGS, AND ITS MAIN BRANCHES

mater, dental to the teeth and other branches to the nose, palate and tympanum; (8) ascending pharyngeal, which supplies the pharynx, palate, tonsils and dura mater.

Subclavian System.—The subclavian artery is the commencement of the great arterial trunk for the upper limb. It passes across the root of the neck and behind the clavicle, where it enters the armpit, and becomes the axillary artery; by that name it extends as far as the posterior fold of the armpit, where it enters the upper arm, takes the name of brachial and courses as far as the bend of the elbow; there it bifurcates into the radial and ulnar arteries. From the subclavian part of the trunk the following branches arise: (1) Vertebral, which enters the foramen at the root of the transverse process of the sixth cervical vertebra, ascends through the corresponding foramina in the vertebrae above, lies in a groove on the arch of the atlas and enters the skull through the foramen magnum, where it joins its fellow to form the basilar artery; it gives off numerous branches in its course. The basilar artery extends from the lower to the upper border of the pons Varolii; it gives off pontine, labyrinthine and inferior cerebellar branches and breaks up into four terminal branches, viz., two superior cerebellar and two posterior cerebral. (2) Thyrocervical trunk, which immediately divides into the inferior thyroid, the suprascapular and the transverse cervical branches. (3) Internal thoracic (or internal mammary), which supplies the anterior surface of the walls of the chest and abdomen and the upper surface of the diaphragm. (4) Costocervical trunk, which supplies the first intercostal space, and by its deep cervical branch the deep muscles of the back of the neck.

The axillary artery supplies thoracic branches to the wall of the chest, the pectoral muscles and the fat and glands of the armpit; a thoracoacromial to the parts about the acromion; anterior and posterior circumflex branches to the shoulder joint and deltoid muscle; a subscapular branch to the muscles of the posterior fold of the armpit.

The brachial artery supplies muscular branches to the muscles of the upper arm; a nutrient branch to the humerus; profunda or deep branches and ulnar collaterals to the muscles of the upper arm and the region of the elbow joint.

The ulnar artery extends down the ulnar side of the front of the forearm to the palm of the hand, where it curves outward toward the thumb and anastomoses with the superficial palmar or other branch of the radial artery to form the superficial palmar arch. In the forearm the ulnar gives off the interosseous arteries, which supply the muscles of the forearm and give nutrient branches to the bones; two recurrent branches to the region of the elbow; and carpal branches to the wrist joint. In the hand it gives a deep branch to the deep muscles of the hand, and from the superficial arch arise digital branches to the sides of the little, ring and middle fingers and the ulnar border of the index finger.

The radial artery extends down the radial side of the front of the forearm, turns around the outer side of the wrist to the back of the hand, passes between the first and second metacarpal bones to the palm, where it joins the deep branch of the ulnar, and forms the deep palmar arch. In the forearm it gives off a recurrent branch to the elbow joint; carpal branches to the wrist joint; and muscular branches, one of which, named superficial palmar, supplies the muscle of the thumb and joins the ulnar artery. In the hand it gives off a branch to the thumb and one to the radial side of the index, metacarpal branches to the interosseous muscles, perforating branches to the back of the hand and recurrent branches to the wrist.

Visceral Branches.—The branches of the aorta that supply the viscera of the thorax are the coronary, the esophageal, the bronchial and the pericardiac. The coronary arteries, two in number, are the first branches of the aorta, and arise opposite the anterior and left posterior semilunar valves, from the wall of the aorta, where it dilates into the aortic sinuses (of Valsalva). They supply the tissue of the heart.

The esophageal, bronchial and pericardiac branches are sufficiently described by their names.

The branches of the aorta that supply the viscera of the abdomen arise either singly or in pairs. The single arteries are the coeliac trunk, the superior mesenteric and the inferior mesenteric, which arise from the front of the aorta; the pairs are the suprarenal, the two renal and the two testicular or ovarian, which arise from its sides. The single arteries supply viscera that are either completely or almost completely invested by the peritoneum (see COELOM AND SEROUS MEMBRANES), and the veins corresponding to them are the roots of the vena portae.

The pairs of arteries supply viscera developed behind the peritoneum, and the veins corresponding to them are rootlets of the inferior vena cava.

The coeliac trunk is a thick, short artery that almost immediately divides into the gastric, hepatic and splenic branches.

The superior mesenteric artery gives off an inferior pancreaticoduodenal branch to the pancreas and duodenum; about 12 intestinal branches to the small intestine, which form in the substance of the mesentery a series of arches before they end in the wall of the intestines; an ileocolic branch to the end of the ileum, the caecum and beginning of the colon; a right colic branch to the ascending colon; and a middle colic branch to the transverse colon.

The inferior mesenteric gives off a left colic branch to the descending colon, a sigmoid branch to the iliac and pelvic colon, and ends in the superior rectal artery, which supplies the rectum.

The suprarenal arteries, small in size, run outward from the aorta to end in the suprarenal capsules. The renal arteries pass one to each kidney. Additional renal arteries are fairly common.

The testicular arteries are two long slender arteries that descend, one in each spermatic cord, into the scrotum to supply the testicle. The corresponding ovarian arteries in the female do not leave the abdomen.

Parietal Branches.—The branches of the aorta that supply the walls of the chest, abdomen and pelvis are the intercostal, the lumbar, the phrenic and the middle sacral.

The intercostal arteries arise from the back of the thoracic aorta, and are usually nine pairs. They run around the sides of the vertebral bodies as far as the commencement of the intercostal spaces, where each divides into a dorsal and a ventral intercostal branch. The dorsal branch passes to the back of the thorax to supply the deep muscles of the spine; the ventral branch runs outward in the intercostal space to supply its muscles, and the lower pairs of intercostals also give branches to the diaphragm and wall of the abdomen. Below the last rib a subcostal artery runs, with similar relations.

The lumbar arteries arise from the back of the abdominal aorta, and are usually four pairs. They run around the sides of the lumbar vertebrae, and divide into a dorsal branch which supplies the deep muscles of the back of the loins and an abdominal branch which runs outward to supply the wall of the abdomen. The distribution of the lumbar and intercostal arteries exhibits a transversely segmented arrangement of the vascular system, like the transversely segmented arrangement of the bones, muscles and nerves met with in these localities, but more especially in the thoracic region. Anastomoses of their ventral tips produce the internal thoracic (or internal mammary) arteries.

The two phrenic arteries supply the undersurface of the diaphragm.

The middle sacral artery, as it runs down the front of the

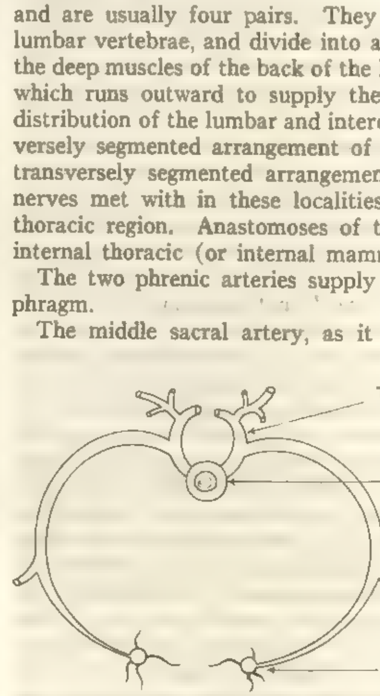

FIG. 3.—A PAIR OF INTERCOSTAL ARTERIES AND THEIR BRANCHES

sacrum, gives branches to the back of the pelvic wall.

The arteries to the pelvis and legs begin at the level where the aorta bifurcates into the two common iliacs.

Iliac System.—The common iliac artery, after a short course, divides into the internal and external iliac arteries. The internal iliac enters the pelvis and divides into branches for the supply of the pelvic walls and viscera, including the organs of generation, and for the great muscles of the buttock. The external iliac descends behind the inguinal ligament into the thigh, where it takes the name of femoral artery. The femoral descends along the front and inner surface of the thigh, gives off a profunda branch, which, by its circumflex and perforating branches, supplies the numerous muscles of the thigh; most of these extend to the back of the limb to carry blood to the muscles situated there. The femoral artery then runs to the back of the limb in the ham, where it is called the popliteal artery. The popliteal divides into two branches, of which one, called anterior tibial, passes between the bones to the front of the leg and then downward to the upper surface of the foot; the other, posterior tibial, continues down the back of the leg to the sole of the foot and divides into the medial and lateral plantar arteries; branches proceed from the lateral plantar artery to the sides of the toes, and constitute the digital arteries. From the large arterial trunks in the leg many branches proceed, to carry blood to the different structures in the limb. (F. G. P.; L. B. Ay.)

Pulmonary Trunk.—This stem is a short vessel that arises from the right ventricle and, extending upward and backward, passes first in front of the ascending aorta and then to its left. Reaching the concavity of the aortic arch, it divides into right and left pulmonary arteries.

The longer and larger right pulmonary artery runs horizontally to the root of the right lung, and there divides into two branches; the larger one supplies the middle and lower lobes of the right lung; the smaller enters the upper lobe. The left pulmonary artery also runs horizontally and, at the root of the left lung, sends a branch to each lobe. Unlike all other adult arteries, these vessels carry impure blood.

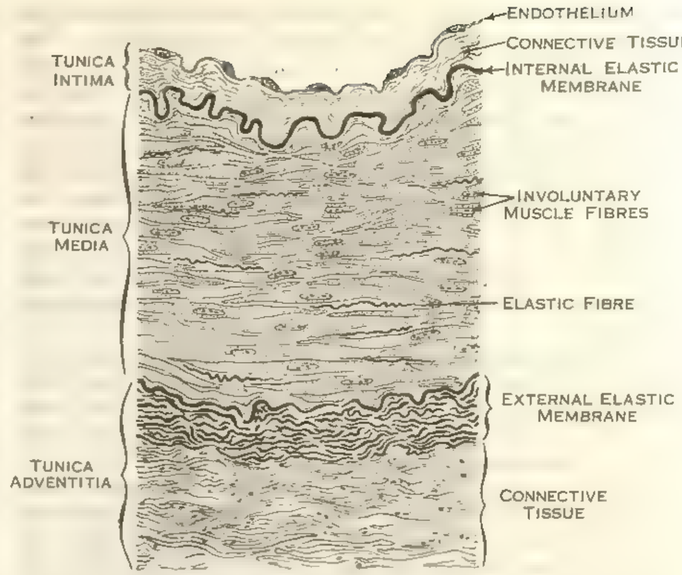
Structure of Arteries.—The wall of a typical artery consists of three coats. The outermost is the tunica adventitia, composed of fibrous tissue; its inner layers commonly form a zone of elastic fibres, the so-called external elastic membrane. The middle coat, the tunica media, is the thickest of the three. It contains unstriped (involuntary) muscle fibres, arranged in a circular manner, and a varying amount of elastic tissue (lacking in arterioles; largely replacing the muscle in the aorta and its largest main branches). The innermost coat is the tunica intima. Passing through this coat toward the lumen of the vessel come first an internal elastic membrane, then a varying amount of connective tissue and finally a layer of endothelium; the latter is a sheet of single-layered, flat epithelial cells that provide the free surface over which blood flows.

The smallest arteries (those about the thickness of a thread) are called arterioles. The tiniest arterioles are invested with only a scattering of muscle fibres and connective-tissue elements instead of complete coats; such intermediates between arterioles and capillaries are called precapillary arterioles.

In general, arteries are less variable structurally than veins; yet they do specialize in adapting themselves to particular locations and duties.

From a structural standpoint, arteries can be divided into elastic and muscular types, in agreement with the preponderant tissue in their walls. Thus the aorta and its largest main branches are often called elastic arteries; with reference to function these vessels are also termed conducting arteries because they serve chiefly to pipe the blood to the various branches. All other arteries are known as muscular arteries because of their high muscle content; a functional term is distributing arteries, because they not only distribute blood to the various organs and parts but also control systemic blood pressure and the amount of local blood flow.

Vasomotor nerves terminate in the muscular coat of arteries. All but the smallest are nourished in part by minute vessels, the



ADAPTED FROM MAXIMOW AND BLOOM, "TEXTBOOK OF HISTOLOGY"

FIG. 4.—TRANSVERSE SECTION OF A MUSCULAR ARTERY

vasa vasorum, which, however, are confined mostly to the adventitial coat.

Embryology.—Human embryos about four weeks old (five millimetres long) have the rudiments of an arterial system, but these parts still have to undergo considerable change before attaining the final arrangement. A single trunk leaves the heart and breaks into a series of paired loops (aortic arches) that pass upward around the sides of the pharynx and join paired dorsal aortas above that organ.

Elsewhere the originally paired dorsal aortas have fused throughout much of their length into a descending aorta, and this vessel bears serially arranged dorsal, lateral and ventral branches. (*See* also CIRCULATION OF BLOOD.)

Transformation of the Aortic Arches.—The aortic arches of the human embryo are equivalent to the vessels that supply the gills of certain larval and adult vertebrates, but these vessels undergo marked changes before the final pattern is attained. This transformation reflects adaptations pursuant to the acquisition of lungs. Mammals and man have six pairs of arches, although the fifth is inconstant and rudimentary. The first and second pairs disappear soon after their formation and contribute only slightly to the

FIG. 5.—TRANSFORMATION OF THE HUMAN AORTIC ARCHES, ILLUSTRATED IN VENTRAL VIEWS

(A) Model of the full set of aortic arches before transformation begins. (B) Scheme, with the dorsal vessels spread lateral, showing persisting vessels (gray), discontinued vessels (white) and atrophic vessels (stipple)

permanent arterial plan. The dorsal aortas drop out between the third and fourth arches, and this leaves the third arches and the dorsal aortas, continuing into the head, as the internal carotid pathway; when presently an external carotid buds out of each third arch, the internal and external vessels gain a common stem thereafter known as the common carotid. The left fourth aortic

arch persists as the arch of the aorta, and blood from it reaches the descending aorta through the dorsal aorta of that side. The right fourth arch also persists, but serves merely as the stem to a vessel (right subclavian artery) carrying blood to the arm when the right dorsal aorta loses connection with the descending aorta; the left subclavian is a simple branch off the left dorsal aorta. The fifth arches have no derivatives. From each sixth arch a pulmonary artery grows to the corresponding lung. On the right side, the connection with the dorsal aorta involutes; on the left, it continues throughout fetal life as a shunt that permits blood largely to bypass the lungs and reach the aorta; after birth this ductus arteriosus fibroses into the ligamentum arteriosum.

While these changes have been going on, the single truncus from the heart divides into an ascending aorta, connecting with the permanent arch of the aorta on the left, and the right subclavian artery on the right, and into a pulmonary trunk that connects with the paired pulmonary arteries.

Aortic Branches.—The seven highest vessels of the paired series of dorsal branches of the aorta link into a vascular chain known as vertebral arteries; these continue by a single basilar artery and join the internal carotids through the arterial circle beneath the brain. In the thoracic and lumbar regions these vessels become intercostal and lumbar arteries.

Certain lateral branches off the aorta are retained and supply the diaphragm, suprarenal glands, kidneys and sex glands.

The primitive ventral branches disappear, except those that become the unpaired coeliac, superior mesenteric and inferior mesenteric arteries and the paired iliac arteries.

Arteries of the Extremities.—In the arm, the original main line of vessels is the subclavian—brachial—interosseous. The median, ulnar and radial arteries are secondary acquisitions in the order named. Similarly, in the leg, the stem vessel is known as the sciatic artery. Then the external iliac, femoral and anterior and posterior tibials progressively make their appearance. The primitive sciatic becomes interrupted at two levels, leaving the inferior gluteal, popliteal and the peroneal as the sole permanent derivatives. The hand and foot regions are supplied at first by plexuses that are annexed by different vessels in turn.

Comparative Anatomy.—The arterial system of protovertebrates was undoubtedly segmental, but little of this arrangement remains in adult, living vertebrates. These latter animals, in general, tend to send arterial trunks to the various regions of the body rather than supply many small vessels. The arterial plan is relatively stable throughout the several vertebrate classes, and this contrasts with the greater variation in venous patterns. Most striking are the changes in the set of aortic arches; these transformations accompanied the shift from gills to lungs. The arterial system is conveniently considered in three distinctive regions: (1) head and neck; (2) aortic arches (and lungs); and (3) trunk (and limbs).

Head and Neck.—All vertebrates have carotid arteries to the head and brain. In elasmobranch fishes and urodeles (tailed amphibians) these vessels retain a portion of the gill system, but in all higher vertebrates there are paired common carotids, each of which bifurcates into an external and internal branch; the common stems are derivatives of the third aortic arches. The common carotids may pass directly off the fourth arches, may arise by a single stem or may share an innominate origin with the subclavian.

Aortic Arches.—Primitively there were six pairs of aortic arches connecting ventral and dorsal aortas through intermediary gills. This number became reduced progressively, as gills were replaced by lungs, until birds and mammals retain a single complete arch, and on one side only. In fishes the series of vascular arches supplies functional gills, but with the advent of lungs the gills became lost in all but one adult amphibian group. The pattern in other amphibians and in still higher classes of vertebrates relates the third arches to the carotid system, the fourth arches to paired, permanent aortic arches (amphibians and reptiles) or to a single, permanent arch (birds on the right; mammals on the left). The sixth arches give rise to the pulmonary arteries. In urodeles each pulmonary arch continues past the pulmonary artery to the aorta as an open vessel, thus giving rise, beyond the origin of the pulmonary artery, to a ductus arteriosus; a similar condition occurs in one adult reptile only. Birds retain both arterial ducts until after hatching, whereas mammals retain only the left duct during fetal life as a bypass of the lungs.

Trunk.—The aorta proper is single in all vertebrates. It continues into the tail of vertebrates as the caudal artery; in tailless forms this vessel is vestigial, as in man, where it is represented by the so-called middle sacral artery. The arterial branches off the aorta show an essential uniformity of plan in all classes of vertebrates. Small, paired segmental arteries supply the spinal cord, skin and muscles of the trunk. Lateral branches pass to the gonads and kidneys; in lower vertebrates these arteries are more numerous than in higher forms. Unpaired arteries to the visceral organs occur in all vertebrates. In tailward order they are, typically: coeliac trunk, to the stomach-duodenum region superior mesenteric artery, to much of the intestinal tract; inferior mesenteric artery, to the caudal intestine.

All vertebrates possessing pectoral fins or forelimbs have subclavian arteries extending into them. These vessels leave the aorta near the base of the aortic arches in lower vertebrates, but they move up on the functional aortic arches (or arch) as the neck lengthens and the heart moves caudad in higher vertebrates. Paired iliac arteries pass from the aorta into the pelvic fins or hind limbs.

ARTERIES, DISEASES OF. Diseases of the arteries are the most important medical entities in the western world. They cause more disability and death than any other group of troubles. Anatomical evidence of their prevalence has been found in archaeological studies of the earliest human remains.

The commonest form of arterial disease is called atherosclerosis (an early stage of hardening of the arteries, or arteriosclerosis). This consists of a deposition of fatty material in the wall of the artery just below its inner surface. Later, calcium may be deposited in a way that makes the vessel less elastic and unable to dilate when the physiological need arises. The location in the arterial tree and the size of the deposit largely determine the effect on the health of the individual. If the disturbance is present in one or more of the blood vessels supplying the heart muscle with blood (the coronary arteries), it may lead to symptoms that are called angina pectoris (*q.v.*), coronary insufficiency or coronary occlusion. The chief symptom is pain in the chest, often excruciating, and frequently radiating to one or both arms or to the neck.

If the difficulty is chiefly in the arteries supplying the brain, it may lead to paralysis of a part or all of one side of the body (familiarly called a stroke [*q.v.*] or apoplexy), by virtue of the fact that the weakened wall ruptures and causes a hemorrhage into the brain; or a clot (thrombus) may form on the roughened inner surface of the vessel. Much more rarely, this form of arterial disease brings about an insufficient blood supply to the kidneys, with resulting retention of waste products. When it occurs in the arteries supplying the extremities, and particularly the legs, it may result in pain on walking or in the death of tissue (gangrene), requiring amputation.

A great deal of laboratory and clinical research was being devoted in the early 1960s to the study of this form of hardening of the arteries. Researchers believed that it should be regarded as

a disease rather than the inevitable consequence of aging; that it could be forestalled, if not prevented; and that it might even be reversible under certain circumstances. The main lines of attack included dietary studies, with emphasis on the fat and particularly the cholesterol content of the intake of food; the relation of various hormones to the development of the disorder; and other factors too numerous to mention, including the stress and strain of modern life.

High blood pressure (hypertensive vascular disease) eventually results in an organic change in the walls of the smaller arteries. It, too, can be the precursor of coronary, cerebral or renal insufficiency. Its cause is not known in the majority of cases. In certain instances it can be ascribed to various kinds of kidney disease, particularly nephritis. Patients may survive for many years with the commonest form of high blood pressure. One form, however, runs a more fulminating course and results in death in a comparatively short time.

An important, but fortunately decreasing, arterial disease is syphilis of the aorta. Syphilis affects the aorta in one of, or a combination of, three ways: (1) it may weaken the wall of the vessel until it dilates and becomes an aneurysm (*q.v.*); (2) it may weaken it at the valvular ring in a way that produces aortic valvular insufficiency; or (3) it may cause inflammation at the mouths of the coronary arteries in a way that interferes with the circulation of blood to the heart itself. Early and effective treatment of the initial infection will prevent it. It can be arrested by proper treatment at any stage.

When a clot forms some place in the body and travels to another place it is called an embolus. The original clot may be in the systemic veins or in the right side of the heart and travel to a branch of the pulmonary arteries; or it may be originally in the left side of the heart and travel to some branch of the aorta. When it travels to the pulmonary artery, it causes the death of a part of the lung, with resulting pain, cough and the expectoration of blood. When it travels in the systemic arterial tree, it causes symptoms related to the branch in which it lodges. If it goes to the brain, it may cause a stroke. If it goes to the kidney, it may result in pain and the passage of blood in the urine. If it goes to the spleen, it may cause pain in the upper left part of the abdomen. If it goes to an extremity, the limb becomes cold and pulseless, and gangrene may result if it is not treated properly. Very prompt surgery, involving the removal of the freshly deposited clot, is successful in those areas in which it can be performed.

The newest development in this category is the successful surgical substitution of grafts for diseased portions of arteries. These grafts may be arteries properly stored after autopsies or synthetic plastics. The commonest diseases for which they are used are dilatation (aneurysm) or obliteration of the channel by various causes. These may be life-saving measures.

Rarer conditions involving the arteries include inflammation of the walls; hemorrhage into the wall from the little blood vessels that supply the arterial muscles; a specific disease called periarteritis nodosa; and a form of arteriosclerosis involving, primarily, the pulmonary artery (Ayerza's disease). Rheumatic fever affects the arteries more often than is commonly recognized, but since its main scars are left in the heart itself, its arterial manifestations are relatively unimportant. Other rare entities that affect the arterial tree include primary amyloidosis, disseminated lupus erythematosus, scleroderma and dermatomyositis.

See Blood Vessels, Surgery of; Blood Pressure; Thrombosis and Embolism; Tobacco: *Tobacco and Disease*.

(E. B. By.)

ARTERIOSCLEROSIS, or hardening of the arteries, a condition of the arteries in which normal elasticity is lost and the vessel walls become hardened and thickened. *See* Arteries, Diseases of.

ARTESIAN WELL: *see* Well.

ARTEVELDE, JACOB VAN (*c.* 1287–1345), Flemish statesman who formed a federation of Flemish towns and ruled it for the first seven years of the Hundred Years' War (*q.v.*), was born at Ghent of one of the wealthy commercial families of the city. His brother Jan, a rich cloth merchant, took a leading part in public affairs during the first decades of the 14th century. Jacob, who according to tradition was a brewer, spent three years in quietly amassing an extensive fortune. He was twice married, the second time to Catherine de Coster, whose family was of considerable influence in Ghent. Not till 1337, when the imminence of hostilities between France and England threatened serious injury to the industrial welfare of his native town, did he make his first appearance as a political leader. As the Flemish cities depended upon England for the supply of wool for their staple industry of weaving, he boldly came forward as a tribune of the people and, in 1338, at a great meeting at the monastery of Biloke, unfolded his scheme for an alliance of the Flemish towns with those of Brabant, Holland and Hainaut to maintain an armed neutrality in the dynastic struggle. His efforts were successful.

Bruges, Ypres and other towns formed a league with Ghent, in which town Artevelde, with the title of captain general, henceforth until his death exercised almost dictatorial authority. His first step was to bring about the conclusion of a commercial treaty with England. Louis of Nevers, count of Flanders, tried to overthrow Artevelde's power by force of arms but failed completely and was compelled at Bruges to sign a treaty (June 21, 1338) sanctioning the federation of Ghent, Bruges and Ypres, henceforth known as the "three members of Flanders." This was followed, during the year 1339–40 by more treaties which gradually brought into the federation many of the towns and provinces of the Netherlands. The policy of neutrality, however, proved impracticable, and the Flemish towns, under Artevelde, openly took the side of the English, with whom a close alliance was concluded (Jan. 26, 1340). Artevelde now reached the height of his power, concluding alliances with kings and publicly associating with them on equal terms. Under his able administration trade flourished, and Ghent rose rapidly in wealth and importance.

Artevelde's well-nigh despotic rule eventually provoked his compatriots to jealousy and resentment. His proposal to disown the sovereignty of the count of Flanders and to recognize in its place that of Edward, prince of Wales (the Black Prince), gave rise to violent dissatisfaction. A popular insurrection broke out in Ghent, and Artevelde fell into the hands of the crowd and was murdered on July 24, 1345.

S. Lucas, *The Low Countries and the Hundred Years' War 1326–1347* (1929); H. van Werwecke, *Jacques d'Artevelde* (1943); P. Rogghé, *Vlaanderen en het zevenjarig beleid van Jacob van Artevelde*, 2nd ed. (1949).

ARTEVELDE, PHILIP VAN (1340–1382), Flemish patriot, was the youngest son of Jacob van Artevelde (*q.v.*) and godson of Queen Philippa of England, who held him at his baptism. After living in England, where he had been knighted, until 1360, he returned to Ghent and, in 1382, though he had neither military nor political experience, was offered the supreme command by the people of Ghent when they rose in revolt against the count of Flanders, Louis of Male. His name aroused great enthusiasm and his efforts were at first successful. He defeated Louis outside Bruges on May 2, 1382, entered that city in triumph and was soon master of all Flanders. But France took up the cause of the count, and a French army was led across the frontier by the young king, Charles VI, in person. Artevelde advanced to meet the enemy at the head of a burgher army. In the battle of Roosebeke, near Courtrai, on Nov. 27, 1382, the Flemings were routed with terrible loss and Artevelde himself was killed. The brief but stirring career of this popular leader is treated in Sir Henry Taylor's drama, *Philip van Artevelde*.

See P. Rogghé, *Filips van Artevelde* (1947).

ART FORGERY, an object of art by means of which a purchaser is defrauded or the public deceived. The work may have been created for purposes of fraud or it may have been incorrectly attributed as a result of ignorance or expectation of gain. Neoclassical art is deliberately created in imitation of the style or technique of ancient works that the artist believes to be perfect; such neoclassical imitations may later be mistaken for originals or be fraudulently sold as such. In Roman antiquity, for

instance, many imitations or copies of earlier Greek sculptures were produced; some of them were subsequently unearthed by inexperienced antiquarians who could not distinguish a Roman copy from a Greek original. Since the middle of the 18th century, knowledge of the styles, technology and materials of the various periods of classical antiquity slowly improved until such errors of attribution have become relatively rare. Moreover, the particular qualities of neoclassical imitations have come to be appreciated too.

Throughout the middle ages and the Renaissance, imitations of the arts and crafts of classical antiquity were produced in the neoclassical spirit with varying skill and often in new materials. Neoclassical art of the Carolingian renaissance or of the Sicilian court of the emperor Frederick II Hohenstaufen, for example, generally fails to achieve a style pure enough to deceive. Imitations are often marred or embellished by unconscious memories of the styles of intervening periods, especially by Byzantine characteristics that give them a peculiar quality of their own.

Neoclassical imitations of the arts and crafts of earlier periods were produced in great numbers in the far east, especially in China under the Sung dynasty and in Japan in the 18th century. Chinese craftsmen of the Sung, Ming and Ch'ing periods sought to reproduce as exactly as possible, presumably for religious reasons, bronze ritual vessels of the Chou and Shang periods a thousand or more years earlier. A careful analysis of style, technique, qualities of bronze, casting devices and patina, however, usually determines the later bronzes.

Decorative Arts.—It is not as easy as it might seem to detect, by scientific means, frauds or falsifications in the decorative arts or minor antiquities and curiosities, fields in which frauds have always been plentiful. Since the middle of the 19th century frauds of this kind have been offered in great quantities to tourists all over the world. In France, Italy, Germany and England industries were established to cater to the expanding demand for souvenirs; sometimes the wares were even exported to the alleged countries of origin. Nearly all antique-style coffee spoons bearing on their handles the crests of cities throughout the world were manufactured in the German city of Pforzheim; "scarabs" sold in Egypt are often modern products of Bohemia. In some underdeveloped countries native craftsmen still produce pottery of the same materials and according to the same general techniques as those of antiquity, but generally with only a vague understanding of style. However cheap the labour of such craftsmen, in Tunisia, Egypt or Mexico, their modern imitations are often more expensive than the genuine pieces recovered in large quantities in excavations. Modern copies can generally be recognized because of errors of style or materials. The faking of antiquities has spread far and wide, even in fields of primitive art, African, American Indian, Polynesian and others.

In the field of European porcelain, more pieces of false Sèvres are known to exist than the Sèvres factory can have produced. Meissen and Capo-di-Monte ware have likewise been copied in massive quantities, often with little knowledge or skill. Shortly before World War II, U.S. and South American stores were flooded with cheap Japanese imitations of English Wedgewood ware. Far eastern porcelains have also been widely imitated or copied with the intention of defrauding, both in Asia and in Europe. Customs regulations requiring that the country of origin of all modern wares be clearly marked on them have done much to reduce this traffic, which is also threatened by legislation for the protection of trademarks, original designs and models. Many imitations, however, are already antiques which have a recognized artistic or commercial value of their own. Several museums own collections of antique "fakes" which illustrate the history of taste, including various misconceptions of styles and techniques. Instructive in this respect are 18th-century European imitations of far eastern porcelain, such as the earliest pieces of Meissen ware, the French second empire imitations of 18th-century Sèvres and the very lush imitations of rococo wares produced in the latter part of the 19th century for the court of Ludwig II of Bavaria.

Faked antique furniture has been produced extensively and profitably. Fragments of genuine old pieces together with timber, nails or marble salvaged from wrecked houses can be made relatively convincing antiques. Many of these pieces [illegible] ever be treaks it genuine, since they were manufactured [illegible] the tastes and requirements of an age different from th[illegible] they are attributed. In the 18th century, for instance, [illegible] tables were not in use, yet thousands have been put together of old bits and pieces and sold as genuine antiques. Many [illegible] early 19th-century desks are likewise doctored pianofortes. [illegible] French manufacturer of faked antiques has boasted in his [illegible] of his ability to produce forgeries convincingly defaced by [illegible] wormholes or excrements of flies. (*See* also ANTIQUE.)

Fine Arts.—Unsigned drawings in the general manner of a well-known old master are frequently attributed to the master himself and then offered on the market as such, though they [illegible] well be works of his minor contemporaries or pupils or even late copies of originals. Genuine old drawings by students who have carefully copied an authentic original or a print are sometimes mistaken for lost originals; many experts are therefore suspicious of all "finds" that have an obscure history and cannot be traced to their attributed source.

From the 16th century until the latter part of the 19th century European painters and sculptors spent much time, especially in their youth, carefully copying works of older masters. Géricault's early drawings and paintings include many studies after Rubens or Caravaggio; one such Géricault study, in a provincial French museum, was erroneously attributed to Rembrandt.

Many museums have inherited, especially from 19th-century collectors, legacies in which a majority of the attributions have been proved to be incorrect. In some cases, a work is proved to be that of another master; more often, old copies, once mistaken for originals, are weeded out. A famous work attributed to Murillo in the Vatican collections, a gift of the Spanish royal family, was proved by an X-ray examination to be painted over a work of a later period than that in which Murillo lived. Sometimes, however, an old copy turns out to be the only record of a lost [illegible] particularly in the case of masterpieces of very early [illegible] painting.

The attributions in most 19th-century collections of [illegible] and sculptures of the Italian Renaissance were, on the [illegible] erratic. Through the work of such connoisseurs as Bernard Berenson experts in this difficult field have become far more [illegible] in their attributions, though even Berenson, in later years, [illegible] the honesty and courage to correct a great number of his [illegible] attributions.

In spite of great progress during the 20th century [illegible] attributions of unsigned works of old masters remain [illegible] The working habits of some masters made the task of [illegible] tribution particularly complex. It has been remarked [illegible] were more paintings by Camille Corot in U.S. coll[illegible] than Corot had ever painted. Corot was, however, a prolific [illegible] often producing several exquisite small oils in a single day [illegible] sides he was at one time surrounded by numerous a[illegible] whose works he frequently corrected with a few bro[illegible] his own, he sometimes playfully added his own sign[illegible] an impecunious student might sell it. It was the pr[illegible] earlier masters, such as Rubens, to allow their students to [illegible] the background and draperies of a major commiss[illegible] the master contributed only the final touches to an e[illegible] of one of his original sketches.

A brisk trade has developed in works of minor French [illegible] painters fraudulently attributed to major masters. The [illegible] on an early riverbank scene by Maximilien Luce [illegible] removed to make the picture look like an unsigned [illegible] Gauguin's signature is also known to have been added [illegible] of unsigned works by his friends, associates and [illegible] Pont Aven art colony. In Rome, in 1958, what was th[illegible] a major work by Amedeo Modigliani, at the Galleria Nazionale d'Arte Moderna, which had paid a high price for it, was [illegible] to be most probably the work of Modigliani's friend M[illegible] an excellent artist who, at one time, used the same [illegible] Modigliani and often painted in almost the same style [illegible] of real intrinsic quality, false attributions can be corrected [illegible]

…; may be reduced in current market value. In the case of …tored works, another problem arises: many badly dam… inferior originals have been brilliantly restored to look … of far greater artistic and commercial value. The connective tissues comprise the …lages, ligaments, tendons and muscles that form the … tissues of the body and permit motion. Each joint … the articular ends of the bones concerned; the articular … which provide glassy-smooth coverings over the bony … capsule, which forms a strong envelope about … and the synovial membrane, a soft lining tissue that … surface of the capsule. In addition, each joint … nerves and blood vessels, tendons and muscles that pro…vide motive power and a small amount of viscous synovial fluid that lubricates the gliding surfaces. Many articulations, such as those of the fingers and the knee, are typical hinge joints in that they permit motion in one plane only. At the other extreme of joint action are the shoulders, hips, wrists and ankles, all constructed on the principle of the ball and socket, which permit motion in all directions. Between these types are various modifications such as the elbows, which permit rotation, and the temporomandibular joints of the jaw, which permit side to side motion in addition to hinge action. Another type of articulation is that illustrated by the sacroiliac joints of the pelvis; these merely connect bones and allow little or no motion between them. Nevertheless, these synarthrodial articulations may be the site of arthritis. The various ways the different forms of rheumatic diseases affect the articular tissues are discussed below in the descriptions of the individual diseases.

The length of time that man and other creatures have been plagued by illnesses is largely speculative in most instances. In the case of at least one form of arthritis, however, it can be stated with assurance that the ravages of illness have been felt for at least 100,000,000 years, for unmistakable evidence of osteoarthritis has been found not only in the skeleton of a Neanderthal man dating from about 40,000 B.C. but also in dinosaurs of the Mesozoic period.

Of far greater practical significance, however, is the importance of arthritis and rheumatism today. Since physicians are not required to report these diseases to public health statistical collection agencies, exact data as to their incidence are not available. Nevertheless estimates have been attempted. A survey published in 1938 under the auspices of the U.S. public health service led to the conclusion that more than 6,500,000 people in the U.S. were then victims of some form of rheumatic disease. This figure was larger than similar estimates for heart diseases, cancer, tuberculosis, and nervous and mental disease combined. A public health service survey published in 1952 raised the estimated number of people over the age of 14 suffering from these diseases to more than 10,000,000, and unquestionably this figure rises as the population increases. Data from the 1938 survey indicated that arthritis and rheumatism caused more than 97,000,000 days of time lost to gainful occupation—an economic loss to the nation greater than that from strikes and walkouts combined over the same period of time. When one adds the wages lost by the patient and individual and public funds spent for care, the cost must be reckoned in excess of $1,500,000,000 annually in the U.S. alone. Even this figure, however, takes no account of the still more serious toll exacted by these diseases in terms of human suffering and broken lives.

In the succeeding paragraphs individual rheumatic diseases will be briefly considered under the following headings:

1. Arthritis caused by known microorganisms
2. Rheumatic fever
3. Rheumatoid arthritis
4. Ankylosing spondylitis
5. Arthritis accompanying psoriasis
6. Arthritis accompanying ulcerative colitis
7. Arthritis accompanying foreign protein reactions
8. Degenerative joint disease
9. Gout
10. Traumatic arthritis
11. Neurogenic arthritis
12. Neoplasms of joints
13. Collagen diseases
14. Nonarticular rheumatism
15. Miscellaneous forms of joint diseases

Arthritis Caused by Known Microorganisms.—Prior to the introduction of sulfonamides and penicillin, arthritis caused by the invasion of bacteria into the joints was a serious problem. The pyogenic (pus-forming) cocci were the usual bacterial agents responsible, of which the most common were the gonococcus, pneumococcus, hemolytic streptococcus and staphylococcus. The pus produced in response to infection by these cocci has the property of eroding articular cartilages. Since the latter have almost no

capacity to regenerate after sustaining damage, such infections usually caused serious and permanent harm. Other intra-articular tissues were damaged also and the joint was ultimately left with injury varying from moderate disability to complete bony fusion (ankylosis), depending on the severity of the infection. Happily this formerly serious problem has become comparatively minor since the introduction of modern antibiotics, for the infections can be controlled in most instances before permanent damage has been caused.

Arthritis caused by a particular microorganism, the tubercle bacillus, deserves special mention. This germ causes a less acute and less rapidly destructive type of articular infection than do the pyogenic cocci, but one that is extremely stubborn. Antibiotic therapy may be insufficient in tuberculous arthritis, and surgical procedures designed to fuse the joint and thus give complete rest may be required as well.

Rheumatic Fever.—Rheumatic fever causes an extremely acute and painful type of arthritis that usually affects multiple joints and is referred to as migratory because it tends to move from one joint to another. The inflammation persists only a few days or weeks in any one joint and invariably subsides without leaving residual damage since it affects primarily the synovial membrane and does not injure the articular cartilage nor lead to scarring around the joint. Unfortunately, however, the disease often results in serious and permanent damage to the heart. Hence, although the arthritis is extremely painful, this manifestation is of relatively minor importance in the total disease picture. It has been generally well established that rheumatic fever does not occur without a preceding hemolytic streptococcal infection of the throat but the exact mechanism of causation is not known. Aspirin and other salicylates as well as the powerful corticosteroid drugs cause prompt and complete relief of the arthritis. Unfortunately, however, they appear to have very little beneficial effect on the lesions in the heart, and involvement of this vital organ demands rest in bed for weeks or months until cardiac inflammation has subsided. Fortunately, the disease can be prevented from recurring in patients who have once had it by preventing further hemolytic streptococcal infections through the continual administration of penicillin or sulfonamides over periods of years.

Rheumatoid Arthritis.—Rheumatoid arthritis is a chronic, generally progressive disease involving multiple joints and frequently associated also with mild or moderate fever, general debility and other manifestations such as nodules under the skin and inflammation of the eyes. Synonyms for rheumatoid arthritis no longer used are: chronic infectious arthritis, atrophic arthritis and arthritis deformans. Of all the rheumatic diseases this is the one that causes the most severe crippling. Among approximately 10,000,000 patients in the U.S. with rheumatic diseases in the 1950s, an estimated 25% of that total had rheumatoid arthritis. Yet because of the many years the average rheumatoid arthritis case persists and the severe disability it causes, these patients probably accounted for a very large proportion of the total "man days" lost as result of all types of joint diseases.

As the name implies, rheumatoid arthritis resembles rheumatic fever in some respects. Indeed when its onset is particularly acute it cannot be easily distinguished from the latter disease except by observing the course of illness for several weeks. However, the average attack of rheumatoid arthritis is not acute, and the joint involvement customarily persists for months and years instead of subsiding in a few days or weeks as does that of rheumatic fever. The heart may be involved in rheumatoid arthritis but in contrast to rheumatic fever this is a rare and usually not serious manifestation.

Damage to Joint.—The disease process within the joints apparently begins as inflammation of the synovial membrane. This sometimes may be fairly acute, but characteristically the onset is insidious and the disease moderate in intensity and chronic from the outset. In either case there is an increase in the amount of synovial fluid, which becomes less viscous. The involved joints are tender and the range of motion is limited by pain. Swelling is contributed to by the increased fluid, thickening of the synovial membrane and frequently by inflammation of the capsule and surrounding tissues. If the disease subsides at this stage the [illegible] can return to an essentially normal state, and this often [illegible] after a period of weeks or months during the first few [illegible]. Eventually, however, and commonly from the outset, the [illegible]mation becomes one of a continuous, chronic type with considerable proliferation of the synovial membrane. A feature of the [illegible] is the growth of thin sheets of inflammatory tissue over the surfaces of the articular cartilages from their periphery toward the center. This tissue has the capacity to erode articular [illegible] in the fashion previously described for the action of pus. When this occurs, irreparable damage begins. The amount of ultimate articular disability that will remain after the pain of inflammation has subsided depends largely on the amount of injury sustained by the cartilages. If it is slight, articular function can return almost to normal. If injury is severe, large areas of the articular bony surfaces may be denuded of cartilage. This leads to the formation between the ends of the bones of adhesions and scar tissue, which in turn can be transformed into bone with resultant complete immobility of the joint. In other instances loss of cartilage and the erosion of bone margins coupled with destruction of ligaments can result in instability and dislocation of bones within the articular capsule.

Other Diagnostic Features.—Several other very characteristic features of rheumatoid arthritis help establish the diagnosis. The two most important are subcutaneous nodules and the so-called rheumatoid factor. The nodules are firm connective tissue masses about the size of almonds that occur in approximately 20% of patients at some stage of the disease. They usually are just distal to the elbow on the extensor surface of the arm. They do no harm although they often indicate a rather severe type of disease. The rheumatoid factor, a component of the gamma globulin fraction of the blood, can be detected by certain agglutination tests and occurs almost exclusively in patients with rheumatoid arthritis. Hence it has great diagnostic value. Other diagnostic features are the great tendency for joint involvement to be symmetr[illegible] the two sides of the body and the "early morning stiffness" that patients experience on first waking, which may persist for [illegible] hours after rising.

Rheumatoid arthritis occurs in women more frequently than in men in a ratio of two or three to one. The onset is [illegible] between the ages of 18 and 50, but it also occurs in chil[illegible] is not rare among those of advanced years. It apparently occurs in all climates and affects all races.

The cause of rheumatoid arthritis has not yet been d[illegible]. Attempts to isolate bacteria and viruses from the blood [illegible] fluid or tissues have been unsuccessful. Dietary factors [illegible] shown to play no causative role. When the important [illegible] was made in 1949 that cortisone, a hormone of the adrena[illegible] greatly benefits the pain and disability of the disease, [illegible] thought that rheumatoid arthritis might be due to an a[illegible] of adrenal cortical function. Subsequent research, howe[illegible] not bear this out.

Treatment.—In view of the lack of knowledge as to the cause of rheumatoid arthritis, it is not surprising that no treatment has been found that will effectively control the disease. Neve[illegible] much can be done to make the patient more comfo[illegible] to minimize ultimate crippling. Of chief importance in [illegible] trol of pain and disability are the salicylates, such as [illegible] which may be taken in far larger doses than ordinar[illegible] headache. If salicylates alone are not sufficient, [illegible] of the corticosteroids may be added. These hormones [illegible] most powerful anti-inflammatory agents yet discovered [illegible] acute, potentially fatal diseases of short duration, doses [illegible] large to control symptoms must be used. However, [illegible] costeroids are themselves potentially dangerous and the[illegible] used sparingly in a nonfatal disease like rheumatoid a[illegible] which it can be expected that treatment must be conti[illegible] months or years.

Of no less importance in treatment are corrective exercises designed to minimize muscular atrophy and to prevent [illegible] velopment of deformities. These measures are undra[illegible] tedious for the patient, but if adhered to faithfully they ca[illegible]

... ultimate benefit. Even in patients who have already ... crippling deformities, these corrective exercises can ... ded, although sometimes they must be coupled ... orthopedic measures or operations in the case of the ... disabilities.

Arthritis Accompanying Ulcerative Colitis.—Another ... disease often considered to be rheumatoid arthritis ... occurs in approximately 15% of patients with ulcera... serious disease of the large intestine. In roughly ... of the cases the joint disease is clinically indistinguish... ankylosing spondylitis, while in the other three-fourths ... of the extremities are affected. These patients ... rheumatoid factor and the peripheral joint involve... from that of rheumatoid arthritis in usually being ... The arthritis tends to improve as the colitis improves ... corticosteroid therapy.

Arthritis Accompanying Foreign Protein Reactions.— ... days of serum therapy it has been observed that a ... portion of patients receiving antiserums prepared ... developed urticaria (hives) and transient but pain... Antiserums are now much less commonly used, but ... occasionally have similar reactions following the use of ... such as penicillin or insulin. These reactions ... with corticosteroids and are usually of little ... except for the fact that henceforth those patients ... given the offending agent.

Degenerative Joint Disease.—This disease is also called ... degenerative joint disease is the preferred term ... the underlying process. Other synonyms no... hypertrophic and senescent arthritis. In contrast ... arthritis, which is an inflammatory disease starting ... membrane, osteoarthritis is primarily a degenera... beginning in the articular cartilage. Microscopic ... the cartilage occurs in many people in the third ... However, symptoms rarely occur before the age ... and many people experience no significant disability even after the age of 70. When degeneration of cartilage becomes advanced, large areas of the articular bony surface may become denuded of cartilage. In addition, bony projections (osteophytes) grow out from the margins of the bones and may cause mechanical interference with motion. There is no doubt that wear and tear of daily life plays a part in this disease but it is not the sole causative factor.

The reasons for the various degenerative changes in the body that occur with advancing age are poorly understood. In the case of articular cartilage, however, at least two factors are apparent. First, the arrangement by which these structures are nourished is less efficient than that of most tissues since they have no blood supply and must absorb their required metabolic materials from the synovial fluid that bathes them. Second, as has been noted previously, articular cartilage has very limited capacity to regenerate. Another factor of importance in some types of degenerative joint disease is that of heredity. This is especially notable in the case of the so-called Heberden's nodes involving the terminal joints of the fingers.

The name primary osteoarthritis is sometimes given to the form of the disease that appears, usually quite benignly, in multiple joints with advancing age. When only one or two joints are involved, the osteoarthritic process usually is a secondary one occurring in a joint made more susceptible to wear and tear by some structural abnormality, previous injury from an accident or an inflammatory type of arthritis. Most people who have osteoarthritis have few or no symptoms; the articular changes are often discovered incidentally in X-rays ordered because of other conditions. Among persons who have symptoms the disability is mild in most, moderate in some, crippling in very few. Some affected joints are often painful for a while but later are painless. Few if any constitutional reactions accompany the disease, which is essentially limited to joints and does not affect other tissues or body systems except for some associated transitory stiffness of musculotendinous structures. The condition should be regarded in most instances merely as one of the annoying but minor disabilities of advancing years.

Because in osteoarthritis synovial membranes are not inflamed, no permanent stiffness or fixation (ankylosis) occurs. Thus, a chief remedy is reassurance for the patient that he does not have one of the progressive, crippling forms of arthritis or one likely to cause serious disability. Moderation in the use of affected joints, their protection from undue irritation (including that from excessive weight bearing in obesity) and the philosophic acceptance by the patient of a somewhat lowered level of physical activity are sometimes the only measures required to obtain comfort. Application of heat, other physical remedies and the use of mild analgesic drugs such as aspirin often are helpful. Only in the case of hip involvement is osteoarthritis apt to be significantly disabling. In the few patients in whom crippling is severe, much benefit often can be obtained from various surgical procedures.

Gout.—Gout is a disease of abnormal uric acid metabolism characterized by acute episodes of arthritis and, in later stages, by urate deposits (tophi) around bones and joints. In spite of its known relationship to uric acid, the exact nature of the metabolic defect is not understood. Men are more subject to gout than are women in a ratio of approximately 19 to 1, and hereditary influences are important. Persons with gout habitually have more uric acid in their blood than do unaffected people, and a significant number of their blood relatives do also even though they are free of symptoms. The involved joints are exquisitely painful and tender, and are swollen and red. The disease has especial predilection for the basal joint of the great toe, but this joint is by no means always involved.

During the early years of a patient's history of gout, the attacks occur suddenly, last a few days to weeks and subside without leaving any disability. After a number of years of repeated acute attacks the disease passes gradually into the chronic or tophaceous stage during which the deposition of urate crystals produces defects in articular cartilages and bones. From this time on, the disability remaining after each attack increases, and severe crippling can ultimately occur if the disease is unchecked.

Fortunately the acute attacks can be effectively controlled by colchicine, derived from the plant colchicum, and by the anti-inflammatory drugs; and the ravages of chronic gout can be prevented by so-called uricosuric drugs that increase the urinary excretion of uric acid. Special diets low in foods that produce uric acid formerly were an important part of the therapeutic regimen, but it is no longer considered necessary for most patients to adhere to them rigidly.

Traumatic Arthritis.—Trauma to joints can produce injuries ranging from simple sprains—small tears in ligaments and tendons caused by violent overstretching—to serious mechanical derangements of intra-articular structures and fractures of bones extending within the joint capsule. Milder lesions require no more than adhesive strapping or the application of plaster casts to insure local rest and protection against further injuries during healing. More severe disabilities may require operations for the repair or removal of damaged structures such as ligaments and cartilages, or for the pinning of broken bones.

Neurogenic Arthritis.—A very destructive disorder of joints can result from diseases or injuries of the tracts in the spinal cord and peripheral nerves that carry sensory stimuli from the extremities. Probably these disruptive lesions represent an exaggerated form of combined degenerative joint disease and traumatic arthritis occurring in joints made prone to repeated injury by lack of pain sense, and awkwardly used because of absent tactile and position sense.

Neoplasms of Joints.—Neoplasms of joints may be benign and produce symptoms merely by their local encroachment on space, or they may be malignant and capable of sending cancerous metastases to other parts of the body. Neither type is common. Benign tumours may or may not require removal depending on their size, location and significance of symptoms. Malignant tumours always demand prompt surgical opinion as to the best means of treating them.

Collagen Diseases.—The so-called collagen diseases comprise a group of usually serious illnesses involving connective tissues in blood vessels widely spread throughout the body in synovial membrane, skin and internal organs. Included in the collagen diseases are systemic lupus erythematosus, polyarteritis (periarteritis) nodosa, dermatomyositis and scleroderma. Rheumatoid arthritis and rheumatic fever also are commonly considered to belong to this group. Transient or more chronic arthritis is common, and many patients show features that overlap those of rheumatoid arthritis. In the past these diseases were thought to be usually fatal, but it is now recognized that they may frequently run a relatively benign course and that even in severe cases many patients show great improvement, especially since the introduction of corticosteroid drugs.

Nonarticular Rheumatism.—This important group of disorders comprises a wide variety of complaints in which pain is felt in ligaments, tendons, bursas, muscles and other connective tissues outside the joints. Such pain does not necessarily reflect inflammation within those structures but may represent pain referred to them by sensory nerves that supply them and are irritated at a higher level. This diversified group of disorders is represented in the largest segment of patients with rheumatic diseases. Fortunately, however, these disorders ordinarily persist in severe form only a few days or weeks and hence are seldom permanently disabling although they may force a change of occupation.

When the complaints can be traced to painful tissues they take their name from the structure involved—tendinitis, bursitis and myositis (inflammation of muscle). When complaints are widespread the descriptive term fibrositis is often used to indicate generalized pain in fibrous connective tissue without designating a particular location. Little is known about the appearance of the lesions in the tissues or about the causes. The bursas, which are flattened, balloonlike structures containing small amounts of viscous fluid, are situated deep in the soft tissues overlying bony prominences and act as cushions. Inflammation in the bursas usually is secondary to inflammation in the tendons that underlie them.

A very common cause of referred pain to muscles of the shoulders and arms is degeneration of the intervertebral discs that act as cushions between the individual vertebrae of the spinal column in the neck. Secondary to this, bony outgrowths develop from the margins of the vertebrae. As a result, the large sensory nerves that leave the spinal cord between each pair of vertebrae may become irritated and cause pain in the structures they supply. Similar changes in the lower spine can cause pain referred to the buttocks and thighs, or throughout the entire distribution of the sciatic nerve, causing the syndrome of sciatica.

There is some evidence that vague painful states in fibrous tissue and muscles can result, in susceptible individuals, from stimuli arising from the brain due to anxiety and other emotional problems. Such painful states are called psychogenic rheumatism, but the mechanism is not understood nor, indeed, is it certain that such a mechanism exists.

Most forms of nonarticular rheumatism respond well to aspirin or corticosteroids and are benefited by local warmth, massage and exercise.

Miscellaneous Forms of Joint Diseases.—The foregoing types of diseases that affect the joints include those of greatest importance, but there are many others, including the following: hemophilic arthritis, which results from repeated bleeding into the joints of hemophiliac patients (bleeders); various degenerative disorders of unknown cause occurring in young individuals of which osteochondritis dissecans is an example; aseptic necrosis of bone, which results from obstruction to the blood supply such as may occur in caisson disease because of air bubbles in the blood stream; Reiter's disease, a form of arthritis of unknown cause associated with inflammation of the urethra and eyes and often also with diarrhea and skin lesions; and intermittent hydrarthrosis, a disease of obscure cause characterized by periodic episodes of effusions of fluid into the joints.

ARTHRODIRE, fishes common about 300,000,000 years ago but extinct for the last 230,000,000 years. The head and thorax were covered by a bony shield; the rest of the body was naked. *See* PLACODERM.

ARTHROPODA, the largest phylum of the animal kingdom, forming about three-quarters of the known species of animals. In size arthropods range from the tiny parasitic mite *Demodex*, less than 0.1 mm. in length, to the giant Japanese crab *Macrocheira*, which has a leg span of 11 ft. Fossil Eurypterida, aquatic in habit, reached a body length of nearly six feet.

Arthropods occur in every conceivable habitat, from the deepest seas (crustaceans and pycnogonids) to an elevation of 22,000 ft. on Mt. Everest (spiders), from north polar waters to far in the antarctic continent (Collembola) and as external and internal parasites on other animals.

The phylum includes: the insects (class Insecta); spiders, mites, scorpions, etc. (Arachnida); crustaceans (Crustacea); centipedes (Chilopoda); millipedes (Diplopoda); and other less familiar groups—Symphyla, Pauropoda, Onychophora, Merostomata (which includes the Xiphosura and Eurypterida).

The insects (*q.v.*), which dominate the land, are of economic importance both as pests and as beneficial pollinators of crop plants; they alone among invertebrates are capable of flight, by one or two pairs of wings. Spiders, mites, scorpions and other arachnids (*q.v.*) also live on land and are found in many millions per acre of arable country; they comprise the majority of the invertebrate carnivores and are therefore of great importance to other animals. Crustaceans (*see* CRUSTACEA) are abundant in salt and fresh waters; they are of great economic importance in marine food supplies and serve as food for other invertebrates, fishes and whales. Centipedes, millipedes, symphylids, pauropods and onychophorans are all land dwellers restricted to damp habitats; they are of little economic importance (*see* CENTIPEDE; MILLI-

Tardigrade, or water bear, cl[illegible] Tardigrada, a free-living form found on vegetation, in sand, fresh water and even [illegible] sea. The largest are not much more than 1 mm. in length; most of them are mu[illegible]ler

Red centipede (*Otocrypt*[illegible] *sp*[illegible]*nosus*), class Chilopoda, a land-dwelling arthropod found throughout the world in damp locations. Feeding on live prey, it poisons victims with venom from glands in its first pair of legs, which serve as jaws. Centipedes range in length from 3 mm. to almost 1 ft.

Millipede (*Narceus americanus*), class Diplopoda. Like the centipede, it lives in moist places; during the dry season it is found at considerable depths in the soil. It feeds primarily on decaying plants. Millipedes vary in length from about 2 mm. to 1 ft.

Wolf spider (*Dolomedes sexpunctatus*), class Arachnida, feeding on a minnow captured by diving below the surface

Horseshoe crab (*Limulus polyphemus*), class Merostomata, a marine arthropod that lives in shallow water and feeds on worms and mollusks. Extremely ancient in origin, horseshoe crabs often are called "living fossils." Their maximum size is about 2 ft.

FIG. 3.—EXTERNAL FEATURES OF THE CLASSES ARACHNIDA AND SYMPHYLA

(Left) Scorpion (class Arachnida) showing preoral chelicerae and united cephalothorax bearing eyes and legs (length 100 mm.); (right) *Scutigerella immaculata* (class Symphyla) showing preoral antennae and defined head. Each trunk segment bears a pair of legs (length 4 mm.)

As in vertebrates, the skeletal muscles of arthropods are "striped." The fine structure and the properties of the striped muscles vary; some contract slowly, but the flight muscles of a fly can twitch 330 times per second. If the movements caused by a muscle are rapid and large, they cannot also be strong. Much of the complex anatomy of arthropods meets one or the other of these two incompatibles, depending on the different ways of living. Slow rhythmical movements of the alimentary canal are mediated, as in vertebrates, by "unstriped" muscle.

Organ Systems and Function.—Besides possession of an exoskeleton, another outstanding characteristic of the Arthropoda, one not primarily associated with the metameric segmentation just described, is the form of the blood system. No fine vessels, such as the capillary nets of worms and vertebrates, are present. A dorsally situated heart discharges its blood into main arteries, most of which lead ultimately into large vascular spaces (collectively, the haemocoel) that bathe the organs. These vascular spaces replace the coelomic body cavity of vertebrates and worms. Blood returns to the heart via a pericardial blood space and enters by paired ostia, which open to receive blood and then close while the heart is contracting and forcing blood into the arteries. Arthropod blood may be red, green, blue or colourless, according to the presence and nature of respiratory pigments. These pigments, comparable with the red hemoglobin of human blood, increase the carrying or the storage capacity of the blood for oxygen.

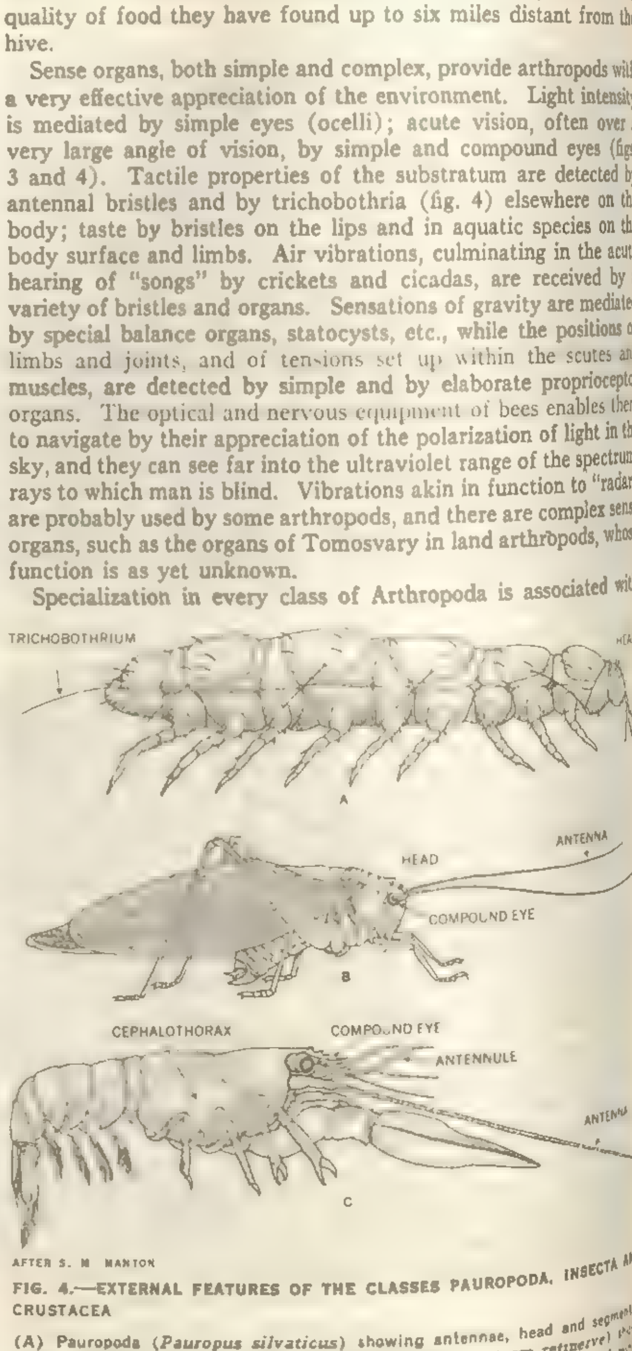
The alimentary and nervous systems are not unlike those of other segmented invertebrates, but both systems may be more elaborate and specialized for various purposes. The mouth leads into an ectodermal pharynx that may be armoured and very elaborate. The mid-gut that follows is usually the seat of digestion and absorption of food. The hind-gut, also ectodermal, may be long or short and usually absorbs water, so consolidating the feces. In terrestrial arthropods Malpighian tubules, often present at the junction of hind- and mid-gut, absorb waste material from the blood spaces that bathe them. The tubules discharge (often crystalline uric acid in the insects) to the hind-gut, thus reducing water loss. There may be special devices for drawing in fluid food, for internal-chewing (trituration) and for the production of digestive juice.

The nervous system, as in annelid worms (*see* ANNELIDA), consists of paired ventral nerve cords with paired ganglionic swellings in each segment. From the ganglionic swellings segmental nerves pass out to the limbs and organs. Anteriorly, a dorsal supra-esophageal "brain," which innervates the eyes, is united by circum-esophageal commissures with a subesophageal ganglionic mass often representing the fused ganglia of the immediately postoral segments. The antennal ganglia are primarily postoral, but more often become preoral and associated with the supra-esophageal brain during embryonic development.

The great range of arthropodan sense organs exceeds those of all other invertebrates and makes possible varied and precise responses. The considerable powers of transmission of information by some arthropods resides in the acuity of their sense organs and in their nervous equipment. For example, bees can transmit information to other bees in a hive as to the direction, distance and quality of food they have found up to six miles distant from the hive.

Sense organs, both simple and complex, provide arthropods with a very effective appreciation of the environment. Light intensity is mediated by simple eyes (ocelli); acute vision, often over a very large angle of vision, by simple and compound eyes (figs. 3 and 4). Tactile properties of the substratum are detected by antennal bristles and by trichobothria (fig. 4) elsewhere on the body; taste by bristles on the lips and in aquatic species on the body surface and limbs. Air vibrations, culminating in the acute hearing of "songs" by crickets and cicadas, are received by a variety of bristles and organs. Sensations of gravity are mediated by special balance organs, statocysts, etc., while the positions of limbs and joints, and of tensions set up within the scutes and muscles, are detected by simple and by elaborate proprioceptor organs. The optical and nervous equipment of bees enables them to navigate by their appreciation of the polarization of light in the sky, and they can see far into the ultraviolet range of the spectrum, rays to which man is blind. Vibrations akin in function to "radar" are probably used by some arthropods, and there are complex sense organs, such as the organs of Tomosvary in land arthropods, whose function is as yet unknown.

Specialization in every class of Arthropoda is associated with



AFTER S. M. MANTON

FIG. 4.—EXTERNAL FEATURES OF THE CLASSES PAUROPODA, INSECTA AND CRUSTACEA

(A) Pauropoda (*Pauropus silvaticus*) showing antennae, head and segmented trunk (length 1 mm.); (B) Insecta, katydid (*Microcentrum retinerve*) showing antennae, head, thorax bearing three pairs of legs and two pairs of wings and abdomen; (C) Crustacea, lobster (*Homarus vulgaris*) showing antennules, antennae, united cephalothorax and abdomen with limbs

elongation of limbs and a reduction in their number on the hinder body segments. Along with this specialization there is a tendency toward concentration of the primitive ladderlike trunk nervous system.

The sclerotization of the surface of many arthropods restricts the access of air to the tissues by direct diffusion. Aquatic arthropods, except the smallest, usually respire by means of gills, thin-walled projections from the body containing a copious blood circulation. Wood lice and scorpions, for example, breathe by means of air-filled chambers, the walls or processes of which are vascular; the majority of land species, however, utilize tracheae, fine air-filled tubes opening on the body surface and ending within tissue cells. In tracheate arthropods blood does not transport the respiratory gases as it does in the majority of animals. Tracheae differ in structure from class to class and have doubtless been evolved independently several times during arthropodan adaptation toward land life. Carbon dioxide is eliminated from the general body surface, gills and tracheae, and nitrogenous waste matter is excreted by segmental excretory organs (some of which are converted to salivary glands), by Malpighian tubules and even by the mid-gut (*Peripatus*).

The sexes are usually separate, but there are many cases of hermaphroditism. Reproductive organs and accessory glands may be very complex, but there is generally a single external genital opening or one pair of openings. Copulation is usual but not invariable, the eggs being fertilized in the female genital tract or externally just as they are laid. Great egg production (fecundity) characterizes many arthropods, particularly some crustaceans and insects. Enormous numbers of lightly yolked eggs may be produced that quickly hatch into larvae; these larvae feed, grow, molt many times and eventually assume the adult form. In some arthropods a few heavily yolked eggs are laid; these eggs, protected by a good shell or by parental care, may hatch as miniature adults. The time interval between one generation and the next may be three days or less in some insects and small crustaceans, so that one pair, or one parthenogenetic female (reproducing without fertilization) may give rise to several millions of descendants in a few weeks. By contrast, well-armoured large arthropods, such as the lobster, become sexually mature at the age of four years and breed only every other year.

The form of the mouth-parts (segmental head appendages) and trunk limbs of arthropods is enormously diverse, serving many different ways of feeding, running and swimming. In aquatic forms many ways of filtering food from the water exist, performed by head limbs alone or by trunk limbs in addition. Limbs also provide offensive, defensive and copulatory aids and may bear the respiratory surfaces. A limb that is basically two-branched (biramous) occurs in the Crustacea, Trilobita and Merostomata, while unbranched (uniramous) limb characterizes the Onychophora, Diplopoda, Chilopoda, Pauropoda, Symphyla and Insecta.

Evolutionary History.—The past history of the arthropods and the relation of one class to another can only be deduced from comparative anatomy, embryology and functional studies since recognizable fossils are not sufficiently ancient. The terrestrial arthropods, that is, the Onychophora, Pauropoda, Diplopoda, Chilopoda, Symphyla and the various hexapod groups (Apterygota and Pterygota insects) appear to be a related series of classes. Basic similarities shared among these classes contrast with the characteristics of Trilobita, Merostomata, Arachnida and Crustacea.

A differentiation of habits in very similar environments appears to have been of paramount importance in the evolutionary differentiation of the former series of terrestrial groups: the Onychophora retain a soft body wall, unstriated muscle, etc., in association with an extraordinary power of deforming the body and of squeezing through cracks impassable to predators; the centipedes have evolved the carnivorous habit and a body form that allows fast running; the millipede construction enables these forms to burrow by the motive force of their legs; the Symphyla gain cover in the leaf mold and decaying wood by twisting and turning their delicate bodies in narrow spaces, but not by pushing, and their anatomy serves this purpose.

A reduction in the number of legs and an increase in leg length brings many mechanical advantages and, like the compound eye, has been independently acquired many times by different groups of arthropods. There is little doubt that the Merostomata and Arachnida are related; they are often grouped together as the Chelicerata because they share the chelicerate nature of the first pair of legs (fig. 3) in contrast to the pair of sensory antennae seen in terrestrial groups mentioned above. The relationships of the Crustacea, with two pairs of antennae, and of the Trilobita with, as far as is known, one pair of antennules and postantennulary cephalic limbs basically resembling those of the trunk, are problematical.

CLASSIFICATION

The following scheme, except in a few sections (see *Disputed Relationships* below) is generally accepted by students of the Arthropoda.

Class Crustacea (fig. 4).—Head composed of unsegmented acron fused with preoral preantennulary, antennulary and antennal somites, the last two bearing paired antennule and antenna; and postoral somites bearing paired mandible, maxilla 1 and maxilla 2; thorax comprises a series of leg-bearing segments, some of which may be fused with the head, their limbs becoming feeding organs (maxillipedes); the abdomen may or may not bear limbs, and terminates in a telson. Legs may be biramous.

Class Trilobita.—Paleozoic, body molded longitudinally into three lobes; one pair of antennules; a head shield bearing eyes is followed by movable trunk segments, the hindermost being immovably united to form a pygidium; postantennulary cephalic limbs and trunk limbs of a common type with two rami.

Chelicerata.—Anterior limbs a pair of chelate chelicerae used in feeding.

Class Merostomata.—Prosoma bearing preoral chelicerae, five pairs of postoral walking legs and chilaria or metastoma; opisthosoma of 9–12 somites bearing genital operculum and five pairs of branchiate limbs or branchiae, the terminal telson forming a spine.

Class Arachnida (fig. 3).—Prosoma with embryonic precheliceral somite, preoral chelicerae and postoral pedipalps and four pairs of walking legs; mesosoma bearing lung books or tracheae; limbless metasoma present or absent.

Monognatha.—One pair of gnathal limbs (jaws) behind the mouth.

Class Onychophora.—Besides the unsegmented acron possessed by all Arthropoda, the head comprises the preoral antennal somite and the postoral jaw and slime papilla somites, all bearing limbs; soft integument; a long series of trunk somites with short paired legs.

Dignatha.—Two pairs of gnathal limbs behind the mouth.

Class Pauropoda (fig. 4).—Minute; head comprising acron and preantennal, antennal and premandibular somites in front of the mouth, only the antennal somite carries limbs (antennae) and postoral mandibular and maxillary somites with their limbs; trunk with 9 or 10 limb-bearing somites; a reduction in every other tergite providing stability for the type of gaits employed.

Class Diplopoda.—Head, as far as is known, is as in the Pauropoda, with postoral mandibles and gnathochilarium; typically specialized herbivores burrowing by the motive force of their legs, large numbers (up to some 130 pairs) of which are obtained by the formation of diplosegments along most of the trunk, each bearing two pairs of legs.

Trignatha.—Three pairs of gnathal limbs behind the mouth.

Class Chilopoda.—Preoral head much as in Pauropoda, bearing antennae; postoral mandibles, maxilla 1 and maxilla 2; first trunk segment bears poison claws; followed by a variable number (15–177) of trunk somites bearing paired walking limbs.

Class Symphyla (fig. 3).—Preoral head much as in Pauropoda, bearing antenna; postoral mandible, maxilla 1 and maxilla 2; trunk composed of 14 somites the anterior 12 bearing running legs. A duplication of tergites on segments 4, 6 and 8 enhances body flexibility.

Class Collembola.—Head segmentation much as in Symphyla, bering antenna, but postoral entognathous mandible and maxilla 1; maxilla 2 present; trunk with nine somites, the first three bearing thoracic legs; typically the abdomen bears hamula and furcula used in jumping.

Class Insecta.—Head segmentation, antenna and mouth-parts much as in Symphyla but with important differences in detail; trunk of 14 somites, the first 3 bearing thoracic legs and 2 pairs of wings.

Disputed Relationships.—The Apterygota, lacking wings (the Thysanura and the entognathous Diplura, and Protura) are usually regarded as outside the main line of descent of the winged insects, the Diplura and Protura showing resemblances to the Collembola. Whether the Pycnogonida represent a separate class, or a section of the Arachnida, is uncertain. The minute Tardigrada are usually regarded as aberrant arthropods. Although some authorities consider the horseshoe crabs as a subclass (Xiphosura) of Merostomata, others regard them as a separate class. The Collembola is sometimes given ordinal rank under the class Insecta.

ARTHUR, a legendary British king, the sovereign of the knights of the Round Table (*q.v.*) in a famous cycle of medieval romances. Whether the legends concerning Arthur had a historical basis and how and where (in Wales or in those parts of northern Britain inhabited by Brythonic—Welsh-speaking—Celts) these legends originated, scholars are not agreed. In the *Historia Britonum* of Nennius, a 9th-century compilation, a section describes Arthur's 12 battles against the Saxons, culminating in the victory of Mt. Badon. The *Annales Cambriae* (*c.* 950–1000) record the battle of Camlann (537), "in which Arthur and Medraut fell," and also Arthur's victory at Badon (516). Badon is mentioned in Gildas' *De excidio et conquestu Britanniae* (*c.* 547) as having occurred in the year of Gildas' birth (*c.* 500) but here the battle is not connected with Arthur. The assumption that there was a historical Arthur who led the Welsh resistance to the West Saxon advance from the middle Thames rests on an unwarranted conflation of Gildas, Nennius and the *Annales Cambriae*. R. G. Collingwood's picturesque variant of this view is speculative: according to his *Roman Britain and the English Settlements* (1936) Arthur, described by Nennius as *dux bellorum*, was a professional soldier, serving the British kings, who had a cavalry force trained on Roman lines which he switched from place to place to meet the Saxon threat.

It is difficult to assess the historical value of these early chronicles: Nennius, for example, is a compilation and the "Arthuriana" section is from an undetermined source, possibly a poetic text. The long Welsh poem *Y Gododdin* (*Book of Aneirin*, original version *c.* 600) alludes to Arthur as a great warrior but it is not known when this allusion entered the text.

If Nennius is comparatively sober, the references to Arthur in early Welsh literature (*q.v.*) make him into a king of wonders and marvels. He is sometimes referred to in 13th-century manuscripts in terms appropriate to heroic poetry—as the *guledig* ("ruler"—*Book of Taliesin* xv) and the *ameraudur* ("emperor"—*Black Book of Carmarthen* xxii)—but elsewhere appears surrounded by a mythological aura. In the strange and allusive poem "Preiddeu Annwfn" (*Taliesin* xxx) he undertakes a disastrous expedition against certain miraculous fortresses, which some scholars have located in the underworld. He also slays strange monsters (*Black Book* xxi) and hunts the boar Trwyth (*Mirabilia* and the 12th-century prose romance *Culhwch and Olwen*). He is associated with other heroes—no doubt originally independent—and this conception of a heroic band of which Arthur is chief led to the idea of Arthur's court (*Culhwch and Olwen*). Arthur, Bedwyr (Bedivere), and Cai (Kay) seem early to have formed a group. The *Mirabilia*, a late addition to Nennius (*c.* 1000), connects the hunting of Trwyth, as well as Arthur's dog Cabal and Arthur's son Amr, with the topography of south Wales. In *Culhwch and Olwen*, Arthur's role is somewhat passive (according to Sir Ifor Williams, his sole personal exploit was the efficient slaughter of one old woman), the work being essentially a love story based on a whole mass of romanticized folk material centred on the young hero and heroine rather than on Arthur who assists them. This conception of Arthur's role is very similar to that in the later French romances of Chrétien de Troyes (*q.v.*).

From the beginning of the 12th century, Arthurian stories were in circulation in France and other countries in the French cultural sphere. The existence of such tales is vouched for by William of Malmesbury and, more doubtfully, by Wace (*q.v.*). Little is known about the way they reached the French-speaking world. The notion that Arthur (like Charlemagne and Frederick Barbarossa) had never died was at this time widely current, to judge from such evidence as that provided by Herman de Tournai (*c.* 1140), a line in the "Stanzas of the Graves" (*Black Book* xix) which has been taken as denying that Arthur has a grave, and the strongly classicized story of Arthur's departure to Avalon (*q.v.*) in Geoffrey of Monmouth's *Historia regum Britanniae* (*c.* 1135). There is probably genuine Celtic tradition behind the story of the abduction of Guinevere by Melwas in Caradoc of Llancarfan's *Vita Gildae*. Stories such as those of Arthur and his warriors sleeping in Mt. Etna or of Arthur leading the wild hunt are probably just examples of the association of a well-known name with common folklore themes. Similarly, the representation of Arthur riding a goat in an Otranto mosaic may be just a fanciful caricature.

The appearance of the *Historia* of Geoffrey of Monmouth (*q.v.*), which asserts that Caerleon (*q.v.*), sometimes identified with Camelot, was the place of Arthur's coronation, marks a decisive stage in the development of Arthur's literary fortunes: the Arthurian legend, as the middle ages knew it, is essentially the creation of this one book.

See Arthurian Legend.

ARTHUR I (1187–1203), duke of Brittany, famous in history and literature as the nephew and victim of King John (*q.v.*), was born at Nantes on March 29, 1187, the posthumous son of Geoffrey, son of Henry II of England, and of Constance, heiress of Brittany. Richard I (*q.v.*) of England recognized Arthur as his heir presumptive in Oct. 1190, and in March 1191 the king of France, Philip II, agreed that Arthur should do homage to Richard as duke of Normandy. Richard's crusade and subsequent captivity prevented him from arranging effectively for Arthur's future, but in April 1196 he demanded custody of the young duke. The Bretons refused and delivered him instead to Philip, who brought him up in his own household. Richard therefore designated his brother John as his heir, and after Richard's unexpected death on April 6, 1199, John was accepted as ruler by most of the prelates and barons of England and Normandy. But Arthur's claim to Brittany and Anjou was recognized by Philip, although a year later the treaty of Le Goulet (May 1200) arranged that he should do homage to John for Brittany. After John was condemned to forfeiture (1202) by the court of the king of France, Arthur's further claims to Aquitaine and Maine were provisionally recognized by Philip, who had already betrothed him to his daughter Mary.

In the ensuing warfare Arthur was captured by John on Aug. 1, 1202, at Mirabeau, and was imprisoned first at Falaise and then at Rouen. Although his precise fate is uncertain, there can be no doubt that he was dead before 1204 and there is a tradition that he was murdered about April 3, 1203, at Rouen or at Cherbourg, either by John himself or at his command.

ARTHUR III (1393–1458), duke of Brittany from 1457 to 1458 but known for most of his life as earl of Richmond (in French, comte de Richemont) or as the constable de Richemont (when he was constable of France), was the third son of John IV, duke of Brittany, and Joan of Navarre (afterward wife of Henry IV of England). His brother, John V of Brittany, gave him his

English title earl of Richmond in 1399. From 1410 to 1414 he served on the side of the Armagnacs in the French civil wars and became the intimate friend of Charles VI's son, the dauphin Louis. Wounded and captured in the battle of Agincourt (1415), he was a prisoner in England till 1420. Released on parole, he supported the English policy for several years, persuading John V of Brittany to sign the treaty of Troyes and being rewarded by Henry V of England with the countship of Ivry.

In 1423 Richmond married Margaret of Burgundy, widow of the dauphin Louis, and thus became brother-in-law (1) of Philip the Good, duke of Burgundy; (2) of the English regent in France, the duke of Bedford; and (3) of Charles duc de Bourbon. Offended by Bedford's refusal to give him a high command, he broke with the English and, in March 1425, was made constable of France by Charles VII.

Richmond now threw himself with ardour into the French cause and persuaded his brother, John of Brittany, to conclude the treaty of Saumur (Oct. 7, 1425) with Charles VII. In battle, however, he was several times defeated; and at court, where his rough and overbearing manners made him disliked, his influence was overshadowed by that of incompetent favourites, especially Georges de la Trémoïlle. The peace concluded between the duke of Brittany and the English (Sept. 1427) led to Richmond's expulsion from the French court. Joining Joan of Arc at Orléans in June 1429, he fought victoriously under her banner in several battles (for example, at Patay). After La Trémoïlle's disgrace, thanks to the king's mother-in-law Yolande of Aragon and to the queen Mary of Anjou (1433), Richmond was allowed to return to court. On Sept. 20, 1435, mainly as a result of his diplomacy, the treaty of Arras was signed between Charles VII and the duke of Burgundy. This turned the course of the Hundred Years' War in France's favour.

In April 1436, Richmond took Paris from the English; but it was not till May 1444 that the armistice of Tours gave him leisure to participate in the reorganization of the army. This reform had its effect in the struggles that followed. In alliance with his nephew, Peter II of Brittany, Richmond reconquered during Sept. and Oct. 1449 nearly all the Cotentin. It was moreover his rapid intervention, with 800 Breton knights, that won the battle of Formigny for the French (April 15, 1450). On Peter II's death (Sept. 22, 1457), he became duke of Brittany. He reigned little more than a year and died on Dec. 26, 1458. He left no legitimate children, though he was remarried twice: first to Jeanne, daughter of Charles d'Albret; then to Catherine, daughter of Pierre de Luxembourg, comte de Saint-Pol.

Bibliography.—The main source for the life of Arthur III is the *Chronique d'Arthur de Richemont*, by his servant and companion Guillaume Gruel (first published 1622; ed. by Achille le Vavasseur, 1890). *See* also E. ARTHUR, CHESTER ALAN (1830–1886), 21st president of the United States, was born in Fairfield, Vt., on Oct. 5, 1830. His father, William Arthur (1797–1875), when 18 years of age, emigrated from County Antrim, Ire., and, after teaching in various places in Vermont and lower Canada, became a Baptist minister. William Arthur had married Malvina Stone, an American girl who lived in Canada at the time of the marriage, and the numerous changes of the family residence afforded a basis for allegations in 1880 that the son Chester was born not in Vermont but in Canada, and was therefore ineligible for the presidency. Chester entered Union college, Schenectady, N.Y., as a sophomore and graduated with honour in 1848. He then became a schoolmaster, at the same time studying law. In 1853 he entered a law office in New York city and in the following year was admitted to the bar. His reputation as a lawyer began with his connection with the famous "Lemmon slave case" in which, as one of the special counsel for the state, he secured a decision from the highest state courts that slaves brought into New York while in transit between two slave states were *ipso facto* free. In another noted case, in 1855, he obtained a decision that Negroes were entitled to the same accommodations as whites on the street railways of New York city.

In 1859 he was married to Ellen Lewis Herndon (1837–80), daughter of a Virginia naval officer and explorer of the Amazon.

A Whig and abolitionist family background prepared him for entry into the new Republican party and he attended the Anti-Nebraska convention at Saratoga, Aug. 16, 1854. He participated in local politics in New York city and joined the state militia. When the American Civil War began he held a political appointment as engineer-in-chief on Gov. Edwin D. Morgan's staff. Soon he became successively assistant quartermaster general, inspector general, and quartermaster general of the state troops. He displayed exceptional administrative ability under trying circumstances and retired with Governor Morgan on Jan. 1, 1863. He resumed the practice of his profession, specializing in war damage claims, but continued his activities in local politics.

In Nov. 1871, he was appointed by President Grant collector of customs for the port of New York. The customhouse had long been conspicuous for the most flagrant abuses of the spoils system but Arthur, although an important figure in Sen. Roscoe Conkling's machine, combined experimental civil service examinations with patronage considerations in making appointments and made few removals for political reasons. His management did not satisfy the reform convictions of President Hayes, and a nonpartisan commission appointed by Secretary of the Treasury John Sherman recommended sweeping changes. The president asked for the resignation of Arthur and his two principal subordinates, Alonzo B. Cornell and George H. Sharpe. Arthur refused to retire under fire and his cause was espoused by Senator Conkling, for a time successfully; but on July 11, 1878, during a recess of the senate, the collector was removed, and in Jan. 1879, after another severe struggle, the senate approved. Arthur's business conduct of the office was not impugned, but he was regarded as too involved in machine politics to carry out a reform program. However, in defense of his management he insisted that he had already instituted every reform authorized by the treasury and that the recommendations of the investigating commission largely repeated his own previous proposals for improving the system.

In 1880 he was a delegate-at-large to the Republican national convention. In common with the rest of the "Stalwarts" under Conkling's leadership, he worked hard for the nomination of U. S. Grant for a third term. Upon the triumph of James A. Garfield, the necessity of conciliating the defeated faction led to the offer to the New York delegation of second place on the ticket. When Levi P. Morton declined, Arthur was offered the nomination and accepted the honour over Conkling's angry protests. His nomination was coldly received by the public; and when, after his election and accession, he actively engaged on behalf of Conkling in the great conflict with Garfield over the New York patronage, the impression was widespread that he was unworthy of his position. Upon the death of President Garfield, Sept. 19, 1881, Arthur took the oath as his successor. Coming at a period of intense factional controversy and following the assassination of Garfield, which had profoundly shocked the public mind, the accession of Arthur to the presidency created apprehensions. The widespread expressions of dismay in the press at the probable outcome of an administration in the hands of so confirmed a factionist and spoilsman as he was reputed to be are said to have deeply wounded Arthur. But his accession address was clear, judicious and reassuring, and his expressed purpose, from which he never measurably deviated, to administer his office in a spirit devoid of factional animosity, established the confidence of the nation and won for him the approval

BY COURTESY OF THE LIBRARY OF CONGRESS

ARTHUR, PHOTOGRAPHED IN 1882

of many of his severest critics. Contrary to the general expectation, his appointments as a rule were unexceptionable, and he earnestly supported the Pendleton law, passed in 1883, for the reform of the civil service. His use of the veto in 1882 in the cases of a Chinese immigration bill (prohibiting immigration of the Chinese for 20 years in contravention of the treaty of 1880) and a river and harbour bill (appropriating over $18,000,000, some of which was to be expended on insignificant streams), confirmed the favourable impression that had been made.

Other important events of his administration were the passage of the high protective tariff act of 1883—which disregarded both the report of a tariff commission and his own recommendations—the enactment of the Edmunds law prohibiting polygamy in the territories, and the completion of three great continental railroads.

Arthur was much concerned about national defense and secured increased appropriations for the navy, including funds for the construction of the first steel cruisers. One of his last official acts was the appointment of U. S. Grant as general, a special bill creating this rank having been passed in 1885. In 1884 he permitted his name to be presented for renomination at the Republican national convention but he was defeated by James G. Blaine on the 4th ballot. Although a close friend of Conkling, long an implacable political enemy of Blaine, he supported the latter in the ensuing presidential campaign. At the end of his term he returned to New York city, where he died on Nov. 18, 1886.

In appearance Arthur was an imposing figure, tall, handsome, always immaculately dressed, dignified but sociable and gracious to everyone. A widower, he depended upon his sister, Mrs. John McElroy, to act as his hostess in the White House.

See George F. Howe, *Chester A. Arthur* (1934); Herbert J. Clancy, *The Presidential Election of 1880* (1958). (E. H. Ro.)

ARTHUR, JOSEPH CHARLES (1850–1942), U.S. botanist who discovered basic facts about the life history of rusts (parasitic fungi) during research on plant diseases. He was born at Lowville, N.Y., on Jan. 11, 1850, graduated at Iowa State college, Ames, in 1872 and received the degree of doctor of science at Cornell university, Ithaca, N.Y., in 1886. In 1887 he was made professor of botany in Purdue university, Lafayette, Ind., where he served until 1915. During his professorship at Purdue he was also professor of vegetable physiology and pathology in the Indiana agricultural experiment station, and it was during this period that he made his chief contributions regarding the life history of rusts. From 1882 to 1900 he was an editor of the *Botanical Gazette*. Arthur wrote numerous botanical articles and published a *Handbook of Plant Dissection*, with Charles R. Barnes and John M. Coulter (1886), *Living Plants and Their Properties*, with Daniel T. MacDougal (1898), and *Manual of the Rusts in United States and Canada* (1934). He died April 30, 1942.

ARTHURIAN LEGEND, the body of stories concerning King Arthur (*q.v.*), themes and incidents from which were variously treated by medieval writers in most western European languages. They describe the birth of Arthur, the establishment of the knightly fellowship of the Round Table (*q.v.*), his own exploits and those of his knights, and finally relate how the adultery of Lancelot and Guinevere and the quest for the Grail (*q.v.*) led to the destruction of that fellowship and Arthur's kingdom and to the death of Arthur himself.

The Legendary History of Britain.—Although stories about King Arthur and his court were extremely popular in Wales before the 11th century, the Arthurian legend as known today is almost wholly the creation of the French middle ages. Arthur first achieved European fame through the *Historia regum Britanniae* (*c.* 1135) of Geoffrey of Monmouth (*q.v.*), a reckless forger who created, partly from Celtic tradition but still more from classical and biblical reminiscences, the fictional history of a Britain which had received undying lustre from the glorious rule of Arthur. The basic conception of a great warrior who triumphantly defeats the Saxons is taken from Nennius' *Historia Britonum* (*c.* 800): but Geoffrey's Arthur, not content with repelling the Saxons, subjects Scotland, Norway and France to his rule and, after refusing to pay tribute to Rome, defeats a Roman army in eastern France. At this moment of his highest glory he is summoned home to put down a rebellion led by his nephew Mordred (Modred), who has been left in Britain as regent and has seized Arthur's crown and wife. In a last battle on the river Camel, Mordred is defeated but Arthur, mortally wounded, disappears to Avalon (*q.v.*).

Some features of this story are obviously complete fabrications when applied to Arthur; for example, the account of how Uther Pendragon, aided by Merlin, took the shape of Gorlois, duke of Cornwall, and in this shape begot Arthur on Igerne (Igraine), Gorlois' wife, is a blatant adaptation of the classical story of Zeus and the wife of Amphitryon. Even apparently genuine Celtic features (*e.g.*, the sword Excalibur and the journey to Avalon) are given a strong classical colouring, while Kay and Bedivere, Arthur's closest companions in the Celtic tradition, are transformed into feudal barons. The theme of Arthur the world-conqueror is obviously patterned upon the exploits of such worthies as Charlemagne and Alexander the Great, while Arthur's disastrous fall at the height of his prosperity conforms to the accepted medieval idea of tragedy. Wace's *Roman de Brut* (1155), an Anglo-Norman adaptation of Geoffrey, and Layamon's much expanded early Middle English version of Wace, the *Brut* (*c.* 1200), both contain material lacking in Geoffrey, especially in connection with the Round Table and Avalon. (*See* also WACE and LAYAMON).

The Medieval Romances.—Five romances (*c.* 1160–80) by Chrétien de Troyes (*q.v.*) make Arthur the somewhat passive ruler of a realm of marvels, although he is permitted to retain the imperial status given him by Geoffrey. But Chrétien's works are basically adventure romances with a strong love interest, in which a high-born young knight and his lady-love play the leading roles. The obvious Celtic analogue is *Culhwch and Olwen*. Very little is known about Chrétien's presumed Celtic sources, although his *Lancelot* (*Le Chevalier de la charette*) has analogies with the story of the abduction of Guinevere by Melwas in the *Vita Gildae*. Chrétien's *Le Conte del Graal* (*c.* 1180) introduces the theme of the Grail into the Arthurian story; the origin of the Grail—it is the dish of the Last Supper given by Christ to Joseph of Arimathea—and its early history was related in Robert de Borron's non-Arthurian romance *Joseph d'Arimathie* (*c.* 1200?).

Glastonbury became connected with both the Grail legend and the story of Arthur, and the monks began to exploit its fame from the mid-12th century on: in 1191 a fraudulent exhumation of Arthur's remains took place there.

The Arthurian prose romances of the 13th century are built round two main themes: the winning of the Grail and the love story of Lancelot and Guinevere. Robert de Borron in his *Merlin* (*post* 1200) had established links between the Round Table, Merlin and the Grail hero Perceval (Parsifal). There seems to have existed an early prose romance of Lancelot which related Lancelot's successful wooing of Guinevere, Arthur's wife, and his friendship with Galehaut, the high prince. This romance formed the kernel of a cyclic work which is now known either as the prose *Lancelot* or the "Vulgate cycle" (*c.* 1225). The Vulgate cycle connected the theme of Lancelot and Guinevere with the Grail legend through the figure of Galahad, Lancelot's son by Elaine, daughter of Pelles the Grail warden. In the branch of the Vulgate cycle known as the *Queste del Saint Graal*, an austerely religious work reflecting the mystical teaching of Bernard of Clairvaux, Galahad achieves the vision of God through the Grail as fully as is possible in this life, whereas Lancelot, stained by his adultery with Guinevere, is shown as a novice whose progress along the Mystic Way requires a life of penitential discipline. The Lancelot story was prefaced by a branch of the cycle based on Robert de Borron's *Merlin*, a verse romance which had recounted Arthur's begetting (as in Geoffrey), his fostering by Antor, father of Kay, and his winning of the crown by drawing a magic sword from a stone. The writer of the Vulgate cycle turned this work into prose and extended it by a long and wearisome pseudohistorical narrative dealing with Arthur's wars against the Saxons. A final branch, the *Mort Artu*, contained an account of Arthur's Roman campaign and war with Mordred (based on Geoffrey), to which was prefixed the story of Lancelot's renewed

adultery with Guinevere and the disastrous war between Lancelot and Gawain which ensued. (*See* also articles on GAWAIN; GUINEVERE; LANCELOT; MERLIN; and PERCEVAL.)

A later prose romance (*c.* 1240), formerly known as "the pseudo-Borron" but described as the "post-Vulgate" romance by modern scholars, combines the story of Arthur with material from the prose romance of Tristan, and completely discards the pseudo-historical approach in favour of a thoroughly romantic treatment which develops such themes as the incestuous birth of Mordred through the commerce between Arthur and his sister; the appearance of Excalibur out of a lake (to match its disappearance into the lake at the end of the *Mort Artu*); the striking of the Dolorous Stroke (the slaying of King Pellean with the Holy Grail lance) by the unfortunate knight Balin, who thus inaugurates the marvels and enchantments of Britain which can only be ended by the pure knight Galahad; the fight in which the twin brothers Balin and Balan kill each other; and the final destruction of the Arthurian kingdom by King Mark of Cornwall.

The Survival of Arthurian Legend.—The legend, as it appears in the Vulgate cycle and the post-Vulgate romance, was transmitted to the later English-speaking world by Sir Thomas Malory (*q.v.*). In the 15th century, English chroniclers showed a renewed interest in Geoffrey's *Historia* and in Tudor times—*e.g.*, in Michael Drayton's *Polyolbion* and Edmund Spenser's *Faerie Queene*—the fictitious kings of Britain became more or less incorporated into the official national mythology. Thanks to the chroniclers and Malory, the legend remained alive in England in the 17th century although it had by then lost its interest for continental readers. Milton meditated an epic on Arthur. Cherished mainly by antiquaries during the 18th century, it again became popular in the Victorian era, favoured as it was by medievalizing tendencies in art and religion, and enjoyed a dubious second flowering in the works of Tennyson, Swinburne, William Morris and others. In the 20th century writers continued to draw on the legend: the American poet Edwin Arlington Robinson wrote an Arthurian trilogy in verse, and in England T. H. White retold the stories freshly and skilfully in a fine series of novels collected as *The Once and Future King* (1958). Charles Williams wrote a considerable body of verse on Arthurian themes, notably in *Taliessin Through Logres* (1938) and *Arthurian Torso*, ed. by C. S. Lewis (1948).

(F. WH.)

ARTICHOKE. The globe, common, green, Italian, French or Paris artichoke (*Cynara scolymus*) is sometimes also called the true artichoke to distinguish it from the Jerusalem artichoke (*Helianthus tuberosus*), a quite different plant. Both plants belong to the family Compositae (*q.v.*).

Globe Artichoke.—The globe artichoke is a large, coarse, herbaceous, thistlelike, perennial plant. The edible parts are the fleshy bases of the immature flower heads, together with the fleshy bases of the large bracts attached. The aboveground parts die down each year after flowers are formed. New shoots arise the next season from buds of the underground crown atop the perennial rootstock. These shoots produce rosettes of deeply cut, pinnatifid, woolly leaves two to three feet long; later, sturdy, branched flower stalks rise three to five feet. The fully developed heads of purplish flowers are six inches or more across. After four to eight years the cluster of rosettes from a crown becomes very crowded, reducing the size and quality of heads formed. The plant then is renewed by planting divisions of the crown or rooted offshoots that arise from it. Seeds are produced by mature flower heads, but the plants are propagated vegetatively because the seedlings do not come true to variety.

The artichoke is native to lands about the middle and western Mediterranean, whence it was carried to the eastern Mediterranean region about 2,000 to 2,500 years ago. In ancient and medieval times the young or blanched leaves rather than the flower heads were eaten. The modern, edible-flowered form was first recorded in Italy about 1400. From there it was taken to France and England. It was introduced to Louisiana by the French and to California by the Spanish in colonial times. It is popular and extensively grown in France, Belgium and the Mediterranean countries. In Europe from the 17th to 20th centuries the leaves of artichoke were believed to have some specific medicinal properties. The plant has no recognized value in medicine in America.

Globe artichoke requires a rich soil and a mild, humid climate. It is grown in the United States on a large scale only in the mid-coastal counties of California near the ocean. About 8,000 to 10,000 ac. are harvested annually; yields average about two tons per acre.

Jerusalem Artichoke.—The Jerusalem artichoke is a tuber-bearing type of sunflower, native to North America. A wide range of wild forms can be found in the United States. The aboveground part of the plant is a coarse, usually much-branched, frost-tender annual, six to ten feet tall. The numerous showy flower heads appear in late summer or early autumn, have yellow ray flowers and yellow, brownish or purplish disk flowers. The underground tubers vary from oblong to much elongated, regular to rough and branched, and from very small up to three to four ounces. Skin colours range from light buff through yellowish to brown, red and purple. The tubers are very thin-skinned and soon shrivel on exposure to dry air; the flesh is white and crisp. The plant is propagated by planting the tubers.

Samuel de Champlain reported seeing the Jerusalem artichoke about 1605 in the gardens of the Indians on Cape Cod. The plant was first described by Colonna in Italy in 1616. It was introduced into England in 1616 or 1617, probably into France about the same time, and was grown in northern Germany in 1632. It has long been cultivated extensively in France as a stock feed and has attracted some attention as a potential crop plant in northern Europe. In America it is rarely cultivated, but small quantities are used in making pickles, relishes and dietary preparations.

The tops and tubers of Jerusalem artichoke contain no starch. The carbohydrates of the tuber occur mainly as inulides, along with 1% to 3% of free sugar. There is no good evidence that man or animals derive food value from these inulides.

The flavour of the tubers suggested to Champlain, and to others later, the flavour of the artichoke, and the name Jerusalem artichoke was first recorded in 1622. The origin of "Jerusalem" in the name is not definitely known. (V. R. B.)

ARTICLES OF CONFEDERATION. The Articles of Confederation, the first constitution of the United States, were written in 1776–77, ratified March 1, 1781, and served until they were replaced by the constitution of 1787 on March 4, 1789.

The leaders of the American Revolution were thoroughly familiar with a central government: that of Great Britain. They were familiar too with the idea of a central government in America, since many plans for one had been proposed during the 18th century. Most of the plans had been for frontier defense and none had been adopted, so they offered little guidance in 1776.

When Americans declared their independence they agreed that the new nation must have a common government, but they disagreed then, as they continued to disagree for generations, about the kind of government it should be and, above all, about the amount of power it should have. One group of leaders in 1776 wanted a strong central government with the power to regulate trade, control finance, dispose of western lands, check state legislative majorities and intervene within the states to maintain order. They wanted what came to be called a "national" government, but in 1776 such leaders were a minority. They were opposed by most of the men who had been the aggressive revolutionary leaders, men who had denied the authority of parliament over the colonies and

who had insisted that each colonial legislature was supreme within its own domain. Equally important in their political thought was their distrust of powerful government and of men in political office. They believed that when men gained political power they inevitably tried to gain even more power and that in so doing they often corrupted government and subverted the liberties of the people. Therefore, when the revolutionary leaders wrote the state constitutions, they limited the power of officeholders and protected the people from government by bills of rights.

When men who held such beliefs took up the formation of a constitution for the United States, they rejected a document proposed by the "nationalists." The constitution finally adopted by the continental congress in 1777 and sent to the states for ratification provided for a strictly "federal" government, which had no authority over the states or their citizens. The Articles of Confederation declared specifically that "each state retains its sovereignty, freedom, and independence" and all powers and rights not "expressly delegated to the United States, in Congress assembled." Members of the continental congress were elected annually by the state legislatures and subject to recall at any time. Distrust of power seekers was expressed in the provision that no man could be a member of congress for more than three years in any six. Congress was denied the power of taxation, a logical reflection of the long fight against the taxing power of the British parliament. Nor did congress have the power to regulate trade, although it was given the exclusive power of making commercial treaties.

Opposition to granting the taxing power to congress was so overwhelming that it was not debated, but lesser issues, which continued to be issues in later constitutional history, were debated fully. One was the question of representation. The states with large populations insisted that they should have more votes in congress than the small states. The latter, and those leaders fearful of a powerful central government, insisted on the equality of the states and established the rule that each should have one vote. A second issue was the apportionment of common expenses. The northern states, assuming their lands to be of high value, argued that population was the best index of wealth and ability to pay. The southern states, with poorer land and large populations, established the principle that expenses should be apportioned according to the value of improved lands. The most important conflict concerned western lands. Five states had definite western boundaries, and they insisted that congress should have control. The other states, some with claims extending to the Pacific ocean, inserted a provision in the articles prohibiting congress from interfering with the lands of the states. Maryland, a "landless" state, backed by speculators with interests in the region claimed by Virginia, refused to ratify the articles. Finally, Virginia ceded the Old Northwest to congress, requiring it to nullify speculators' claims, and Maryland was forced to ratify on March 1, 1781.

Despite the evident distrust of centralized power embodied in the Articles of Confederation, they both limited the independence of the states and granted significant authority to congress. The citizens of each state were guaranteed the privileges of the citizens of any state to which they moved. Provision was made for the extradition of criminals fleeing from one state to another. A court of arbitration, under the supervision of congress, was provided for the settlement of disputes among states. The freedom of the states was limited by the powers granted to congress. It had the sole power of making peace and war and appointments of officers, except regimental officers, of troops in the service of the United States. It had sole control of diplomatic negotiations. It could borrow money, issue paper money and fix the value of money coined by it and the states. It had the sole authority to fix weights and measures, establish and manage a post office and manage affairs with Indians not a part of any state.

Despite the lack of coercive authority over the states and their citizens, the Articles of Confederation had many of the important provisions later incorporated in the constitution of 1787. *See* also UNITED STATES (OF AMERICA): *History.*

ARTIFICIAL LIMBS: *see* PROSTHETICS.

ARTIFICIAL ORGANS are machines designed to replace the functions of organs of the body for varying periods of time, usually during surgery. The artificial kidney, heart-lung machines, and mechanical hearts, the subjects of this article, are the leading examples of artificial organs. (For artificial limbs *see* PROSTHETICS.)

Artificial Kidney.—This apparatus removes, by dialysis (*q.v.*), noxious metabolic substances from the blood. These substances accumulate because of faulty kidney function and can be lethal if they continue to increase. In using the artificial kidney, blood from an artery is led through sterile coils of tubing (made from a semipermeable membrane such as cellophane) lying in a suitable salt solution bath. The blood is prevented from clotting in this altered environment by adding heparin (*see* THROMBOSIS AND EMBOLISM: *Anticoagulant Therapy*). The harmful products of uremia (insufficient kidney function) move out of the blood, where they are in higher concentration, pass through the cellophane wall, and collect in the surrounding fluid. When the blood has traversed this circuit it returns to the patient, purified by dialysis during its passage.

"Vividiffusion," or an artificial kidney, was first described by John J. Abel, L. G. Rowntree, and B. B. Turner in 1913. Unsolved technical problems limited the effectiveness of the machine, however. The first successful clinical instrument, developed by W. J. Kolff (1944), consisted of long lengths of tubing wound horizontally on a slotted wooden drum. Blood from the patient flowed through these casings, which then dipped into a reservoir filled with an appropriate exchange solution as the cylinder rotated.

Other dialyzing units subsequently developed included vertical windings of dialyzing tubing on a cylinder (Nils Alwall, 1947) and multiple cellophane "sandwiches" overlaid with impermeable plastic or rubber sheets (Leonard T. Skeggs and Jack R. Leonard, 1948). Variations on these concepts have been built into other types of artificial kidneys that are widely available. Although they can serve only as a temporary and incomplete replacement for normal renal function, artificial kidneys have permitted reversibly damaged kidneys to recover. (For the surgical transplantation of kidneys *see* TRANSPLANTS, TISSUE AND ORGAN.)

Heart-Lung Machines.—These consist of an artificial lung (oxygenator) and a substitute heart (pump). For nearly a century beginning about 1868, scientists attempted to develop a mechanical unit capable of (1) restoring oxygen to blood depleted of this element in its movement through the tissues, and (2) removing the excessive carbon dioxide that accumulates during this same passage. Many of the same investigators worked also on the development of a pump to supplant heart action temporarily (*see* below). Decades of animal investigation culminated in the first successful application of an artificial heart-lung machine to an operation on man, by John H. Gibbon, Jr., on May 6, 1953. Within a brief time other scientists, working independently, revealed heart-lung machines they had developed. In the 1960s the Gibbon type (stationary screen), DeWall-Lillehei (bubble oxygenator with a collecting helix), Björk-Kay-Cross (rotating solid, fluted, or straight disk), Dennis (rotating screen disk), and other devices improvised from the principles embodied by these types were in use in dozens of surgical centres throughout the world.

For intervals of an hour or more any one of the proven types of heart-lung machines can accept the entire venous return of a large (100 kg. [220 lb.]) patient. In such a case the blood is pumped back into the patient's arteries in a volume sufficient to maintain life at even the most distant parts of the patient's body as well as in those centres with the greatest requirements (brain and nervous tissue, liver, adrenals, kidneys). To do this, up to 5,000 ml. (about 1⅓ gal.) or more of blood must be moved each minute. While the heart is relieved of its pumping duties it can be stopped by drugs or cooling and then started by warming or electrical means. Meanwhile the surgeon can open this organ and repair or replace valves or close abnormal holes inside.

Prolonged dependence on these units as replacements for the lung and heart was not practical in the 1960s. Equipment was

too bulky; also, the lining surfaces of the oxygenator and all tubing were less compatible than the blood vessels of the patient. Therefore, while the machines were being used, blood had to be made incoagulable by the use of heparin (which can be reversed at will with other drugs) to prevent the development of clots that might break loose and either plug the unit or damage the patient.

By means of these machines tens of thousands of children and adults with heart defects, both congenital and acquired, have been operated on successfully with establishment of improved heart function and circulation. Once these necessary corrections have been made, for congenital lesions particularly, the patient's life expectancy is, under most circumstances, comparable to that of a person born with a normal heart.

Mechanical Hearts.—Instruments capable of replacing the pumping action of the normal heart for prolonged periods of time, without damaging excessively either the fluid or the cellular elements of whole blood, were the goal of investigative groups working in the 1960s on specific parts of the problem. On the way to this goal, several kinds of appliances were tried; they were designed to reduce, rather than take over entirely, the total work load of a heart with impaired functional capacity. In general these units consisted of either (1) counterpulsation (diastolic augmentation) equipment that pulsed the blood during the heart's "resting" phase between beats, or (2) an auxiliary ventricle that substituted temporarily by pumping a portion of the normal cardiac output. Use of these devices under experimental conditions provided certain limited benefits to the circulation, including the heart; but the benefits were achieved at the expense of creating serious new biological problems which, if allowed to continue, would have been incompatible with health. (R. L. V.)

ARTIFICIAL RESPIRATION. The timely administration of artificial respiration to persons who have stopped breathing while their hearts are still beating often decides whether these persons live or die. Artificial respiration, if applied quickly and properly, can prevent deaths from drowning, choking, strangulation, suffocation, carbon monoxide poisoning and electric shock.

In all of these events except electric shock, breathing ceases because there is not enough oxygen in the blood to enable the heart muscle and respiratory centre of the brain to function properly. When the oxygen in the blood becomes insufficient (anoxia), the heart usually continues to beat, although as a rule so feebly that there may be no noticeable pulse for about five minutes after respiration stops. This is not true, however, in electric shock, which causes momentary paralysis of the heart muscle as well as interruption of the flow of blood to the respiratory centre of the brain.

FIG. 1.—METHOD OF CLEARING AIR PASSAGE BEFORE APPLYING ARTIFICIAL RESPIRATION TO CHILDREN

Rescuer holds child in head-down position and sharply pats him on back

Resuscitation by artificial respiration consists chiefly of two actions: (1) establishing and maintaining an open air passage from the upper respiratory tract (mouth, throat and pharynx) to the lungs, and (2) exchanging air and carbon dioxide in the terminal air sacs of the lungs while the heart is still functioning. Time is an important factor in successful resuscitation not only in the urgency with which a first aid method is used but also in the continued application of a technique that may eventually revive an unconscious victim.

Two methods of artificial respiration were recommended by the American National Red Cross and the American Medical Association in the early 1960s. One method, known as expired air inflation or "mouth-to-mouth breathing," is widely accepted for use with children and infants and also can be applied to adults when other methods are not effective.

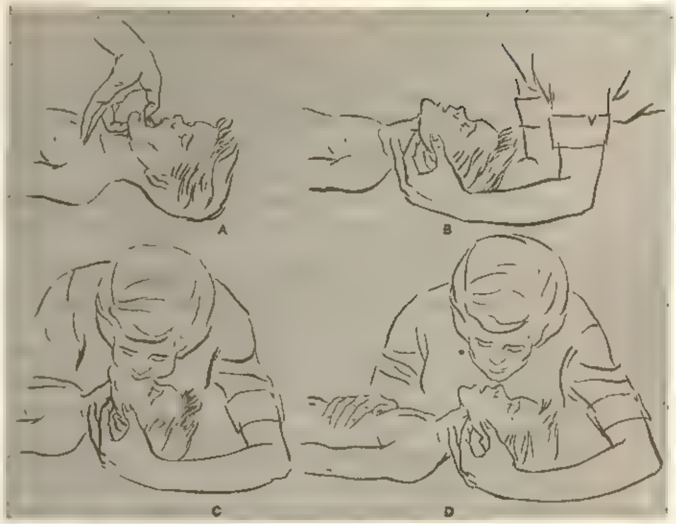

FIG. 2.—MOUTH-TO-MOUTH RESUSCITATION FOR A CHILD

(A) Rescuer opens child's air passage. (B) Rescuer holds jaw with hand under angle of child's jaw and (C) places mouth over child's mouth and nose, breathing gently to inflate the child's lungs. (D) When child's lungs expand, rescuer places gentle pressure on abdomen to assist exhalation

Mouth-to-Mouth Technique.—The first step in resuscitation, no matter what type of artificial respiration is used, is to quickly clear the mouth and throat of any foreign material or mucus that might obstruct the air passage. In the case of an infant or child hold the victim in a head-down, face-down position with the right hand and forearm (fig. 1). Pat him sharply on the back with the other hand. This should clear the upper respiratory passages.

To prepare for mouth-to-mouth breathing, place the child on his back. With the thumb and middle finger of the left hand (thumb under the tongue) lift the lower jaw forward and upward to open the air passage fully (fig. 2[A]). Hold the jaw in this position with the left hand under the angle of the jaw (fig. 2[B]). The rescuer should place his mouth over the child's mouth and nose, making a relatively leakproof seal (fig. 2[C]). Breathe into the child's mouth with positive pressure. With an infant use short puffs; larger amounts may damage his lungs. As the chest rises and the lungs expand the rescuer should place his right hand on the upper abdomen between the ribs and the navel (fig. 2[D]). With gentle pressure of the right hand the air is expelled from the lungs.

The rescuer should take a deep breath during each exhalation of the victim; the mouth-to-mouth inflation-exhalation cycle should be repeated about 15 to 20 times a minute.

With an adult the same procedure is followed except that both hands are generally needed to elevate the jaw in an upward and

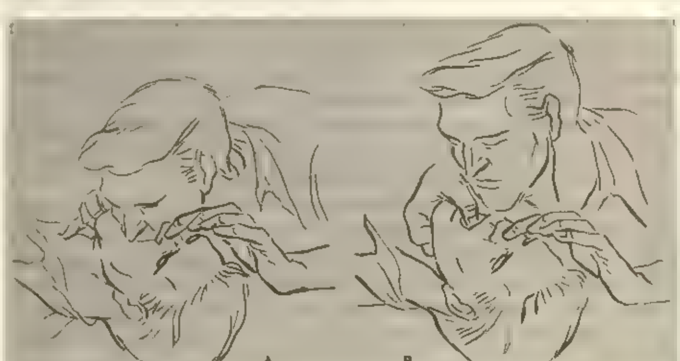

FIG. 3.—MOUTH-TO-MOUTH RESUSCITATION FOR ADULTS

(A) Rescuer elevates victim's jaw, clamps nostrils and places mouth over victim's mouth, breathing to inflate the victim's lungs; (B) rescuer allows victim to exhale before repeating forced inhalation

outward position where it can be maintained with the right hand (fig. 3). Use the fingers of the left hand to clamp the nostrils of the victim. Press the mouth firmly against the lips of the victim to make a tight seal. Inflate the lungs of the victim with forceful, short, even breaths, causing the chest to rise as the lungs are filled. Allow passive exhalation (fig. 3[B]) and then repeat the forced inflation 12 to 15 times a minute.

In both youngsters and adults, mouth-to-mouth resuscitation should be continued until normal breathing returns or the victim is pronounced dead by a physician.

In May 1958 the American Medical association published the report of the Symposium on Mouth-to-Mouth Resuscitation which stated:

"Resuscitation with expired-air breathing is simple and effective. It is readily adaptable to babies, children and adults without adjunct equipment. Rescuers can maintain mouth-to-mouth breathing for an hour or more without fatigue even when the victim is twice the size of the rescuer. Skilful performance of expired air breathing is an easily learned lifesaving procedure. It has revived many victims unresponsive to other methods and has been proved in real emergencies under field conditions."

The Holger Nielsen Method.—Another method of artificial respiration that has been widely used is the "back pressure-arm lift" method. This technique was first described in 1932 by Col. Holger Nielsen of Denmark.

The procedure is as follows: (1) Place the victim on his abdomen (fig. 4) with face turned to one side and the elbows bent so

FIG. 4.—HOLGER NIELSEN BACK PRESSURE-ARM LIFT METHOD

(A) Rescuer places hands on victim's back and, slowly rocking forward, exerts steady pressure; (B) rescuer releases pressure by rocking backward, lifting victim's arms forward and up and then down

that one cheek rests on the back of the hands. Quickly clear the victim's mouth and throat of any material that might obstruct the free flow of air. At the same time pull the tongue forward. (2) Kneel at the head of the victim while facing him; place open hands on the victim's back (fig. 4[A]) at a level just below the armpits with fingers spread and thumbs touching. (3) Rock forward slowly on extended arms while exerting steady pressure downward on the back. This forces air out of the lungs. Do not exert sudden or violent pressure. (4) Release the pressure slowly and rock backward while grasping the arms of the victim just above the elbows (fig. 4[B]); lift the arms forward and upward until you meet resistance, then slowly lower the arms to the ground. This arm-lift causes active inspiration by pulling on the chest muscles and arching the back.

The cycle of press and release-lift and release should be repeated 10 to 12 times a minute and continued until natural breathing occurs or the victim is pronounced dead.

Drowning.—In cases of near-drowning it is imperative to start artificial respiration as quickly as possible and to provide to the lungs a sufficient supply of oxygen so as to ensure the continuing function of the heart and the brain. Do not be concerned about water in the lungs or the stomach. Valuable time should not be wasted in an effort to evacuate the water or loosen the clothing.

Place the unconscious victim on his back and start mouth-to-mouth resuscitation. If the stomach bulges when inspiration is forced, exert moderate pressure over the stomach area during expiration and thereby evacuate some of the water from the stomach.

FIG. 5.—BACK PRESSURE-HIP LIFT METHOD

(A) Rescuer lifts victim's hips, rotating them in pivoting motion; (B) rescuer lowers victim's hips, placing hands on victim's back to force air out of lungs with steady pressure

See that the air passage from mouth to lungs remains open and that no regurgitated water or food is allowed to accumulate in the mouth. Do not turn the victim over in an attempt to empty the stomach.

If the lungs expand and expiration can be heard or felt, it can be assumed that the most effective method of artificial respiration is being used and no attempt should be made to change to another method. Use of the mouth-to-mouth technique should continue until the victim resumes breathing or a physician pronounces him dead. Shallow breathing by the victim should be supplemented by short mouth-to-mouth assistance that does not interfere with his natural exhalation.

If mouth-to-mouth resuscitation is not productive, some type of manual artificial respiration should be used such as the Nielsen method described above, or a modification of the Nielsen method called the "back pressure-hip lift" method in which the rescuer straddles the prone victim at the hips. While the rescuer supports himself on one knee and the opposite foot, he lifts the hips of the victim upward about 12 in. and rotates them with a pivoting motion (fig. 5[A]). Then the hips are lowered and the rescuer quickly places his outstretched hands on either side of the victim's back below and lateral to the shoulder blades (fig. 5[B]). Slow, steady pressure is exerted downward, forcing air out of the lungs.

The cycle is then repeated with a pivoting motion in the opposite direction; each cycle lasts 10 to 15 sec.

ARTIGAS, JOSÉ GERVASIO (1764–1850), father of Uruguayan independence and national hero, was born June 19, 1764, probably in Montevideo; his ancestry was Spanish. As a youth he was a rural gaucho or cowboy. In 1797 he entered the Spanish military forces, then mainly engaged in exterminating bandits. In 1810 Artigas offered his services to the Buenos Aires patriot junta leading the independence movement against Spain. After a brilliant victory at Las Piedras, he laid siege to Montevideo, held by Spanish forces, but a Spanish request for Portuguese help from Brazil and the patriots' defeat at Guaqui led to the lifting of the siege. In the face of superior Portuguese forces, Artigas led a dramatic mass exodus, involving some 16,000 persons or about one-fourth of the population of Uruguay, to Argentine territory.

Artigas became the champion of federalism against Buenos Aires' efforts to assert centralized control over the whole Río de la Plata region. A confused period of civil war resulted in 1814. In the next two years Artigas was at the zenith of his power, ruling over approximately 350,000 sq.mi. of what is today central Argentina and Uruguay. His emphasis on decentralization proved

his undoing, however. A later Portuguese invasion ultimately forced Artigas out, although he resisted bitterly for more than three years. In 1820 he withdrew to Paraguay, where he spent the rest of his life. He died Sept. 23, 1850, in Ibiray near Asunción.

Artigas is regarded as the chief creator of Uruguayan independence although that movement was not finally won until several years after his retirement. *See* URUGUAY: *History*. (R. H. FI.)

ARTIGAS, a department bordering the Uruguay river in extreme northwest Uruguay, with Argentina on the west and Brazil to the north and east. It was named in honour of José Gervasio Artigas (*q.v.*), the national hero of independence. It is the least densely populated department in the country, with only 70,426 inhabitants (1954 est.) in a territory of 4,682 sq.mi. Artigas, like most of Uruguay, is ranching country. Its rolling, somewhat rocky pastures are good but subject to damaging droughts. A low range of foothills, the Cuchilla de Belén, traverses the southern part of the department. There is some agriculture, with sugar cane, oranges, grapes, forage and maize as the principal crops. The capital city, Artigas, faces Brazil across the Cuareim (or Quaraí) river. (M. I. V.)

ARTILLERY. As constituted in mid-20th century, this category of military weapons was difficult to define exactly. In common parlance it meant all manner of big guns, howitzers and rocket launchers, as distinguished from small arms (*q.v.*) or infantry weapons. The traditional dividing line between the two classes was calibre .60 (0.6-in. or 15-mm.); weapons with bore diameter greater than calibre .60 were considered artillery and those with smaller bores were considered small arms. But there were many exceptions to the rule. Portable rocket launchers like the bazooka with its 2.36-in. (60-mm.) bore or the larger 3.5-in. (89-mm.) superbazooka and recoilless rifles of 57-mm. and larger were sometimes classed as small arms because they were used by infantry troops and could be handled by one or two men. Small mortars also were often classed as infantry weapons rather than artillery. At the other end of the scale, the large rockets and guided missiles that emerged during and after World War II added a whole new category of weapons capable of performing an artillery function but operating on principles radically different from conventional guns and howitzers. Between these two extremes were rapid-firing aircraft weapons ranging from machine guns of calibre .30 and .50 up to larger pieces of 20 mm., 37 mm. and even 75 mm., plus aircraft rockets. With these aircraft weapons the distinction between infantry use and artillery use was, of course, not applicable. Though similar to their ground counterparts, these aircraft weapons were usually not designated as artillery but as aircraft armament, just as the big guns mounted on tanks were referred to as tank armament.

The term artillery also described the personnel or artillerymen who transported and served the weapons and the branch of the army to which such personnel were assigned. Organization of units and employment of weapons are discussed later in this article and also in the articles ARMY and TACTICS. For the differences between military gunnery and naval gunnery *see* GUNNERY, NAVAL. For a description of artillery shells, fuzes and propellants, *see* AMMUNITION, ARTILLERY; FUSE; PROPELLANTS. For an exposition of the physical laws governing the flight of projectiles, *see* BALLISTICS.

During World War II and the years that followed, artillery matériel was subject to various classifications. A simple method was to divide it into two basic groups: (1) mobile or field artillery which was capable of comparatively quick transfer from one place to another; and (2) immobile artillery, or artillery of position, being heavy cannon which, once emplaced in a permanent seacoast or fortress defense, was rarely moved. Because World War II was a war of rapid movement over wide areas, mobile artillery assumed greater importance while immobile artillery of the old fixed-fortification type tended toward obsolescence. A new type came into service during the 1940s and took the name of self-propelled artillery. It consisted of guns or howitzers mounted on armoured tanklike carriages that moved under their own power instead of being towed by truck or tractor.

In field use there were many specialized classes of artillery such as mountain guns or howitzers, tank and antitank guns, and antiaircraft weapons. Each class had its own peculiar requirements and its own technique of fire. In terms of army organization, artillery was sometimes classed as battalion, regimental, divisional, corps or army. As their names indicated, these classes steadily increased in calibre, range and effectiveness from battalion up to corps, though army artillery was usually a composite of all types. Another common practice was to classify artillery pieces as light, medium or heavy. The lines dividing these classes differed among the armies of the world. The U.S. army placed in the light category artillery weapons up to the 105-mm. howitzer; in the medium category the 155-mm. howitzer; and larger guns and howitzers in the heavy category. (See *Artillery in World War II* below.) Still another classification described the various types of artillery weapons as guns, howitzers, heavy mortars or rocket launchers. Briefly, for arms of like calibre, the gun was a long-barrelled, long-range weapon with a relatively flat trajectory (path followed by the projectile); the howitzer had a shorter barrel, less range and followed a moderately arched trajectory; the mortar had a very short barrel, short range and a hairpin-shaped trajectory because of the high angle at which it was fired. Intermediate types possessed some of the characteristics of both guns and howitzers and

were referred to as gun-howitzers. Rocket launchers were simple tubes or guiding rails that held the rockets before firing and aimed them in the desired direction.

I. ORIGIN AND EARLY HISTORY

Before the invention of gunpowder, artillery in France and England signified bows and arrows. Thus, the weapons of the Genoese crossbowmen at Crécy (1346) were referred to by Jean Froissart in his account of the battle as *leur artillerie,* while Roger Ascham in *Toxophilus* (1545) wrote that, "Artillerie nowadays is taken for two things: gunnes and bowes." Confusion resulted from changes in meaning undergone by certain technical words in the course of time, changes to which may be ascribed much of the uncertainty existing as to the origin and evolution of many instruments in modern use. Thus, the "gunnes" of Ascham meant to Geoffrey Chaucer no less than three different objects, as indicated by his employment of the earlier form "gonne" to designate: a throwing machine (in his translation of *Le Roman de la rose*); a missile (*Legende of Good Women*); and finally a cannon (*Hous of Fame*). Naturally, the uninitiated, discovering the word "artillerie" (or "gonne") in a work of early date would be inclined to endow it with its modern meaning, and so perhaps to surmise the existence of ordnance at a period considerably antedating that of its actual introduction.

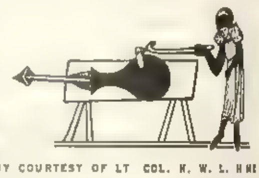
Obviously, before the artillery of modern times could take its shape, some agency for propelling missiles, at once simpler and more powerful than the physical means employed in the earlier forms of projectile weapons (*see* ENGINES OF WAR), had to be discovered. Such an agency was gunpowder, a mixture of three ingredients—sulfur, charcoal and saltpetre. The English friar Roger Bacon (*c.* 1220–*c.* 1292), described certain of its properties in a volume written sometime prior to 1249. But there is nothing in that work to indicate that he possessed any idea of its possible use as a propellant. He realized that it could and would explode, and might, as a result, be adaptable to the arts of warfare, but further he apparently failed to speculate.

The question as to who took the next step and used the explosive mixture as a propellant, thus making it gunpowder, has been a matter of endless debate among historians. The 19th-century belief that the Chinese or the Hindus invented cannon lost ground after publication of Col. H. W. L. Hime's *Gunpowder and Ammunition* in 1904, exposing errors in translations of ancient documents. Some historians gave credit to the Arabs for devising a crude type of firearm called a *madfaa* as early as 1304, but the evidence to support this thesis was far from conclusive. Researchers found no convincing evidence that any of the crusaders from Europe encountered firearms in all of their many battles with the Turks during the middle ages.

In Europe the name most often mentioned by 19th-century historians as inventor of cannon was that of an obscure German monk of the 14th century known as Berthold Schwarz or Berthold the Black, apparently so named for his interest in the black art of alchemy. Substantial evidence to support this view was altogether lacking. As for the date of the invention of cannon, the best we can say is that it probably occurred between 1320 and 1325. The claim that the year 1313 introduced cannon to the world rested on the following widely quoted entry in the official records of the city of Ghent for that year: "Item, in this year the use of *bussen* (*i.e.,* "cannon") was discovered in Germany by a monk." After study of the original Ghent records in 1923, Sir Charles Oman in his classic work, *The Art of War in the Middle Ages, A.D. 378–1485* (1924), rejected this evidence on three counts: (1) it was a marginal note in the early copies of the record book; (2) it was not a contemporary entry but had been added later; and (3) it actually appeared under the year 1393 in the earliest copy.

1. Early Artillery (14th Century).—Though precise data as to the origin of cannon were lacking, historians found numerous references to the use of firearms by the English, Scots, Germans, Moors and others in the second quarter of the 14th century. As early as 1327 a drawing of a crude cannonlike device appeared without explanation in an English manuscript in the library of Christ Church, Oxford (*see* fig. 1). Most historians concluded that the battle of Crécy, often quoted as the earliest occasion where gunpowder was employed by the military in projectile weapons, must yield priority to other instances of the use of this destructive combination. But all references to artillery in the early years, including Crécy, were fragmentary and inconclusive.

2. Construction.—The outlines of the piece shown in the Christ Church manuscript explain why early cannon were commonly described as *vasi* or *pots-de-fer* ("iron pots") since its contours are identical with those of a modern vase; viz., bulbous base, narrow curving neck and flaring mouth. They likewise indicate its characteristics with respect to size, shape, manner of mounting and firing better than words could accomplish. And despite the obvious unsuitability of an arrow-type projectile for discharge from a firearm (an unsuitability belied in some measure by the successful development more than 400 years later of harpoon guns for whale fishing), this unhandy combination continued in use for well over two centuries. As time passed, cannon balls of roughhewn stone were employed, followed by cast-iron and wrought-iron balls.



BY COURTESY OF LT COL. H. W. L. HIME

FIG. 1.—EARLY TYPE OF CANNON

As to method of manufacture, the first artillery pieces seem to have been constructed of cast bronze or brass and were very small. Soon after, guns of wrought iron appeared, but not of cast iron since the technique of producing successful casts with ferrous metals did not develop until the 15th century. It reached England relatively late. Research by the British Iron and Steel institute fixes 1509 as the approximate date of the first iron cannon to be cast in England. Wrought iron, because of its slag inclusions, was far from a perfect medium in which to work, but it was long employed for lack of something better, and with it guns of substantial dimensions were produced. The usual practice was to arrange one or more layers of hand wrought-iron bars or rods side by side in a circle, then weld their abutting surfaces together like the staves of a barrel (whence the name gun barrel). To fill the interstices that remained, molten lead was often employed. Then, to give added strength and solidity, wrought-iron rings were driven onto the sheaf of welded bars so closely together from breech to muzzle as to cover entirely that which lay beneath.

Since it was difficult to attach an integral breech piece to this open-ended affair, many cannon so constructed were made breech-loading, though in some instances a hollow bronze cylinder, open at one end and closed at the other, was driven into the breech end of the welded barrel to serve as a powder chamber. Thus the enclosed end of the cylinder became the breech of a completed muzzle-loading cannon. For the breechloaders, powder chambers were supplied by welding to the open breech of the barrel tube a skeletonized cylinder of a diameter somewhat greater than that of the bore, cut away at the top and open at the forward end where it joined the barrel to become a rearward extension thereof. Into the cutaway top of this barrel extension, a movable, ready loaded chamber (powder container) could be dropped. This was simply a hollow vessel closed at one end, with a handle attached for easy manipulation. The rear (closed) end of this cylinder abutted against the closed (breech) end of the welded-on barrel extension. The forward end lined up with the breech end of the barrel tube. The ball was pushed into the open rear end of the barrel, then the movable powder chamber dropped into position behind.

Early nomenclature for firearms of all kinds, as indicated, was confusing. The English words cannon and gun (the latter can be traced back to about 1350, the former at least to Froissart) derive respectively from the Latin *canna* ("a tube") and *mangonel,* a powerful pre-gunpowder stone-hurling engine of war. Mortar has always been applied to a short, stubby cannon because of its resemblance, in its earliest forms, to the conventional vessel of the chemist and apothecary. Bombard was also used to describe early guns, large and small. Thus *bombardes-à main* ("hand bombards") are mentioned as in use at the siege of Bonifacio in 1420, while the diminutive form *bombardelle* appears in an earlier Italian

manuscript of 1381. However, after the art of casting great guns was mastered during the last decades of the 14th century, bombard came gradually to apply only to large pieces of artillery now long obsolete.

The efficiency of these crude specimens of artillery was severely limited (were any limitation necessary) by the "serpentine" powder of the day, which was truly a powder and not the grained substance now known. This required no little skill in handling, and an experienced gunner could develop the full capabilities of a piece where a tyro was likely to blow it up (and himself and crew into the bargain) or else be plagued either with a succession of misfires (the charge failing to burn when the match was applied) or a series of "overs" or "shorts" (the missile falling beyond or on the near side of the target). The whole secret lay in the fact that the finely divided mixture would form into a solid mass practically impermeable to flame when rammed too vigorously, or simply fizzle out like a weak firecracker when seated with insufficient force. Only when put in place with the delicate touch gained from long experience, which left it loose enough for a flame to spread quickly through its fine interstices, yet packed tightly enough to build up what constituted, in effect, an explosion rather than a progressive, but ballistically impotent, conflagration, did it really perform satisfactorily. (*See* GUNPOWDER.)

Further, it was soon discovered that such powder, when mixed beforehand and transported for any distance, tended to separate out, the heaviest component (sulfur) settling to the bottom, and the lightest (charcoal) rising to the top. Fired in this state, it was even more than ordinarily inefficient. The result was that the gunner had to mix the several ingredients on the field of battle, a precarious maneuver in view of the fact that the lighted matches of the musketeers were everywhere about. Thus he became a man apart, feared and shunned by all and sundry. For more than three centuries following the invention of the cannon most artillerists were civilian specialists called "artists." The French army employed civilian "artists" as cannoneers as late as 1800.

3. 15th Century.—Dating, however, from about 1429, one finds record of an important achievement—the "corning" of powder. Briefly, this involved the mechanical incorporation, in fixed proportions, of the three ingredients so firmly and intimately that there was no longer any tendency for them to become dissociated on handling, plus the added feature of turning out the finished product in "grains" of various sizes according to the purpose for which intended; viz., small grains for small guns, large grains for large ones. Large grains fired in a small piece burned so slowly that much of the charge left the muzzle unconsumed, its effect thus entirely wasted. Small grains in a large piece burned so fast as to develop dangerous pressures in the chamber, and sometimes even to burst the tube, before the ponderous shot ahead could fairly get started. The grains of the new product, though of about equal weight, were irregular in shape, hence could not ball up into a conglomerate mass as did the serpentine. Instead, the interstices so necessary to the swift propagation of the flame were thus automatically provided, and the explosion of each successive charge was uniform and highly effective. So effective was it indeed that though the employment of corned powder in small arms went rapidly forward, it was a full century before its adaptation to artillery had become complete; for the cannon of the period were wholly unequal to the strains set up by this improved propellant, nor was the art of gun founding able to meet the situation thus arising for many decades yet to come.

The 15th century saw the manufacture of enormous bombards that still rank among the largest pieces of artillery ever built. It is significant that they appeared in such widely separated regions as Scotland, Belgium, Turkey and Russia. Edinburgh castle's "Mons Meg," of uncertain origin but probably built before 1500, weighed five tons and could throw a 19½-in. iron ball nearly a mile. "Dulle Griete," the giant 13-ton bombard of Ghent, had a 25-in. calibre and fired a 700-lb. stone. The largest of all, the "Tsar Cannon" of Moscow, had a 36-in. bore, weighed nearly 40 tons, and was cast by Andrei Chokhov in 1586. Some of the most formidable bombards of the 15th century were those used by the Turks when they captured Constantinople in 1453. All these were smooth-bore pieces. Rifling the bores of artillery pieces was attempted as early as the middle of the 15th century, but apparently without much success. Serious efforts to develop it are said to have been made by the Swiss Jean Maritz during the early 1700s, but manufacturing difficulties held it in abeyance until the 19th century.

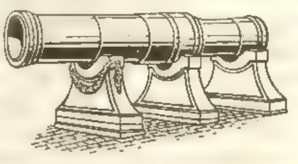


FIG. 2.—DULLE GRIETE, GHENT, BELG.

Despite the inventive genius constantly devoted to the development of firearms, artillery included, the 15th century waned and closed without these new agencies of warfare having gained sufficient recognition to receive special classification either on the basis of relative size or tactical employment. Thus, Francesco di Giorgio Martini, writing a few years prior to Charles VIII's expedition against Naples (1494), describes ten different types of firearms, and adds that this by no means exhausts the list. Yet he draws no distinction between cannon and shoulder weapons. To him the bombard, 20 ft. long and firing a 300-lb. ball, falls in the same category with the scopietto, which measured 24–36 in. over-all and discharged a missile weighing ½ to ¾ oz. All were to him "artillery."

Nevertheless, a differentiation, among the heavier pieces at least, was taking place, if insensibly, and before the 15th century ended field artillery as distinct from the more ponderous and relatively immobile artillery of position may be said to have been born. Prior to this time, field artillery consisted simply of such guns of its siege train as an army was able to bring into the field. But the Italian wars, which Charles VIII initiated, stimulated French ingenuity to the development of means whereby guns could be endowed with a fair degree of mobility. These included the uniform mounting of ordnance on wheeled carriages (in place of the clumsy sledges theretofore prevalent) and the employment of well-trained horses, rather than the slow-footed oxen, as draft animals. Thus, while the Italians and Spaniards were still entrusting the transport of their artillery to that sluggish beast, and Maximilian I possessed draft teams sufficient to move but half of his siege train at a time, the sturdy French horses were learning to draw heavy cannon on level roads at a pace equalling the marching speed of cavalry.

But the French were not alone in their efforts to make artillery a mobile arm. Indeed, the Italian Bartolomeo Colleoni (d. 1475) is credited with being the first captain to develop a true field artillery tactic, locating his light guns in the rear of other elements, and firing through gaps in these which were opened at a given signal. Nevertheless, such practices were far from general, and most Italians considered Charles VIII's employment of field guns as something quite revolutionary. Fortunately for him, he so outweighed his adversaries in the quantity and quality of his artillery, not to mention pieces exceeding in calibre any yet known in Italy, all mounted on scientifically designed carriages and operated by trained gunners, that his superiority in that arm was maintained throughout all the earlier Italian campaigns, its reputation alone being in some instances, as at Fornovo, sufficient to undermine enemy morale.

It was during this century that artillery acquired a characteristic which it had lacked (to the considerable limitation of its effectiveness); namely, the trunnions whereby the gun tube was affixed to its mount, about which it could be rotated when an increase or decrease in range was desired, and through which the shock of discharge was transferred in large measure to the carriage. In earlier types, the simple cylindrical tube or barrel was commonly set into a heavy wooden framework, a stout cross member of which abutted against the breech and received from it the impulse of recoil. This crude design did not by any means yield without a struggle to the more advanced one in which trunnions figured, for the obvious reason that it was much easier to cast a plain tube than one from which two excrescences projected outward opposite one another at right angles to the tube axis. But the advantages of the trunnions were so outstanding that the

simpler but less efficient trunnionless type was finally replaced entirely by its more adaptable competitor.

4. 16th Century.—The French successes naturally stimulated others to emulate their efforts. The younger duke of Ferrara, whose father (d. 1505) had long been interested in ordnance and was one of the few of noble birth to engage in its production prior to 1500, turned out specimens in considerable numbers and of increasingly high quality. In 1509 was witnessed the destruction by his artillery of the dread Venetian fleet which had proceeded up the Po to within a short distance of his capital, an event which contributed enormously to the increasing prestige of artillery in general. Only the following year, the French accomplished the reduction of Legnano chiefly through the agency of two of Ferrara's guns of tremendous size, the casting of which he had personally superintended.

As the 16th century neared mid-point, the artillery policies of all great nations of that day, which had been developing without rhyme or reason for more than 200 years, appeared ready for a complete overhaul. Calibres and varieties of guns approached infinity; standardization was unknown. To reduce this chaos to some sort of system, Charles V of Spain decreed, in 1544, a total of seven models of cannon which would thenceforward be made for, and used by, the armies of his empire. These included a cannon (40-pounder), a cannon-moyen (34-pounder), two types of 12-pounder culverins, two 6-pounders and a 3-pounder falcon. Early pieces were often named after birds of prey. The French were quick to follow suit, and in 1550 Henry II issued an edict restricting the number of calibres to 6, the heaviest a 33-pounder weighing, with its carriage, 8,000 lb., and drawn by 21 horses; the lightest a 2-pounder to which two horses were assigned. Later (1584) two additional types were permitted, a 12- and 24-pounder (calibres which the Spaniards had found useful in the Low Countries).

The practice of the day involved the transport of these pieces muzzle foremost, their massive trails dragging on the ground behind, and their equine motive power stretched out in single file, so that each gun when on the march must have occupied interminable yards of road space. Nor did the passage of time simplify the picture, for the 33-pounder of 1633 had increased in weight by 400 lb., and the horses drawing it now numbered no less than 25, though some progress could be recorded in the fact that the weapon was now hauled trail foremost.

These gestures of Charles of Spain and Henry of France, while aimed in the right direction, left much to be accomplished. Thus, among a few of the shortcomings of contemporary artillery may be mentioned their want of limbers, a complete lack of uniformity among carriages, the quite common and often disastrous failure to provide the artillery train with any spare parts for emergency repairs (save an occasional extra wheel) and so on. No specific powder charges were established, though practice favoured the use of a weight of the very indifferent propellant then current which actually equaled that of the shot. Three sizes of powder were employed—large-grained for the heavier guns, small-grained for the lighter and a still finer type for priming all varieties.

During this century the art of gun founding was introduced into England by ordnance-minded Henry VIII after he had been forced by lack of a home industry to reach overseas and employ the famous Fleming, Hans Poppenruyter, to supply him with nearly 150 pieces of varying calibres, including the celebrated set of bombards known as the "Twelve Apostles." He likewise imported (*c.* 1515) foreign armourers and established schools of instruction for native artificers. Nor was he entirely satisfied with the ordinary solid shot then in use, but undertook to augment these with crude types of shell described by a contemporary as: ". . . hollow shot of cast yron, stuffed with fire-works or wild-fire: whereof the bigger sort for the same had screws of yron to receive a match to carry fire kindled, that the fire-work might be set on fire to break in small pieces the same hollow shot, whereof the smallest piece hitting any man would kill or spoil him." Here we see, in the type "stuffed with fire-works," the beginnings of the explosive shell and, in that containing "wild-fire," of incendiary projectiles.

In the German states, calibre simplification was not then carried as far as in France. Thus there is illustrated and described in Napoleon and Gen. Ildefonse Favé's work on artillery as in use during the period 1550–1600 no less than 11 varieties of mobile cannon, from a little 1-pounder to a huge piece discharging a 94-lb ball. Further, there existed among all of these, save the very smallest, subclassifications which brought the total to the impressive figure of 40, the heaviest of which called for no less than 60 horses to get it into motion.

But far more important than the number of cannon types employed in France, Spain or Germany at this time were the premonitory rumblings then coming out of Italy to predict the birth of a new science—ballistics. Given written expression by the famous mathematician Niccolo Tartaglia (*q.v.*) in works which appeared in 1537, 1546 and 1551, these constitute the first recorded scientific approach to the theory of gunnery as distinguished from the prevailing rule-of-thumb practice. And although in large measure incorrect, this author's ideas on the trajectory of a cannon ball (previously held to be a straight line from gun muzzle to some point in space, after which the missile fell suddenly to earth) were so far ahead of his day that he justly deserves the title of first ballistician.

5. 17th Century.—By this time some artillerymen were beginning to realize that certain practices, though hoary with age, lacked foundation in logic. Thus it had from the very beginning been customary to make the barrels of cannon (as contrasted with mortars; howitzers came along later) outlandishly long to afford opportunity for the complete combustion of the serpentine powder originally employed in them. Then came the introduction, and finally the general adoption, of corned powder, which burned faster and more evenly, and accomplished as much in short barrels as its predecessor had in long. Yet for a long time barrels continued to be made long, no one quite knew why. Similarly, though some of the earliest cannon to be cast with trunnions had these located where they properly belonged—with their long axes in the same plane as that of the long axis of the bore—practice soon departed from this, and trunnions came to be set on a level with the bottom of the bore and remained so situated for generations. As a result there was at each firing an undue strain on the trail of the piece which, as the strength of powder increased, frequently gave way under the force so applied. Not until the latter half of the 18th century was this patent error generally corrected.

During the first half of this century, Gustavus Adolphus of Sweden introduced (1626) his famous leather guns, so named because the external casing of the barrel was of that material. The bores, however, were metal (copper) tubes. Every effort was made to curtail weight, and as a result that of the gun itself, apart from its light carriage, came to but 90 lb., and the piece could easily be drawn by two men. Designed as the last word in mobility, it possessed that qualification in high degree but embodied at the same time a deadly disadvantage; for on repeated firing it became so hot that a new charge would often ignite spontaneously. This led to its supersedure (1631) by matériel of more substantial, it less mobile, character, and further effort to develop a truly light artillery remained in abeyance until resumed in the century following by Frederick the Great.

During this period, calibres of French cannon underwent further change by reason of the adoption of various foreign pieces. This resulted in an increase in varieties from six to seven, the largest piece now being a 48-pounder, then ranging downward through 32-, 24-, 16-, 12- and 8-pounders to one of 4 lb. But here all order ended; for the kingdom was divided into a number of artillery districts, each commanded by a lieutenant general of that arm. And the cannon and all their accessories of one district differed from those in the next. Each calibre of gun employed wheels of a size unlike that used by any other calibre. Spare carriages were taken into the field, but those of one district would not mount the guns from another. In but one feature was simplification of the practices of the preceding century evident: powder had become standardized in grains of a single size and, ballistically speaking, this evidenced a retrogression. But here again, specimens from the several districts were likely to exhibit marked variations in strength, though for the most part a charge of but two-thirds the weight of the ball now accomplished what had required weight for weight a

century earlier, the quality of powder having improved to this extent over the intervening years.

6. 18th Century.—This century was to witness a period of marked ordnance activity on the part of all major European nations. Among the high lights may be noted the abolition in France (1732) by General Valière of all mobile pieces above the 24-pounder, thus making that calibre the nation's heaviest field weapon. Coincidently he decreed a uniformity in the methods of fabricating cannon never before attempted. Unfortunately, his efforts ceased at this point. There remained as many different designs of gun carriages as there were manufacturing arsenals. Axletrees continued to be of wood. Limbers, when used at all, were too low, and draft horses were still strung out in single file ahead of the guns to which they were hitched.

Turning to England, we find the groundwork of modern ordnance theory and practice laid by Benjamin Robins (1707–51), whose *Principles of Gunnery* (1742) exploded ancient superstitions about the nature and action of gunpowder and the flight of projectiles, and formed the basis of all later scientific studies in these fields. Gunners were now for the first time able to measure with considerable exactness the muzzle velocities of projectiles delivered by their pieces as a result of his invention of the ballistic pendulum, a device whereby the energy of a projectile suddenly halted in its flight could be accurately estimated and translated into terms of velocity.

By the time of Robins' death, strenuous efforts were again being made on the continent toward developing a truly efficient mobile ordnance (field artillery). Thus, the Seven Years' War found Prussia in the midst of a series of experiments with pieces weighing from 80 to 150 times as much as the balls they fired, while by 1762 the Austrians had standardized on guns all 16 calibres long (i.e., with tubes 16 times their diameter in length), all 115 times the ball in weight, all firing missiles carefully cast to a true spherical form and with so little windage (excess in diameter of bore over that of projectile) that they achieved excellent results with powder charges not exceeding in weight one-third that of the missile.

Other nations were not insensible to these developments and, by 1765, Jean Baptiste de Gribeauval, who became chief inspector of artillery in 1776, had commenced yet one more revamping of French matériel. This resulted in even further reduction in the number of different calibres employed in the field, these now totaling but three, the heaviest a 12-pounder, the others carrying 8- and 4-lb. balls respectively. These were all 18 calibres long and 150 times the weight of the shot for which designed, thus continuing the now well-established trend toward reducing the length and weight of field pieces. Once again, much attention was paid to securing balls of true sphericity and correct diameter, thus making possible the same reduction in powder charge as had been effected by Austria, i.e., to one-third that of the ball in weight.

Another innovation was the introduction, for field use, of a light howitzer of 6-in. bore. Yet another, which marked a real milestone in artillery progress, was the disposition of draft horses in double files in place of single file. Six horses now sufficed to draw the 12-pounder—four for the lesser sizes, a pleasing contrast with the numbers required a century earlier. Limbers, then casually in use, became standard equipment. These were large, six-wheeled affairs, but higher and more serviceable than those of Valière. The limber box (a combination receptacle for ammunition and seat for some of the gunners) failed, however, to gain acceptance despite Gribeauval's strenuous efforts, though he did succeed in establishing interchangeability of wheels and other parts, and in introducing iron axletrees, elevating screws, tangent scales and prefabricated cartridges. These replaced the old loose powder and shot and embodied carefully weighed powder charges sewed into cloth bags, to one end of which a shot was securely affixed, the whole being swept down the bore of the piece and seated at the breech by a vigorous movement of the rammer. They were, however, in no sense a new invention, Adolphus having used them with some success in the century preceding.

Other of Gribeauval's achievements included the classification of land ordnance into three well-defined groups (field, siege and coast defense) according to the purpose for which intended. In the first category he endeavoured unsuccessfully to educate his countrymen to the importance of horse artillery, an ultramobile element first employed by Frederick the Great (1759), designed to maneuver with cavalry in the manner in which field artillery operated with infantry. Not, however, until after the outbreak of the French Revolution was such a unit found in the French service, its counterpart, incidentally, appearing in England at approximately the same time. The latter years of the 18th century are marked by the invention (1784) by a British lieutenant (later general), Henry Shrapnel, of a form of spherical case shot for use against personnel, destined to bear his name and to supplant most other types of artillery ammunition for well over a century to come.

7. 19th Century.—This century was to record a series of advances in ordnance practice so brilliant as to render the artillery in use when the century closed probably ten times as efficient as that which marked its opening. Contributing factors included progress in chemistry, mechanics, metallurgy, optics and associated sciences which made possible: (1) the perfection of a workable rifled cannon, long sought by ordnance engineers but never before successfully attained; and (2) the adaptation to rifled cannon of elongated projectiles which (a) because of their more streamlined form were less affected in flight by wind than were the round balls they displaced; (b) by reason of the stabilizing spin imparted them by the rifling grooves, flew much straighter; and (c) being decidedly heavier than a ball of like diameter, ranged much farther than the spherical form. But to propel these heavy bolts, more and better powder was required. This was made available through the researches of Capt. (later Gen.) Thomas J. Rodman (U.S.A.), who produced a "mammoth" brand of powder shaped as large hexagonal prisms and perforated to permit the flame to burn outward as well as inward from the prism surface. Thus the initial violent evolution of gas from the burning grains, followed at once by a progressive decrease in gas production as the surface of unburned powder exposed to the flame was steadily curtailed, gave way to a situation where, though the external surface of the grains constantly shrank, internal surfaces, provided by the perforations, were enlarging with each instant. The final effect was to stretch out materially the period of mass evolution of gas and of high pressures on the chamber walls, and so to develop, in effect, a prolonged steady push against the base of the projectile rather than a sudden blow, with maximum stresses much moderated. But before this achievement had been recorded, workers in other fields, attacking the problem from different angles, had succeeded in producing guns both of bronze and cast iron, the two materials used almost exclusively in the founding of cannon for centuries past, and which possessed high physical characteristics that enabled them to withstand pressures formerly unthought of. In the case of bronze, this result was attained by the admixtures of certain proportions of phosphorus to the copper-tin alloy. However, the achievement came too late (1870); the day of the bronze cannon was over.

Toward enlarging the capabilities of iron pieces, two Americans offered solutions. One, a civilian engineer, Daniel Treadwell (1791–1872), designed a built-up, muzzle-loading cannon in 1841, which he evidently believed his exclusive invention, though his claims have been disputed in favour of a Frenchman (M. Thiery), said to have developed a similar piece in the 1830s. Treadwell's gun, in its final form, consisted of a central tube of cast iron or steel, surrounded by a series of wrought-iron or steel hoops, shrunk on after heating, and in some instances united also by screw-threaded joints. This basic method of construction was later successfully adopted in the United States by Robert Parrott and in England by William Armstrong (q.v.) and Blakely and, save for improvements in means and materials, became the modern practice. But Treadwell received no adequate encouragement from the military, and died disappointed and discouraged.

The other system was developed about 1845 by Rodman and was quite different. Instead of casting guns as solid cylinders of iron later to be bored out, the ancient and honourable method, he cast them hollow about a removable core through which a stream of water was slowly passed. Cooling thus took place from within

outward (the external walls were kept warm meanwhile), succeeding layers of metal from bore to surface undergoing compression as those overlying slowly shrank, thus accomplishing, but by a radically different method, just what Treadwell had done. But cast iron, like bronze, had had its day as a material for gun construction and, though Rodman's process saw active application for two or three decades, it eventually was forced to give way to others in which the piece was built up (à la Treadwell) from successive layers of steel. The advantages of this material for cannon fabrication had long been recognized, but until the mid-19th century, no methods of producing it in the quantities and qualities required had been evolved.

FIG. 3.—U.S. 6-LB. FIELD GUN USED IN THE CIVIL WAR

Alfred Krupp (Germany) was the first to produce a successful all-steel gun. Drilled out of a single block of cast metal, it was the marvel of its day. The first specimen to be shown at a world exposition, a modest six-pounder displayed at London in 1851, attracted universal attention. Within ten years Krupp was producing guns of 8-in. bore and larger, all from solid blocks of cast steel. However, after other makers had demonstrated the possibilities of all-steel guns on the built-up (hooped) system, he gradually adopted that method of fabrication also.

The military world was now (1850s) enjoying rifled cannon which projected heavy missiles to what were then considered stupendous ranges, this as a result of the improved powders and stronger gun tubes. Capt. Paul le Boulengé of the Belgian army invented an instrument (chronograph) which constituted a material improvement for measuring velocities over Robins' ballistic pendulum. But it still lacked accurate means of estimating the forces exerted by the burning powder gases against the breech of a weapon. As a result, current methods of determining the strength of the walls required to withstand these were based more on trial and error than anything else. But here again Rodman came to the rescue by designing a gauge which permitted very accurate calculation of the pressures engendered.

Three factors were still lacking to make the gun the super-efficient engine it became with the advent of the 20th century. These were: (1) a successful system of breech loading; (2) a satisfactory smokeless powder; and (3) means to dampen the forces of recoil when the piece was fired so that it could be relaid on its target quickly and accurately. In respect of the first, breech-loading cannon of fair efficiency had been produced as early as the 1840s by Cavalli, a Sardinian officer, and Baron Wahrendorff of Sweden. The time was ripe for such a development, for as guns became longer and heavier, the mechanics involved in getting the charges properly inserted into their ponderous muzzles, ramming them home, then returning the pieces to their firing positions and relaying them upon their targets became increasingly complicated, and a satisfactory system of breech loading more urgently indicated. During the 1860s and 1870s, several such methods were perfected simultaneously in France (Col. C. Ragon de Bange), Germany (Krupp), Spain (Freyre) and the United States (Broadwell).

In England during the 1850s, Sir William Armstrong and Sir Joseph Whitworth had developed wrought-iron, built-up, rifled cannon. Whitworth's was noteworthy in possessing a hexagonal bore. The American Civil War of 1861–65 offered the first opportunity for a mass trial of rifled guns and, to a limited degree, of breechloaders as well. Even so, the vast majority of cannon used in that conflict were smooth-bore cast-iron (plus some brass muzzle-loaders, although steps to modernize these by reaming out the original bore and driving into it a rifled tube of wrought iron or steel were taken during this period and continued for a number of years thereafter. Wire-wound guns in which countless turns of fine wire coiled under tension replaced shrunken-on hoops as reinforcement for a relatively thin central tube had already been under development from about 1855 but were yet to receive the recognition later accorded them.

In the field of propellants (*q.v.*) black powder, which reigned supreme, produced so much smoke as to obscure both firer and target after a heavy volley, or broadside, and left such heavy fouling in a gun bore as to require frequent cleaning if accuracy were to be maintained. In addition, it was, despite the notable achievements of Rodman and others, far from under full control in the matter of the chamber pressures it developed. A new propellant, smokeless, without residue and capable of being harnessed over a much wider range of its activity was urgently indicated. The answer appeared at hand when, during the 1860s, Baron General von Lenk conducted a prolonged field test of guncotton (first compounded a few years previously) in the Austrian artillery. But a lack of stability and consequent tendency to spontaneous explosion in storage led to its eventual rejection. So it remained for the French chemist Paul Vieille (1887) to harness this unruly substance by gelatinizing it into colloid form with the aid of suitable solvents, and thus make available to the military world the propellant it had so long awaited.

And now the science of mechanics, which had already solved the problem of breech loading, came again to the aid of the artilleryman and gave him a gun mount so ingeniously designed as to permit it to absorb the tremendous recoil developed when a modern piece is fired, this without rearward movement of the carriage or displacement of the barrel from its original position once action and reaction had their effect. This was accomplished by suspending the gun tube proper in a cradle and interposing between the two compression cylinders, heavy spiral springs or other means of accumulating, as the barrel swept rearward, the energy necessary to return it to its original position, once recoil effects had been dissipated, rather than transmitting these to the carriage. Prior to the development of such a system, the gun and its mount, to which it was rigidly affixed, recoiled to distances varying with the calibre of the piece and charge employed, then had to be brought back "into battery" by human effort and pointed again at the target. With the perfection of such counterrecoil mechanisms, artillery finally acquired all the more important characteristics which it possessed at the commencement of World War I.

There was a revival of interest in the rocket during the closing years of the 1700s and particularly in the early part of the 19th century, after the weapon had been neglected as an implement of war for several centuries. In their wars with the British, for instance, native Indian troops used rockets. During the Napoleonic Wars British warships launched rockets in their attacks on continental coastal cities, and the field forces used them in both siege and battle. The "rocket's red glare" in "The Star Spangled Banner" was not a phrase penned by Francis Scott Key without foundation in fact. In the bombardment of Ft. McHenry, defending the city of Baltimore, Md., ships of the attacking British fleet were equipped with rocket-firing devices which were used with spectacular effect. *See* ROCKETS AND GUIDED MISSILES.

II. WORLD WAR I

The types of artillery equipment in use by the three major powers involved at the beginning of World War I (Great Britain, France and Germany) did not vary to any marked degree. All

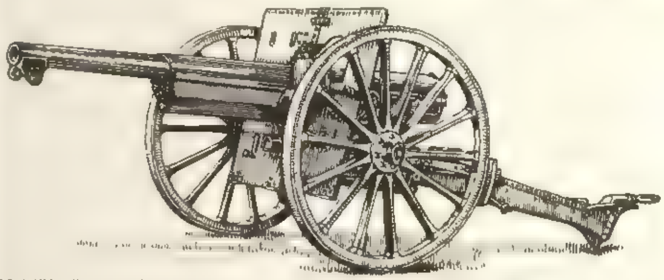
proved deficient in range, the British equipment being initially at a particular disadvantage in this respect. It will be apparent that there were, however, important differences in the allotment of the artillery as between divisions, corps and armies and in the aggregate proportions of the various types of equipment. The Germans had a marked advantage in the possession of a large number of howitzers capable of assisting in both field and siege operations. Both Britain and Germany had six-gun batteries while the French batteries were of four guns. All three countries had divisional artillery commanders, but France alone had an artillery commander at corps headquarters. Viewed in the light of subsequent experience, it would seem that both the British and French tactical doctrines of 1914 unduly emphasized the importance of mobility to the detriment of firepower. The German doctrine appears to have been better balanced in this respect and the Germans also realized more fully the necessity for co-ordination of combined action of the artillery with that of the other arms. All three countries had grossly underestimated the quantities of ammunition which would be required. The British reserve was calculated upon a basis of a probable expenditure of 7 rounds of the biggest field-pieces per day, but in World War I the actual daily expenditure for some light guns occasionally rose to 500 rounds or more. No country had fully appreciated the effect upon artillery power of the development of railways, motor traction, aircraft, telegraphs, telephones, radio and survey.

1. Evolution of Equipment.—The British field artillery stood the test of the war well and the minor defects which appeared were easily remedied. The proportion of medium and heavy artillery was vastly increased, the equipments adopted being 60-pounder and 6-in. guns and 6-in., 8-in. and 9.2-in. howitzers. Superheavy howitzers of 12 in. and upward and guns on railway mountings of 9.2 in. and upward were brought into use. Much publicity was given the German "Big Berthas," howitzers with bore diameters of 42 cm., or nearly 17 in. And mortars, a type of weapon which had long been discarded, made their reappearance for the war of position. The ranges of all weapons were increased, field artillery ranges rising to about 10,000 yd. and even more in the case of French and German equipments; the greatest range (viz., 76 mi.) was attained by the German 21-cm. guns used to shell Paris (*see* BIG BERTHA). The British field guns, which had started the war with shrapnel ammunition only, were supplied with high-explosive shell in addition before the battle of Loos. Shrapnel was abolished for 4.5-in. howitzers, and in the heavier pieces high explosive was almost exclusively used. Smoke shells were introduced for the lighter types of guns and howitzers in 1916. In July 1915 the Germans first employed gas shells, and this type of shell came into general use in steadily increasing numbers.

It is noteworthy that the supply of gas ammunition never equaled the demand and that the use of gas was still in its infancy at the end of the war (*see* CHEMICAL WARFARE). An advance in the control of fire was effected by the development of observation from aircraft. Intercommunication was improved by the more extended use of the field telephone and of radio. Survey, sound-ranging and flash-spotting units were provided for co-operation with artillery. The lighter types of artillery were still generally horse drawn in 1918 although trucks were used, especially by the French, to transport a portion of their field artillery. The heavier pieces were drawn by motor tractors of various designs ranging from the four-wheel-drive truck to the caterpillar.

2. Evolution of Organization and Command.—A comparison of the development of artillery organization and command in the British, French and German armies shows that, notwithstanding their initial differences and the separate lines of evolution which were followed, all three arrived at similar solutions of fundamental problems. The changes introduced may be summarized as follows: (1) Artillery command was centralized as much as was consistent with effective control. This proved the best means of co-ordinating action, of economizing force and of concentrating fire at the right time and at the right place.

Centralization of control was often carried to excess, however, in the western theatre. This change in the system of artillery command entailed an increase of artillery headquarters staffs. (2) The necessity for a strong reserve, in the hands of the higher command, of both field and heavier types of artillery led to the creation of large numbers of artillery units outside the organization of formations. In 1914 the proportion of field artillery to infantry in an army was about 6 guns to 1,000 rifles. By the end of World War I the proportion of all types was about 10 guns and howitzers per 1,000 rifles, roughly 6 field, 2 medium, $1\frac{1}{2}$ heavy and $\frac{1}{2}$ superheavy. (3) The allocation of equipments to formations was based upon their ranging powers and their degrees of mobility. Thus, field artillery (in the United States light artillery) was seldom allotted to formations higher than the division; medium and heavy artillery were normally allotted to corps, while superheavy guns were directly under armies. (4) The corps was recognized



DRAWING BY ANDRE JANDOT FROM J. E. HICKS, "WHAT THE CITIZEN SHOULD KNOW ABOUT OUR ARMS AND WEAPONS"; BY COURTESY OF W. W. NORTON & CO., INC.

FIG. 4.—FRENCH-DESIGNED 75-MM. FIELD GUN, MODEL 1897, USED BY U.S. FORCES IN WORLD WAR I

as the most suitable formation for the control of counterbattery work and special staffs were provided for this task. The divisional artillery of an infantry division, U.S. army, consisted of two regiments each of six batteries of four 75-mm. guns, one regiment of six batteries each of four 155-mm. howitzers and one trench mortar battery.

3. Evolution of Tactics.—The evolution of equipment and organization and the evolution of tactics were, of course, interdependent. It was naturally on the western front that artillery tactics were most fully developed. During the first operations in 1914 sharp lessons were learned. It was soon evident that because of the hitherto unrealized power of small-arms fire in defense, attacks must be well prepared by artillery. Tactical mobility had, in fact, become dependent upon firepower, but neither side had the artillery or the ammunition to provide firepower in adequate measure. At Le Cateau the British learned the disastrous results of attempting close support of infantry with guns disposed too close to the foremost troops. The early engagements also demonstrated the necessity for distributing guns in depth in defense and for concealing them if they were to avoid destruction. The need for increased quantities of medium and heavy artillery was soon apparent.

During the trench warfare of the winter of 1914–15 new developments began to take shape. Attempts were made to engage targets by night and to provide defensive barrages. Air observation of artillery fire also found favour. The employment of barbed-wire entanglements introduced a new task for artillery in the preparation of infantry attacks.

The operations of 1916 and 1917 were based upon the fact that, given sufficient artillery and ammunition, limited advances of 2,000 or 3,000 yd. at a time could be almost guaranteed. Enormous concentrations of artillery supported every attack. Thousands of tons of ammunition were fired daily during an operation on a front of a few miles. Surprise continued to be sacrificed, for the artillery carried out preliminary bombardments often lasting four or five days. Rolling barrages of great depth and heavy counterbattery fire were the unvarying accompaniment of the actual advances. Such were the methods of artillery action adopted in the battle of the Somme (1916), the French attack at Verdun (1916), at Arras (1917), in Gen. Robert Nivelle's attack on the Aisne (1917), at Messines and in the third battle of Ypres. The Germans, in their attack at Verdun in 1916, had endeavoured to obtain some measure of surprise by reducing the preliminary bombardment to ten hours and, in Field Marshal Edmund Allenby's attack

at Gaza, measures were successfully taken to deceive the Turks who might otherwise have been warned of the British plan by the five days' preliminary bombardment. But none of the commanders had as yet appreciated the paralyzing effect of the brief and intense hurricane bombardment of short duration which was adopted in 1918.

It became apparent, however, that a drastic change in tactical methods must be made if decisive success was to be obtained. The defender could, in great measure, counter the form of artillery support then in vogue, heavy as it was, by suitable adjustment of his infantry tactics; the ammunition expenditure entailed proved too great a strain on industrial resources; and the effect of the fire on the ground was such as to create new obstacles for the attackers. In the defense, artillery action had taken the form of "counterpreparation" to break up impending attacks by neutralization of hostile artillery and of stationary barrages close to the foremost trenches to repel assaults once they were launched.

The advent of tanks had an important bearing on artillery tactics. At the battle of Cambrai it was demonstrated that tanks could carry out tasks which had previously fallen to the artillery. They had a very great demoralizing effect; they could create gaps in barbed wire; and they could neutralize small-arms fire. The employment of tanks had a considerable influence in bringing about the abolition of lengthy preliminary bombardments and the consequent simplification of the problem of ammunition supply. The battle of Cambrai further proved that effective artillery support could be given, by means of survey methods, without previous registration.

The German successes on the western front in 1918 were largely the result of skillful artillery tactics, for the development of which Colonel Bruchmüller was chiefly responsible, the element of surprise being thus safeguarded. Their new tactics had first been employed, and with marked success, at the battle of Riga in Sept. 1917. Secrecy was observed in the preliminary concentration and other arrangements. Each attack was preceded by a short hurricane bombardment of a few hours' duration designed to produce moral rather than material effects and containing an element of surprise in the repeated withdrawal of fire to the forward defenses after it had apparently passed on. Gas and smoke shell were extensively used; counterbattery fire was heavy. The advances were supported in their initial stages by intense concentrations on enemy strong points and the infantry was boldly followed up by field artillery.

A counter to the German artillery tactics was eventually devised by the French in Champagne. Careful artillery counterpreparation was carried out for some time before the German attack which the enemy had not been able to keep secret. Troops were thinned out in the forward zone, in which the first shock of the attack was to be absorbed, and the main line of defense was organized in the rear, the artillery fire being adjusted to correspond with these arrangements.

A hurricane bombardment of 15 minutes, followed by a creeping barrage, was adopted with complete success by Allenby in his final break through the Turkish lines in Sept. 1918.

During 1918 the use of concentrations of fire increased. Gen. Charles P. Summerall (U.S.A.) in 1918 first tried out concentrating the fire of all his divisional artillery in front of one infantry brigade at a time when the infantry could go no farther with the help of the rolling barrage. Later, in the November attack in the Argonne, he gave his army corps heavier artillery support than had been seen up to that time. The system of artillery command at last admitted of centralization or decentralization according to the varying situation. A return was made to a long preliminary bombardment when the British 4th army attacked the Hindenburg line in September; surprise had then ceased, however, to have great value because of the extent of the Allied offensive and the disappearance of the enemy's reserves.

When operations ceased, the art of tactics was on the threshold of a new era of development which had been ushered in by the renewal of mobility, by the introduction of tanks and by the mechanization of transport. (*See* also TACTICS: *World War I.*)

(J. N. K.; M. B. H.)

III. BETWEEN WORLD WARS I AND II

The art of gun design and manufacture languished during the two decades from 1918 to 1938. In France, Great Britain and the United States the antiwar spirit was strong, leading to disarmament treaties that nourished the hope that war would never occur again. Commercial firms that had manufactured munitions for World War I were denounced as "merchants of death" and in all the western democracies the development of new or improved weapons was hampered by lack of interest and lack of funds.

In the United States there was no commercial manufacture of field artillery and even the government arsenals were barely able to keep from closing. The U.S. army devoted most of its limited artillery funds to development of a 37-mm. antitank gun, a 75-mm. field gun to supersede the French 75, a 75-mm. pack howitzer and a 105-mm. howitzer.

The Germans, being disarmed, had to limit their developments to theory except insofar as from time to time they found an opportunity, through relations with the U.S.S.R., to carry out some experimentation with the Russians. The Russians, from the beginning of the organization and armament of their World War II army, showed a tendency to develop new tactical ideas and therefore to modify their artillery armament to suit these ideas. In general, their artillery doctrine differed from the French one of using large concentrations of fire primarily under one command and leaned toward the splitting up of their artillery in small groups assigned directly to infantry units. The Italians, while closely following the French theory, showed a decided tendency after World War I to put into practice German theoretical solutions of artillery problems, insofar as their financial status would permit rearmament.

The Abyssinian campaign in 1935–36 gave the Italians the opportunity to test their theories with respect to the supporting artillery for infantry in mountainous countries and the relationship between artillery and aviation and the means of transport of artillery. The Italians steadily developed the idea that the infantry commander should have immediately available the lesser calibres needed for the assault. Therefore, besides small mortars which could be carried forward by the troops by hand, they had in each infantry regiment one battery of 65-mm. mountain guns carried on pack mules.

1. Spanish Civil War.—The Italians discovered that in many instances larger calibres could not keep up with the infantry and at other times could not be emplaced where they could reach enemy positions well up on a mountain. They therefore came more and more to use bombing by airplane as a means of supplementing their artillery fire. The Italians found that pack and horse-drawn artillery were essential because the use of mechanized and motorized artillery was greatly limited by the lack of roads and the difficulties of the terrain. A large and well-equipped road-building force enabled them to make a much greater use of mechanized and motorized artillery than would have been the case with other armies with nothing more than their customary organization and equipment for this purpose.

The result of the German, Italian and Spanish experimentation in battle in the Spanish civil war showed the need for increase in all types of artillery and, in general, larger calibres. The cannon as an aviation weapon was shown to be a necessity. The cannon as the principal tank weapon was shown to be an essential for all heavy combat. In other words, just as artillery weapons had steadily increased as essential parts of the armament of infantry units so had the artillery become an essential part of aviation and tank armament. There is little doubt that the experience in Spain with a few airplanes armed with a cannon of around 20 mm. was the reason for the large use of airplanes armed with cannon by the Germans in World War II.

In all assaults in Spain in 1938 and 1939 the artillery bombardment was followed by aerial bombardment from heavy bombers upon the same targets as those upon which the artillery had fired. The accompanying artillery fire during the infantry assault was dispensed with. There were no rolling barrages and no concentrations on the first objectives of the infantry. Artillery concentrations were on the rear of this objective. The accompanying artillery fire

was furnished by aviation and by tanks armed with cannon. The aviation attacked with light bombs and machine guns by dive bombing, one plane after another from one flank of the objective to the other. It repeated this until the infantry had reached the point where further air attacks became dangerous.

Tanks with cannon were distributed at intervals in the infantry assault wave. Their guns furnished fire on all critical points encountered by the infantry during its advance. Wherever the infantry was held up, a number of tanks with cannon and dive bombers would make a concentrated attack. The use of tanks with cannon of around 47 mm. and up frequently resulted in the 37-mm. antitank guns proving ineffective, this because of the longer range of the tank cannon and its bigger bursting charge. The consequence was that the 65-mm. mountain gun was more and more used as an antitank gun. Besides its greater range and bigger bursting charge it could, being a much smaller target, be emplaced in positions which an ordinary field gun of 75 mm. or 77 mm. could not use. This was because the latter was such a large target it would be destroyed by the enemy's fire.

The first German antiaircraft artillery used in the Spanish civil war was a 77-mm. gun. These guns were in mechanized batteries of four pieces each. It was soon found that the range was not great enough, the trajectory not flat enough and the bursting charge not large enough. Therefore, a new piece of 88-mm. calibre, and of greater length than the 77-mm., was constructed in Germany and shipped to Spain. This piece could reach any bomber with a war load. All sighting apparatus was set and corrected by remote control from a range-finding party some distance from the guns and in a position such that it had a good view of the target. These guns, instead of being emplaced in line, were emplaced at the four corners of a square probably 109 yd. to a side. When not firing on targets in the air the guns were used to fire at targets on the ground. Their long range made them particularly effective not only against positions well up on mountains but also against the rear areas including all the roads over which enemy tanks, artillery and supplies had to advance. The guns were field artillery in that they could be put in or out of battery in a relatively short period of time and could move easily over roads and also over terrain which was not too difficult.

As the result of their experiences in Spain the Germans and Italians made a number of changes in their armament and tactics. It may be said that these changes had to do with increasing the proportion of artillery to infantry, making cannon a part of aviation armament, increasing the number of tanks with cannon and the calibre of these cannon, and improving the communications between all parts of their armed forces so that the maximum benefit could be derived from their artillery fire for both offensive and defensive purposes.

By the use of cannon in aviation and in tanks it can be said that in addition to "fire and movement," that is, fire to cover movement, there is "fire in movement." "Fire in movement" was the basis of the success of the German armoured or panzer divisions in 1939 and 1940.

IV. COASTAL ARTILLERY

In the 19th century coastal artillery (or seacoast artillery as it was sometimes called) attained a position of substantial importance as a special branch of artillery. All leading military powers prepared their coastal cities, harbours or strategic waterways for defense against naval attack by the installation of both fixed and mobile artillery weapons capable of firing high-explosive shells at enemy ships far out to sea with a fair degree of accuracy.

Big coastal guns were elaborately protected from hostile fire by being emplaced behind thick earth and concrete fortifications, and were sometimes effectively camouflaged. In most instances these fortifications were equipped with underground storage rooms for supplies and had their own electrical systems. In some of them complicated mechanisms were installed to raise the guns above ground long enough to fire; the huge gun tubes were then quickly retracted into their concealed and well-protected pits. To control the fire of long-range coastal guns, observation posts were set up at points along the coast and were connected by wire communications to the gun position. The data reported by observers were processed in the plotting room and the target's location, speed and direction of movement were calculated. Just before World War II the British army experimented with radar for the control of coast artillery batteries.

During the first quarter of the 20th century the United States installed seacoast batteries at all its principal harbours, in the Panama Canal Zone and at naval bases in its island possessions. The coast artillery guns ranged in size from 3-in. pieces to huge 16-in. weapons and included 12-in. mortars that were designed to drop heavy shells on the armoured decks of warships. These weapons were supplemented by antiaircraft guns, searchlights and guns of smaller calibre for direct fire at high-speed motor torpedo boats and small submarines.

Coast artillery assumed such importance in the United States after the turn of the century—when memories of the Spanish-American War were still fresh—that the army created a coast artillery corps (CAC) separate from the field artillery in 1908. In addition to the coastal guns it had responsibility for the installation and control of submarine mines and in World War I took on a significant new responsibility when antiaircraft defense became a military necessity.

Coast artillery played only a minor role in World War I, and during the years that followed it gradually declined further as the bombing plane came into its own. As time passed, it became apparent that coastal batteries could be bombed too easily from the air, attacked from the rear or bypassed altogether. Early in World War II the fall of Singapore, Britain's mighty bastion in the far east, came as a severe shock to the whole western world. The Japanese had managed to approach Singapore through the jungle on the land side, where its defenses were weak, while its great coastal guns silently pointed out to sea. Even before the fall of Singapore the U.S. army had reorganized its forces along lines that dropped the CAC as a separate entity, at the same time that horse cavalry was supplanted by armoured forces. By the end of World War II most military authorities were convinced that fixed seacoast artillery had become obsolete. The U.S. army dismantled many of its old seacoast fortifications and turned them over to nearby cities to be used as public parks. (*See* COAST DEFENSE.)

(H. C. T.)

V. ARTILLERY IN WORLD WAR II

The lines of battle, the areas they encompassed, the speed with which situations changed, the frequent combinations of land, sea and air elements in one engagement and the co-ordinated, simultaneous use of all arms and services in every campaign makes an abbreviated outline of the part played by a single arm in World War II an impossible task.

In previous wars—which were primarily wars of position and which progressed from battle to battle in a relatively confined sector of the globe—it was possible to trace the progress of organic artillery and point out the spectacular and victorious roles it played in combat, often occupying the spotlight of attention as the sole active participant for long periods. Such continuity of participation during World War II cannot be narrated in a brief account because (1) the use of artillery as a weapon was not confined to an organic unit like the field artillery or the coast artillery corps, but was shared by the infantry and armoured cavalry (later known as armour or armoured forces) as well as the artillery; and (2) combat artillery units were engaged, withdrawn and re-engaged in so many different areas and participated in such varied types of operations that it is difficult to separate their action in a short description from the work of the rest of the fighting team. In substance, the story of such artillery is the story of World War II.

In general, the employment of organic artillery followed the techniques foreshadowed by the Spanish civil war. Despite widespread feeling early in World War II that aircraft bombing might supplant artillery, the role of guns remained significant. Experience demonstrated that the most concentrated bombing of which planes were capable could not achieve the same results as pounding by heavy artillery. For attacking strongly fortified positions,

only artillery was able to maintain constant, accurate, highly destructive fire on specific targets, unaffected by darkness or bad weather.

As rapid-firing guns and howitzers were used to lay down thunderous barrages, consumption of artillery ammunition reached astronomical proportions. In the first two days of the attack on Monte Cassino in Italy, U.S. artillery units fired something like 11,000 tons of ammunition. Total output of artillery ammunition in the United States from 1940 to 1945, counting all sizes from 20 mm. to 240 mm., totaled nearly 1,000,000,000 rounds, exclusive of bombs, grenades, mines and billions of rounds of small-arms ammunition.

It was estimated that if all the 105-mm. shells produced in the United States had been laid end to end they would have extended twice around the earth at the equator. The variety and complexity of both weapons and ammunition were so great that only broad classifications may be described here. Detailed data are in the countless technical manuals prepared by the armies using each type of weapon.

Artillery development in World War II moved forward along several distinct lines. All nations increased the calibres of their mobile field weapons as horses and mules were replaced by trucks and tractors that helped solve the problem of mobility. Before this time the weight of mobile artillery had been inescapably governed by the power of horses, with even the 75-mm. gun requiring a team of six or eight horses. Typical of the trend toward larger calibres was the U.S. army's action to replace its 75-mm. guns, modeled on the famous French 75 of World War I, by the 105-mm. howitzer.

The trend toward more powerful guns was also motivated in large part by the appearance of tanks with thicker and tougher armour. At the same time, heavy weapons such as railway guns, coast defense guns and guns of permanent fortifications such as the Maginot and Siegfried lines fell into the discard. (*See* FORTIFICATION.)

No new gigantic weapons appeared in World War II to compare with the much-publicized Paris gun of World War I. Instead the Germans brought forth new types of weapons, long-range V-1s (flying bombs) and V-2s (rockets) that were launched against England and Allied-held points on the continent during the latter part of 1944 and early 1945. Meanwhile Allied forces introduced the proximity fuze that automatically exploded artillery shells when they came within range of their target. Used first at sea for antiaircraft fire, the proximity fuze proved equally effective in firing on ground troops.

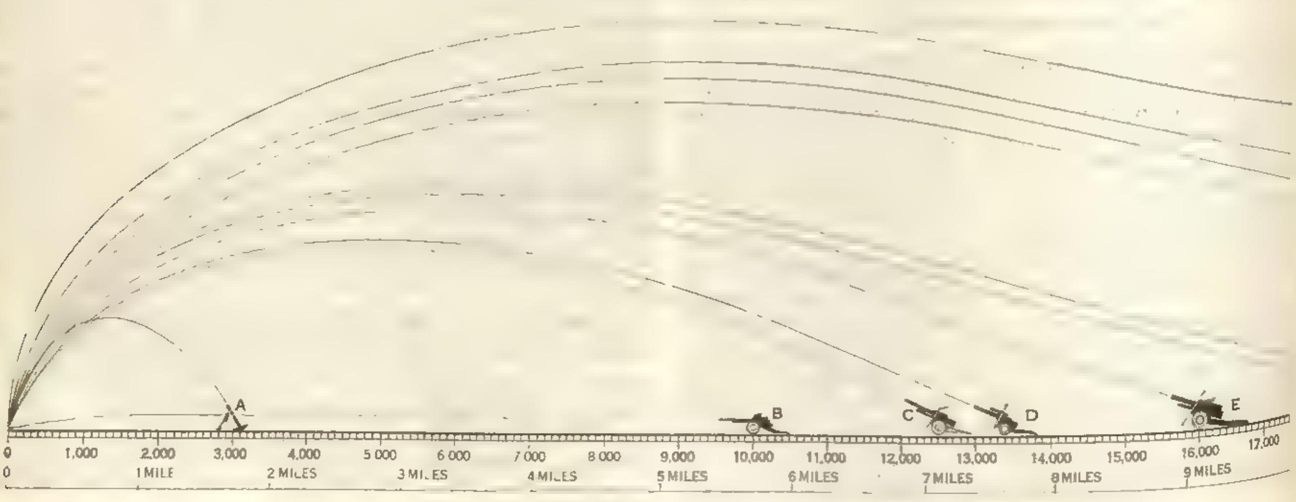
Because World War II was a war of rapid movement, altogether different from the trench warfare of 1914–18, the demand was not for bigger guns but for lighter, more mobile weapons. Rapidity of fire and speed of movement and emplacement were prime considerations. To achieve these ends, gun carriages were equipped with pneumatic tires and with improved bearings and springs to permit towing at high speeds. A major innovation along this line was the introduction of self-propelled artillery. Instead of being towed by horses, trucks or tractors or carried on the backs of mules, guns and howitzers were mounted on tank chassis or on other vehicles so they could travel speedily over rough terrain and fire without taking a long time for emplacement. In the Pacific ocean area the terrain and limited area of many of the islands did not provide opportunity for use of highly mobile matériel but did require powerful weapons for dislodging well-entrenched troops. Following the lead taken by British forces in their attack on Sicily, guns and rocket launchers mounted on ships were used in conjunction with aircraft bombing to provide a beach barrage that blasted coastal areas with high explosives before troops went ashore. Of equal importance were three classes of artillery that had come into prominence during the years since 1918—antiaircraft, antitank and aircraft—all of which played a major role in World War II. If to these are added recoilless rifles and the bewildering array of rocket launchers that appeared during the 1940s the multiplicity of artillery weapons at the disposal of field commanders is obvious.

Lines of classification between guns and howitzers and between small arms and artillery were frequently blurred, and weapons were not easily separated into mutually exclusive categories. The old U.S. army classifications of field artillery and coast artillery gradually lost their importance and after the war were merged into one branch known simply as artillery. Under these circumstances the weapons are best discussed under the headings of light, medium and heavy artillery, with additional special classes such as mortars, antiaircraft guns, aircraft weapons, recoilless rifles and rockets.

1. Light Artillery.—In the U.S. army the light artillery classification included the 37-mm. antitank gun and other weapons up to the 105-mm. howitzer. The chief weapons in the British field artillery ranged from the small 2-pounder (37 mm.) to the 3.7-in. howitzer and the famous 25-pounder (88-mm.) gun-howitzer. These guns and howitzers were used as mobile field artillery, towed or self-propelled, and as tank or antitank (AT) weapons.

The 37-mm. AT gun was light in weight (about 900 lb. when mounted on its carriage) and was maneuverable in areas denied to other artillery. Its maneuverability combined with its rapid rate of fire (25 rounds per minute) and seven-mile range made it a versatile weapon, equally useful for firing canister at enemy troops or armour-piercing shells at light tanks. In the Pacific area its maneuverability made it a favourite with troops. It served as a field gun on its own two-wheeled mount and was also placed on tanks, armoured cars and light trucks as a tank destroyer. Although used in large numbers, the 37-mm. steadily lost ground during World War II because it was too small to penetrate the armour of any but the lightest enemy tanks.

To defeat the new heavier armour, a Soviet army gun of 45 mm. had been battle-tested in Spain. The British 57-mm. (6-pounder) AT gun was a still more powerful weapon, but effective antitank fire demanded guns of even greater range and striking power. The U.S. army adopted a 3-in. AT gun with special ammunition that could penetrate more than three inches of tank armour at



2,000 yd.

The Germans used 50-mm. and 75-mm. antitank guns but also went a step further with their famous 88-mm. triple-threat gun that could fire against tanks, planes or personnel with equal ease. This gun was also mounted in heavy German Tiger tanks used in North Africa in 1942–43 and could knock out Allied tanks before they could come within range with their 75-mm. guns. The U.S. army's 90-mm. field gun failed to achieve the flexibility of its German rival.

Two howitzers rounded out the class of U.S. light artillery weapons, the 75-mm. pack howitzer and the 105-mm. howitzer. The former was the U.S. counterpart of mountain guns employed by armies of other nations. It could be towed by a small truck or could be disassembled and carried in several loads on the backs of mules up mountain trails inaccessible to larger guns. Special containers known as paracrates were made for dropping the parts of this weapon by parachute from airplanes. Far more important was the 105-mm. howitzer, produced for the armies of the United Nations in greater numbers than any other artillery piece. It could throw a 33-lb. high-explosive shell as far as seven miles and was supplied with a dozen types of ammunition, including an armour-piercing round, smoke shells and shells filled with propaganda leaflets. More ammunition was fired from the 105-mm. howitzer than from any other piece of U.S. artillery in World War II. Mounted on a motor carriage, it first saw service with British troops in 1942 in North Africa, where it was nicknamed "The Priest" because of the pulpitlike appearance of its machine-gun mount.

The light artillery of the Soviet army in World War II included a 76-mm. gun and a mountain howitzer of the same calibre. A new 85-mm. gun appeared in the postwar years.

2. Medium Artillery.—As there were only two U.S. army weapons in this classification during World War II, the 155-mm. howitzer and the 4.5-in. gun, the classification tended to merge with heavy artillery. Because of their long ranges and heavy firepower these weapons were used to blast road intersections and other fixed targets and to harass the enemy's lines of communication. The 155-mm. threw a 95-lb. projectile for a maximum range of nine miles. The range of the 4.5-in. was over 12 mi., but as its projectile weighed only 55 lb. it was far less effective than the howitzer. The standard medium weapons of the German army included a 100-mm. gun and a 150-mm. howitzer. As a close support weapon the latter was mounted on an armoured vehicle and nicknamed "Grizzly Bear."

Soviet medium artillery included a 100-mm. gun, a 122-mm. gun and a 152-mm. gun-howitzer. The latter two weapons were made more mobile in the postwar years and could be emplaced more rapidly.

3. Heavy Artillery.—Like the other two classes, heavy artillery of British-U.S. forces included both guns and howitzers—the 155-mm. gun, the 6-in. (153-mm.) and 8-in. (203-mm.) guns, the 8-in. howitzer and the 240-mm. howitzer. Despite the size and weight of these pieces they could be towed by powerful tractors and thus shared with the lighter weapons the all-important quality of mobility.

The 155-mm. gun, familiarly known as "Long Tom," fired a 95-lb. projectile at the rate of one round per minute for a distance of 15 mi. The huge 8-in. gun had a barrel 34 ft. long and weighed, with its carriage, over 30 tons. It fired a 240-lb. shell for 20 mi. at the rate of one per minute, and was considered the Allied answer to the German 170-mm. gun. Because of its great size and weight the 8-in. gun and its mount had to be broken into two sections for transport over roads and bridges. Cranes were needed for assembling the piece and handling the heavy shells.

The 8-in. howitzer fell between the 8-in. gun and the 155-mm. howitzer in terms of weight of projectile (200 lb.) but below them in range (about ten miles). It could be mounted on the same carriage as the 155-mm. gun. The 240-mm. howitzer was the largest piece of artillery to see action with the U.S. army, throwing a 360-lb. projectile for 15 mi.

Soviet heavy artillery included a 203-mm. howitzer, 210-mm. gun, 280-mm. howitzer and a huge 305-mm. howitzer. In the postwar years the Soviet army adopted a newly designed 203-mm. howitzer that had much greater range (28,000 yd.) and could be emplaced in a matter of minutes. It was probably capable of firing atomic shells.

4. Mortars.—World War II mortars formed a distinct class of weapons used by front-line troops to lob projectiles over hills or other obstacles into enemy positions at short range. They were simply constructed and sufficiently light in weight to be disassembled and carried by foot soldiers for short distances. Unlike other artillery weapons they had smooth bores (with some exceptions), were loaded from the muzzle and fired fin-stabilized projectiles. They needed no recoil mechanisms as their closed breech ends were fitted to a base plate on the ground.

Best known of the U.S. army mortars was the 60-mm. that weighed only 43 lb. and had a range of from 200 to 2,000 yd. The 81-mm. mortar that replaced the British 3-in. Stokes mortar of World War I had a range exceeding one mile. Two large mortars of 105 mm. and 155 mm. were produced in limited numbers for the U.S. army, and one gigantic piece dubbed "Little David" was constructed in 1944. Its bore diameter of 914 mm. ($36\frac{1}{4}$ in.) was precisely the same as that of the "Great Mortar of Moscow" built in the 16th century. It fired a projectile weighing 3,700 lb. and, unlike most mortars, had a rifled bore. Designed to destroy subterranean fortifications and industrial targets, it came too late in the war to be of use and was generally considered an impractical weapon.

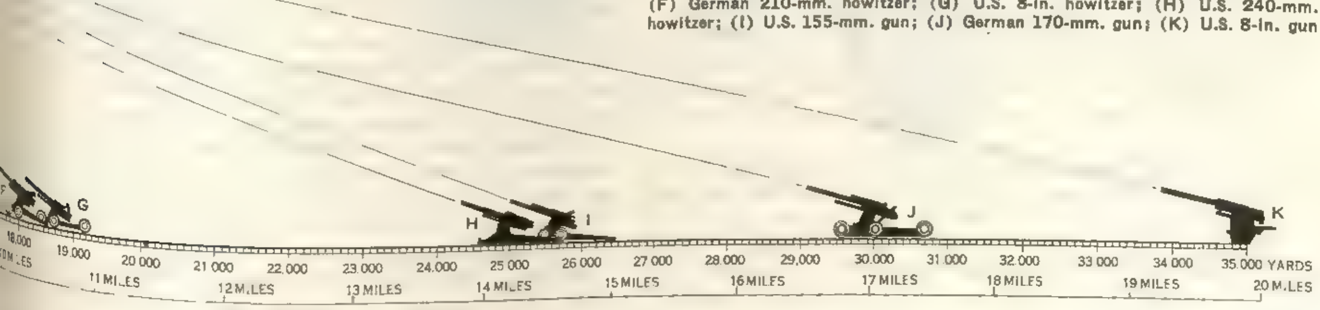
Another exception to the rule that mortars had smooth bores was the 4.2-in. chemical mortar. The projectile for this weapon had a rotating band (or driving band in British terminology) of soft copper measuring slightly less than the bore, allowing the shell to slide easily down the tube. Upon firing, the force of the propellent gases expanded the rotating band to engage the rifling and cause the shell to spin in flight, thus improving its accuracy.

During World War II and the postwar years, the Soviet army emphasized heavy mortars and classed them as artillery rather than infantry weapons. Its 240-mm. mortar was the largest calibre weapon of its type in use by any army in the 1950s.

5. Antiaircraft Artillery.—Adaptation of aircraft to military purposes during the early years of the 20th century naturally stimulated development of special weapons to shoot them down.

FIG. 5.—DIAGRAM ILLUSTRATING THE COMPARATIVE RANGES OF TYPICAL WORLD WAR II WEAPONS

(A) U.S. 81-mm. mortar; (B) British 57-mm. antitank gun; (C) U.S. 105-mm. howitzer M2; (D) British 25-pounder gun-howitzer; (E) U.S. 155-mm. howitzer; (F) German 210-mm. howitzer; (G) U.S. 8-in. howitzer; (H) U.S. 240-mm. howitzer; (I) U.S. 155-mm. gun; (J) German 170-mm. gun; (K) U.S. 8-in. gun



For zeppelins and low-flying planes, rifles and machine guns sometimes did the trick, but for planes flying at greater altitudes guns of artillery calibre had to be called into play. As the mounts for field guns were not designed to permit them to be pointed toward the sky they were at first emplaced on hillsides or on built-up mounds of earth for high-angle fire.

During the latter part of World War I guns adapted for anti-aircraft (AA) fire were placed on special mounts that permitted them to point skyward, and some were mounted on heavy trucks to give them mobility. But, lacking the elaborate fire-control instruments needed for accurate AA fire, the guns were quite ineffective.

The military airplane raised a whole series of new and baffling problems for gun designers and artillerists. The guns not only had to point nearly straight up but also had to be designed for speedy aiming and firing. An accurate estimate of the height of the enemy plane had to be made so the time fuze could be set to explode the shell when it reached the same height as the plane. A direct hit on a high-flying plane was more than any gunner could expect, but exploding a shell within lethal range of a plane was within the realm of possibility. The plane's speed had to be estimated to enable the gunner to determine how much "lead" he had to take, just as a duck hunter must learn to aim ahead of his intended victim. High-velocity weapons obviously were needed to reduce to a minimum the time required by the shell to reach its target, for as much as 20 sec. might elapse before a shell reached an altitude of 20,000 ft., and in 20 sec. a fast plane might travel more than two miles. Rapidity of fire was desirable to give the gunner more chances to hit his fleeting target; long range became essential as attacking planes flew at 20,000 ft. or higher; and giant searchlights were needed to play on the sky at night and catch enemy planes in their beams. Light, medium and heavy AA guns were all needed to provide defense against planes coming in at low, intermediate or high level.

In World War II AA guns up to 40 mm. were rapid-firing automatics, while the larger guns were loaded by hand or with a mechanical rammer. The smaller calibres were supplied with tracer ammunition that enabled the gunner to see where his shots were going. Extraordinary progress was made during the 1930s and the 1940s in developing machines for speedy computation of the mathematical problems involved in AA fire.

Elaborate height finders, computers and directors of great mechanical complexity were introduced to improve the effectiveness of all AA guns. British forces effectively employed radar as early as 1940 to alert ground and air forces to the approach of enemy planes. Perhaps the most sensational new ordnance device of the 1940s was the VT or proximity fuze containing a miniature radar set that automatically exploded shells when they came within range of an airplane.

The AA weapon most used by British and U.S. forces in World War II was the automatic 40-mm. gun originally produced and sold internationally by the Bofors firm of Sweden. It proved as effective for close-in AA defense of naval vessels as for service on land, and was employed in both air-cooled and water-cooled models, firing a two-pound projectile to a height of three miles at a rate of 120 rounds per minute. The British navy also used a 2-pounder gun known as a "pompom" and the U.S. army employed early in the war a 37-mm. automatic AA gun that fired a 1½-lb. projectile. These intermediate AA guns were sometimes mounted on half-track vehicles in combination with calibre .50 machine guns. They proved valuable for close support of troops in forward areas and for patrolling roads to protect truck convoys from strafing and bombing. For close-in defense the 20-mm. gun designed by the Oerlikon Machine Tool works in Switzerland was widely used on British and U.S. naval vessels but eventually gave way to larger guns.

The German 88-mm. AA gun, mentioned above in the account of the Spanish civil war, was one of the most successful and most widely publicized weapons of World War II. Its counterpart in the U.S. army was a 90-mm. gun that fired a 24-lb. projectile to a height of more than 30,000 ft. and which soon replaced the older 3-in. gun. The British employed 3.7-in. and 4.5-in. AA guns extensively, as well as rocket projectors known as Z-guns or U.P. (unrotated projectile) weapons.

The largest U.S. army AA gun to see service late in World War II was the 120-mm. (4.7-in.) "stratosphere" gun that fired a 50-lb. projectile to a height of 50,000 ft. Because of its great size and weight it could be used only in fixed positions to defend supply bases in the rear. Of larger calibre but shorter range was the U.S. navy's 5-in. double-purpose gun developed in the 1930s to reach planes at about 35,000 ft. (*See* also AIR POWER.)

6. Gun Carriages and Mounts.—The mount or carriage upon which an artillery piece is affixed for transport and operation is as much a part of the over-all weapon as is the barrel from which the projectile is fired and the mechanism that controls the aim and explodes the propelling charge. Mobile mounts range from the comparatively simple two-wheeled tow carriages to heavy tanks and mammoth trucks. Each mount is designed to provide maximum mobility for the weapon, to overcome as much as possible the obstacles presented by difficult terrain, to provide sufficient strength and endurance to stand up under the terrific strain of combat and to furnish an efficient and rigid firing base for use in unprepared field positions.

The smaller-calibre and lighter-weight artillery pieces, such as those used by the infantry in its own support, are fired either from the shoulder or from bipod or tripod mounts the legs of which rest directly on the ground to support the guns when fired. These pieces require no associated rolling or mobile equipment since they are transported in ordinary weapon carriers or other types of trucks up to the rear area of operations, from which point they are handled manually by the using troops. The 57-mm. and 75-mm. recoilless rifles are examples of the lighter artillery which is fired from the rigid two- and three-legged mounts.

Howitzers and guns in the light and medium artillery class, unless mounted on a self-propelled vehicle, are transported on two-wheeled, rubber-tired tow mounts from which they are fired when set up for action. These mounts, attached to trucks and other types of motorized vehicles, are pulled in the same manner and at relatively the same speeds as an ordinary low-built trailer. Trailer-type mounts are also used for some of the weapons in the heavy artillery category. Designed to support great weights, the mounts are rolled on four or more double, rubber-tired wheels. The tow mounts for the largest mobile weapons, with six large rubber-tired wheels, are provided with flexible axle supports in order to permit adjustment of the wheels when being rolled over the rough, uneven terrain that must be negotiated in combat. The prime movers, or tow vehicles, for these mammoth weapons are armoured tractor vehicles which mount their own smaller weapons for protection against surprise air or infantry attack.

The most radical mounts for practically all ranges of modern artillery are, of course, the tanks and other types of self-propelled armoured vehicles. Tanks and other armoured combat vehicles are, in essence, self-contained mobile forts that provide their own motive power, mount their own assortment of weapons, carry their own ammunition and have thick armour protection for crew and interior equipment. Mechanically revolving turrets permit aiming the main gun or guns in all directions and at the desired elevation. Mounted machine guns enable the crew to defend themselves against close enemy attack in the same manner that infantry protects guns and gunners operating at immobilized artillery firing positions.

Howitzers and guns mounted on self-propelled carriages have a decided advantage over the weapons made mobile by being towed by another vehicle. Like the tanks, these self-propelled carriers are provided with protective armour, stow their own ammunition and mount the guns in such a way that they are capable of being fired within a few minutes of the time they move into position. Furthermore, being dependent upon their own motor power for transportation, they can quickly change position to take full advantage of the unpredictable fortunes of battle. Rough terrain offers no serious difficulty to their mobility because, like the tanks, they are track-laying vehicles.

Another of the self-contained carriers furnishing its own motor power, its own ammunition stowage space and serving as the mount

for a 37-mm. gun is the six-wheeled armoured car. This is primarily a reconnaissance vehicle of great speed when operated over cross-country roadways. It takes the place in modern warfare formerly occupied by the horse cavalry. (*See* also ARMOURED FORCES; ARMOUR, TANK AND AIRCRAFT; ARMOURED CAR; TANK.)

7. **Aircraft Artillery.**—Artillery took to the air in the second quarter of the 20th century, supplementing the calibre .50 machine guns that continued as the main armament of most military planes. Rapid-firing cannon of 20 mm., 23 mm. and 37 mm., firing explosive shells, were widely used both for air-to-air combat and for strafing targets on the ground. Specially designed guns of 75-mm. calibre also were fired successfully from planes at ground targets but they saw only limited combat service. The emphasis in World War II was on long range and rapidity of fire rather than on greater calibre, for in airplanes the weight of gun and ammunition was a prime consideration and rapidity of fire increased the chances of hitting a fast-moving target. Rockets as well as guns were installed in aircraft both for air-to-air combat and for air-to-ground attack. One of the largest was the U.S. navy's "Tiny Tim" which belied its name by measuring 11.75 in., nearly 300 mm., in calibre.

8. **Recoilless Rifles.**—The recoilless rifles developed in serviceable form for the U.S. army in World War II were sometimes classed as small-arms weapons, because they could be handled by one or two soldiers, and sometimes as artillery, because they were of large calibre and fired artillery-type shells. Though ordnance designers in both Europe and the U.S. had long known of the theoretical possibility of producing weapons with no kick or recoil, and Comdr. Cleland Davis of the U.S. navy had actually produced primitive models during World War I, the development of serviceable, lightweight recoilless rifles by U.S. army ordnance experts in 1944 stands as one of the outstanding new ordnance developments of World War II.

The first model adopted was a 57-mm. rifle designed and developed at Frankford arsenal, Philadelphia, Pa. Patented by William J. Kroeger and C. Walton Musser, it was at first known as the "Kro-Musket," and was soon followed by a 75-mm. model, and later by a 105-mm. These weapons were recoilless because exhaust vents in the breech and perforations in the cartridge case permitted some of the propellent gases to escape rearward, thus balancing the forward and rearward thrusts. The great benefit from this design was that it eliminated the need for heavy mounts and recoil mechanisms. A major disadvantage was the back blast that revealed the weapon's position and made its use impossible in airplanes or other confined spaces. The 57-mm. rifle weighed only 40 lb., could be fired from the shoulder and had an effective range of more than two miles. The 75-mm. rifle weighed over 100 lb. and was normally fired from a small machine-gun mount. Within their ranges, these accurate weapons were effective against tanks, machine-gun nests, pillboxes and other field fortifications.

9. **Rockets.**—World War II witnessed the revival of these weapons that were probably of more ancient lineage than cannon but had virtually disappeared from the battlefield in the 19th century. They ranked high among the most significant weapons of the 1940s. While their use in combat generally followed the same lines as conventional artillery, they were radically different in design and capabilities. Being light in weight and readily portable, they were used in airplanes, small landing craft and in ground situations where conventional artillery could not be employed.

When the United States entered World War II in Dec. 1941, there was not a serviceable rocket in its arsenals. In fact, it was not until after the war was well under way that the U.S. began producing rockets.

Within a short time after the rocket project was initiated, however, the much-publicized bazooka (*q.v.*) was in service, giving the individual foot soldier an antitank weapon with the striking power of artillery. Much earlier the British army had employed antiaircraft rockets and the Soviet army had greeted the invading Germans with rocket barrages.

Although all major powers in World War II used rockets, both large and small, the principal pioneers in their development as long-range artillery weapons were the Germans. An American, Robert H. Goddard, had carried on important work in this field in the years between World Wars I and II, but the U.S. armed services had not made full use of his research. German ordnance experts, building on the work of Goddard and their own research, produced one of the most spectacular weapons of the war, the long-range, supersonic V-2s capable of bombarding London from bases on the continent. The V-2s greatly extended the range of artillery bombardment and as long as World War II lasted there was no defense against them except to discover and attack their launching sites. (*See* ROCKETS AND GUIDED MISSILES.)

VI. COLD WAR ERA

After World War II, in an atmosphere of international tension marked by the cold war and by armed conflict in Korea and elsewhere, artillery development continued. Emphasis centred on rapid-firing AA weapons, guns capable of firing atomic shells and rockets capable of carrying either atomic or conventional warheads.

In 1953, just eight years after the first atomic bomb had been dropped on Japan, the U.S. army announced that its ordnance experts had succeeded in developing a long-range gun capable of firing an atomic shell. The first test of this 280-mm. weapon, which could fire conventional as well as atomic shells, took place May 25, 1953, at the Atomic Energy commission's proving ground near Las Vegas, Nev. Its maximum range was about 20 mi. and its weight 85 tons. Suspended between two truck units, the A-gun could be transported over good roads at a speed of 35 m.p.h. and could be speedily emplaced and readied for firing in ten minutes. Later research was directed toward building smaller and more maneuverable atomic weapons. In 1957 the U.S. army announced that it had developed an 8-in. atomic shell.

In 1953 the U.S. army also announced its new Skysweeper, a 75-mm. automatic AA gun equipped with radar that could scan the sky, spot hostile planes miles away, follow their course in daylight or dark and automatically aim the gun. It could fire 11½-lb. high-explosive shells, with proximity fuzes, at the rate of 45 per minute. But the Skysweeper and all other conventional AA guns were rivaled by new rockets that could be guided to their targets by remote electronic controls, even though the target plane took evasive action. Chief among these, for the U.S. army, was Nike, a 20-ft.-long liquid-fueled missile announced late in 1953. So effective was Nike in tests that it was installed in batteries throughout the United States for defense of vital areas. Meanwhile the U.S. navy developed AA missiles to be launched from ships at sea and the air force designed rocket missiles for air-to-air and air-to-ground combat.

While Nike and other missiles were proving their effectiveness in tests against conventional aircraft, scientists began to study an altogether different air-borne threat, the long-range ballistic missile, traveling at many times the speed of sound and carrying a nuclear warhead. The German V-2 rockets of 1944–45 had carried only conventional explosives and had come too late in the war to have a decisive effect. But they had been impossible to intercept and had opened the door to a whole new realm of military weapons that called for complete revision of traditional concepts of time and space in waging war.

After World War II the armed services of all major powers planned, developed and tested such a variety of new rocket weapons, both guided and free, that it is not feasible in this space to list even their names. The U.S. army adopted Corporal as its first combat-ready, guided ground-to-ground missile, and Honest John as an unguided rocket capable of carrying either an atomic or a conventional high-explosive warhead. Redstone was an experimental long-range rocket modeled after the German V-2, but much larger and heralded as the basis for a future 1,500-mi. ballistic missile. Both the U.S. army and the U.S. air force developed 1,500 mi. missiles in the mid-1950s, and in 1958 the air force Atlas missile attained a range of over 6,000 mi. The Soviet Union meanwhile claimed that it had similar missiles. It was generally assumed by rocket specialists that most such weapons were Kitty Hawk types; *i.e.*, early designs that would eventually become obsolete because of the swift advance of technology. Information

concerning new rocket weapons that might be of value to a potential enemy was held in closest secrecy. Emergence of these new weapons, so different from guns and howitzers of the past, was considered by many as marking the beginning of a new era in the world's military history and perhaps as bringing to a close the long and colourful career of traditional artillery as a major factor in warfare. *See* ROCKETS AND GUIDED MISSILES.

VII. ORGANIZATION

1. United States.—To visualize the place of artillery in the U.S. army, it is essential to look at the over-all combat organization and then dwell in more detail upon the artillery sections. The smallest complete combat organization of the U.S. army, comprised of all the arms and most of the services and capable of sustaining itself over an extended period in battle, is the division. A typical infantry division in World War II was built around a nucleus of three infantry regiments. Its artillery element consisted of three light artillery battalions, one medium artillery battalion and one antiaircraft battalion.

In the reorganized infantry division of the post-Korean war period the three infantry regiments were replaced by five battle groups. The artillery battalions remained as the basic tactical and administrative units of the divisional artillery but were equipped to use both atomic and conventional weapons. Battalions were classified as direct support or general support; self-propelled or towed; and as either gun, howitzer or missile units.

Batteries, comparable to infantry companies, were the units that made up the artillery battalions. As the smallest administrative units in the artillery, batteries were capable of operating as separate tactical organizations. As a rule, a battalion had three batteries—two firing batteries and one headquarters and service battery. Firing batteries were designated, according to their weapons, as howitzer batteries, gun batteries or rocket batteries. Other specialized types were observation batteries and searchlight batteries.

In the three-brigade division (*see* DIVISION, MILITARY) announced in 1961 divisional artillery consisted of three direct support battalions armed with 105-mm. howitzers and two general support battalions whose armament would normally be 155-mm. or 8-in. howitzers or missile type weapons.

Above the division was the corps artillery, a flexible organization consisting of artillery battalions attached to the corps. The expression artillery with the corps denoted all artillery responsible to the corps, including that in the divisions subordinate to the corps. Above the corps artillery was army artillery, consisting of units assigned to the army and not reassigned to lower echelons. It generally included the most powerful guns, along with others of smaller calibre, and constituted a strategic reserve to be employed at the army commander's discretion to turn the tide of battle.

2. Great Britain.—In broad outline, the organization of the British artillery in World War II and the postwar years remained similar to that of the U.S. army, but there were some confusing differences in terminology. Though the artillery branch of the British army was of sufficient strength and importance to be considered a corps, it retained the traditional name of royal regiment of artillery. The basic tactical unit of the British artillery was the field regiment, normally commanded by a lieutenant colonel and composed of three batteries equipped with 25-pounders or their equivalent. The field regiment corresponded to the U.S. battalion in terms of its tactical role, but in terms of size the British battery was more nearly the equivalent of the U.S. battalion. Going one step farther down the scale, the British troop, typically a 4-gun unit within the battery organization, corresponded in size to a U.S. 4-gun battery.

3. Soviet Union.—Artillery, often referred to by Soviet leaders as "the god of war," has always played a leading role in the Soviet army. The artillery arm and its services made up from 25% to 35% of all personnel in the Soviet army during World War II and the years that followed. It included conventional field artillery, antitank and antiaircraft guns, heavy mortars, rocket launchers and guided missiles, but not self-propelled artillery, which was assigned to the armoured forces. An average Soviet artillery division in World War II, consisted of from 18 to 24 firing batteries, but this number was reduced in postwar years. Each artillery battalion was made up of three or four batteries, with either two or four pieces to each battery. Battalions of the same type were organized into brigades, thus forming howitzer brigades, mortar brigades, rocket launcher brigades, etc.

A still larger grouping, the artillery corps, consisted of two or three artillery divisions and two or three small antiaircraft divisions as well as several special purpose artillery brigades and regiments. The artillery corps facilitated the massing of great numbers of artillery pieces for a major offensive. This high degree of centralized control developed early in World War II following disastrous losses, and was made necessary in part by the shortage of trained artillery officers. The high command withdrew a large share of the artillery from its rifle divisions and placed it in artillery divisions under the over-all direction of army headquarters.

In the period following World War II the Soviet army relaxed its highly centralized control of artillery to some extent. It returned a substantial amount of artillery firepower to the rifle divisions. Each regiment in a rifle division was equipped with 76-mm. self-propelled guns, 57-mm. antitank guns and large mortars such as the 120-mm. mortar. In addition, the division had two artillery regiments, one equipped chiefly with 76-mm. guns or the newer 85-mm. guns, and the other with 122-mm. howitzers and huge mortars. The division commander exercised operational control over both artillery regiments. The Soviet tank division possessed a great deal of mobile firepower in the form of 152-mm. self-propelled guns plus a regiment of huge mortars, a regiment of truck-mounted rocket launchers and a battalion of howitzers.

(H. C. T.)

VIII. TECHNIQUE

1. Occupation of a Position.—The actual process of coming into action may be described in a few words. The location for each gun is established in accordance with the mission, the expected direction of fire and the restrictions of the terrain. Each gun is brought to its position, unlimbered and laid parallel, and enough ammunition to fulfill expected requirements is unloaded. Only those items required for the conduct of fire are kept at the firing battery position, the balance being located in sheltered positions nearby or in some rear area. The noncombatant vehicles form the "second line of wagons."

2. Choice of a Position.—The nature of the position to be occupied depends primarily upon the task which is to be carried out. Although "open" positions may have to be occupied on occasions, they are generally to be avoided since guns are quickly silenced in modern war if they come into action in full view of the observing posts of the hostile artillery. As a rule, therefore, artillery uses positions concealed from view behind a ridge or other cover, the elevation and direction necessary to hit the target being signaled by an observer who may be either on the ground or in the air. The choice of the position varies to some extent with the nature of the equipment; for instance, an elevated position is better adapted than a low one for high-velocity guns because of their flat trajectory.

Other factors which have to be considered are: (1) the desirability of a field of fire immediately in front of the guns for shooting at hostile tanks; (2) concealment from air observation; (3) avoidance of ground in which pockets of gas might lie; and (4) approaches for ammunition supply. It is usually possible, however, to satisfy only the more important requirements in each particular situation. Cover from hostile fire, as distinct from observation,

cannot often be obtained from the configuration of the ground, because, if a gun can shoot over a covering feature, the hostile shells can also clear it. Most of the lighter types of artillery are therefore provided with shields which, with the armoured ammunition wagons (caissons), afford some measure of protection to the guns and detachments. Guns are usually brought into action about 20 to 25 yd. apart, this interval being considered sufficient to minimize the damage which may be done by hostile shellfire.

3. Ranging.—This process serves to determine the elevation at which a gun will hit the target, or, more correctly, the elevation at which the greatest possible number of shells will fall on the target. This elevation is not necessarily that due to the map range, since it is affected by the temperature, height of barometer, strength of the propellant, degree of wear of the gun and other factors. When a number of shells are fired from a gun which is pointed at a given elevation, they do not fall in the same place, but are distributed over a space which, at medium ranges, may be 100 yd. or more in depth. The centre of this space is termed the "mean point of impact." The first step in ranging is to determine, by observation of the fall of the shells, two elevations, usually 400 yd. apart, at the higher of which the shells will fall beyond the target and at the lower of which they will fall short. This bracket is split successively by applying corrections in range equal to one-half of the bracket in the direction of the target until the bracket is reduced to 100 yd., at which time the bracket is split by a 50-yd. correction and fire for effect begun. Ranging for line, *i.e.*, for lateral direction, is carried out in the same way, and is generally simultaneous with ranging for elevation. When air bursts are desired it is also necessary to determine by observation the fuze time which will produce bursts at the most effective height above the ground; however, through the use of radar-activated VT fuzes, the optimum height of burst is obtained automatically.

4. Ranging by Map or Survey Methods.—It is possible to open effective fire by surprise without preliminary ranging, if the range and line can be obtained by measurement from accurate large-scale maps or, in the absence of such maps, by "fixing" the positions of guns and targets by survey methods. For such predicted shooting certain meteorological and other information is necessary to determine the corrections which must be applied to the true range and line. Special sections in corps and division keep the batteries informed as to atmospheric conditions. The guns must be carefully calibrated, a process which consists in determining the error due to wear at a known range. Survey methods cannot generally be used in very mobile operations because of the time required to carry out the necessary preliminary work.

5. Sound, Flash and Radar Ranging.—These techniques perform dual functions: determining the ranging of friendly guns and locating enemy guns. They are effected in one of three ways: by observing and correlating the moment at which the sound of the burst of a shell or report of a gun reaches each of a chain of recording instruments; by performing an intersection on the observed flash; or by following the path of the shell on a radar screen and extrapolating to its origin or terminus.

6. Laying.—Elevation may be defined as the vertical inclination of the gun, direction as the horizontal inclination to the right or left, necessary to direct the path of the projectile to the object aimed at. In order to lay the gun in the line of sight (*i.e.*, the line joining the sights and the point at which aimed) the gun has to be traversed right or left so as to point in the proper direction, and also adjusted in the vertical plane. The simplest form of laying is called the direct method, which is employed if the point at which aimed is the target and can be seen by the layer who can then merely look over or through the sights. But the point laid on is rarely the target itself. In war, the target, even if visible, is often indistinct, but in most cases it cannot be seen at all from the gun position. An aiming point, a conspicuous point quite apart and distant from the target, has then to be employed (indirect method). When the guns are behind cover and no natural aiming point can be seen, an artificial aiming point is often made by placing a line of aiming posts in the ground. A method which is now obsolete was provided by the paralleloscope, which was a mirror set a few feet from the gun. When this device was used, the layer kept the gun in the correct line of fire by laying upon the reflection of the sights in the mirror. Finding the line in the case of indirect laying involves the calculation of the angle at which the guns must be laid in order that, when the sights are directed upon the aiming point, the shell will strike the target. When a gun is laid for elevation by the indirect method, two angles to the horizontal plane have to be allowed for, viz., that due to range and that due to the difference in level between the gun and the target. The latter is called the angle of site. When the target is above the level of the gun, the angle of site has to be added to the elevation due to the range; when the target is below the level of the gun the angle of site has to be deducted. In all cases the actual elevation of the gun to enable the shell to strike the target is a purely mechanical adjustment, the gun being moved to the required angle with the aid of an elevation indicator or a clinometer. Frequently the battery commander directs the guns from a point at some distance, communication being maintained with radio or by field telephone. Instruments of precision and careful calculation are, of course, required to fight a battery in this manner, many allowances having to be made for the differences in height, distances and angle between the position of the battery commander and that of the guns. (*See* RANGE FINDERS; SIGHTS, GUN.)

7. Fire.—Three methods of fire for effect are used within the battery. These are:

Gunfire, in which the guns fire independently at any rate which may be ordered;
Battery fire, in which the guns fire in succession throughout the battery;
Salvo fire, in which the guns are fired simultaneously on the order of the gun position officer.

The application of fire by batteries acting in combination is dealt with in the section on *Tactics,* below.

8. Use of Various Types of Ammunition.—High-explosive shells are fired by all guns and howitzers against troops in the open, for offensive and protective covering fire, for antiaircraft fire and for general harassing purposes. The explosive charge within the shell causes the shell case to burst and fill the air with small, high-velocity, jagged fragments. Armour-piercing shell is used to breach the armour of tanks and is composed of a core of high-carbon alloy steel or tungsten carbide, with a shock-spreading cap of hard steel. Smoke shells are used for screening effect, to mask hostile fire, to deny observation to the enemy and to produce casualties from the burning particles. Shells with smoke fillers of various colours are used to signal and to mark targets for attack by other means. Illuminating shells are used to provide light on the battlefield to disclose enemy locations and night movements and to facilitate observation and adjustment of fire. Other artillery shells may be used to spread toxic or nontoxic gases or propaganda leaflets.

One of the most famous secret weapons of World War II was the U.S.-developed proximity or VT fuze which added greatly to the effectiveness of both ground and antiaircraft artillery. This fuze contains a tiny electronic device which sends and receives impulses as it spirals through the air in the nose of a shell. As the shell approaches its target, the electronic device automatically explodes the projectile at a predetermined height over it, producing perfect air bursts 20 or 30 ft. above the ground. The VT fuze put an end to the inaccuracies associated with the mathematically calculated and manually set time fuzes in use during the greater part of the war. Shells that explode at the ideal height, round for round, are tremendously more effective than those that burst too far above the target or too close to it, particularly when the maximum burst is diminished if the nose burrows into the ground before the explosion occurs.

The VT fuze, which was put into combat use in the winter of 1944, was also adapted for antiaircraft artillery and proved its mettle as a dependable destroyer of bomber and fighter aircraft. It was responsible for blasting to bits in mid-air hundreds of the German buzz bombs that were hurled against Great Britain and the Allied supply concentrations. (For a description of various types of projectiles *see* AMMUNITION, ARTILLERY.)

IX. TACTICS

In modern war it is found that infantry troops, in face of opposition, are immobilized and driven to seek cover as soon as they get within the zone of the enemy's aimed rifle and machine-gun fire. Attacking troops can continue to advance (and without advancing no decision can be gained) only by enlisting the aid of an arm which is capable of keeping down the enemy's fire while itself remaining sufficiently immune by reason of the distance from which it can operate, or by armoured protection as in the case of tanks. Artillery affords the principal means of dominating the enemy's fire. The advent of tanks, however, profoundly affected the role of position artillery in battle. Tanks are capable of relieving the artillery of various forms of support required by infantry and cavalry, but tanks themselves require artillery support if they are not to suffer heavy casualties. Further, the relative position of tanks and artillery became confused since some of the most modern types of armoured artillery on self-propelled carriages are themselves tanks under a different name.

Developments during and after World War II greatly increased the range, accuracy, firepower and mobility of artillery. A further important advance was in methods of survey. There are certain limitations to the full development of the power of artillery, the most serious of which is perhaps the difficulty of including in mobile formations sufficient artillery to break down modern defenses, and of supplying it with ammunition. Good signal communications between artillery commanders, their guns and the troops they are supporting are of vital importance.

1. Application of Fire.—The principles of surprise, concentration and economy of force (*i.e.*, economizing strength while compelling dissipation of that of the enemy) are generally held to be of special importance in the application of artillery fire. To obtain surprise it is necessary first to conceal the concentration of the guns and the occupation of positions. In order to evade detection by hostile aircraft, large movements of artillery are generally carried out at night. Should they be carried out by day, skillful use of cover is necessary to screen movement from observers on the ground.

Once the guns are in position, care has to be taken not to disclose their position by firing prematurely and, to this end, the survey methods of working out lines of fire and ranges, already alluded to, are of particular value, since the warning which used to be given by preliminary registration can be eliminated by their adoption in certain circumstances. There is, further, considerable scope for exploiting the value of surprise after the presence of the guns has been disclosed by the opening of fire. Stereotyped systems of shooting should be avoided and damage and casualties increased by bringing fire to bear on the enemy at unexpected times and places and in unexpected ways.

Concentration of effort is as essential in the employment of artillery as in the case of any other arm. The maximum amount of fire must be directed upon the targets which are of greatest importance, and bombardments should be intense and short rather than weak and prolonged. The best means of securing concentration is to centralize command, and it is thus a general principle that control should be vested in the highest commander who can exercise it effectively in any given situation. For effective control, a commander must be in communication with the guns and in touch with the ever-changing situation of the troops he is supporting. When operations are of a deliberate character, intercommunication is comparatively easy to maintain and information is fuller. Control may then be exercised from divisional or even corps headquarters. In very mobile operations, however, artillery brigade or battery commanders will often have to act upon their own initiative, subject to broad instructions from their superior commander.

The maintenance of the principle of concentration involves a strict observance of the allied principle of economy of force. Artillery should be allotted economically. However, artillery never is retained tactically in any reserve status. The various types should be employed against the targets they are designed to engage. Thus, it would be wrong to use a powerful weapon for a task which could be equally well performed by a less powerful one, the life of which is longer and its ammunition more easily supplied. Fire should never be opened without a definite object, and the expenditure of ammunition should be proportionate to the tactical importance of the task. Economy is further obtained by accuracy of fire, but occasions arise when some degree of accuracy may have to be sacrificed to save time and to ensure surprise.

2. Observation.—Whenever possible, artillery fire is directed by observation which may be carried out from the ground or from the air. Ground observation is most suitable for shooting on targets on the immediate front of friendly troops, and observation posts are selected, whenever possible, so that they may overlook the foremost elements of the troops who are being supported as well as the areas in which targets are to be engaged. Observation from aircraft is largely used for counterbattery work, for fire on distant targets and for dealing with vulnerable and fleeting targets which cannot be seen from the ground. In modern armies the requirements of the artillery in air observation are met by army aircraft and the co-operation of the air forces. Aerial photographs of enemy positions and rear organization are of great value in the discovery and selection of targets. Balloons were widely used in World War I for purposes of observation, but they were handicapped by their vulnerability and the distance from the enemy at which they must operate. The helicopter supplanted and far surpassed the balloon as the aerial observer for artillery, particularly when targets are located at relatively close ranges. Helicopters can take off and land vertically and do not require the facilities of prepared airfields. They can maintain a static position in the air while at the same time they possess considerable speed and complete flexibility insofar as directional flight is concerned.

3. Co-operation With Other Arms.—Since the role of the artillery is to support the other arms, its action is governed by their requirements. The question of co-operation with the other arms is, therefore, one of special importance. Artillery officers of all ranks have to keep themselves informed of the general situation and plans of commanders whom they are supporting. The best means of ensuring good co-operation is for headquarters of artillery and of units with whom they are co-operating to be in close proximity. Liaison officers are also used to aid in keeping touch and artillery patrols may be sent forward to supplement personal reconnaissance and the information furnished by artillery observers. The artillery frequently has to rely on close reconnaissance airplanes or on rockets or other special signals for information of the situation of the forward troops. However radio and wire telephonic communications between observers and artillery headquarters are usually relied upon and are the most dependable forms of transmitting information. The other arms are trained to supply constant information to the artillery as to their movements and the obstacles which they encounter; this information is essential if artillery support is to be effective. Another important aspect of co-operation lies in the co-ordination of the action of the artillery with that of the weapons of the other arms. For example, position artillery fire must be directed in such a way as best to supplement the fire of machine guns and the action of tanks.

X. ATTACK

In the attack the object of the artillery is to assist the other arms to maintain their mobility and offensive power. Its tasks may be summarized as follows: (1) artillery preparation; (2) covering fire; (3) close support; (4) counterbattery work; (5) harassing fire; and (6) co-operation in pursuit.

1. Approach March.—An army advances against the enemy covered by the advanced guards of its several columns. During the approach march some light field and possibly some medium artillery will usually be allotted to the advanced guards, in addition to tanks, whose duty it is to drive in the enemy's protective troops by bold and vigorous action. If the artillery allotted to the advanced guards proves insufficient to overcome the enemy's resistance it may be reinforced from the main bodies. If the enemy is in strength, a stage will be reached when the advanced guards will no longer be able to advance and when the main bodies or

portions of them will be deployed. A plan of attack will then be formed by the commander of the force. If the enemy has been met on the move, or found in a hastily occupied position, the situation will call for rapidity of action, since the dominant need will be to prevent him from seizing the initiative or strengthening his defenses. If, on the other hand, he is in an organized position strengthened by artificial defenses such as wire entanglements, trenches, foxholes, etc., the attack cannot be launched without deliberate and methodical arrangement and it must be supported by a strong concentration of artillery.

2. **Dispositions.**—In disposing the artillery, the governing considerations are: (1) concentration of the maximum fire to assist the decisive phases of the attack; and (2) ability to support the advance to as great a distance as possible without moving the guns. This last requirement entails siting the guns well forward, the most advanced field guns being as a rule no farther behind the leading troops than is necessary to obtain cover and to clear the heads of the infantry.

3. **Plan.**—The artillery plan comprises the scheme of fire and the arrangements for command, control, communications and movement of artillery in support of the advance. A commander will often have to decide whether it is important or not to use the full power of his artillery in his attack. To develop its full strength the artillery may often require more time for preliminaries than the other arms, and a plan of attack may suit it which does not best suit the other arms. In such a case a commander will generally treat his artillery as the predominant arm if the enemy's defenses are strong.

Artillery preparation consists of the bombardment of the enemy's defenses before the attack is launched, its objects being to inflict loss and damage, to cut wire obstacles—if tanks are lacking—and to undermine morale. If the enemy's positions are not strong or if tanks are available, artillery preparation may be dispensed with and surprise ensured thereby. If it is undertaken it should be as short and heavy as possible.

Covering fire may take the form of a barrage (*i.e.*, a belt of fire) moving ahead of the assaulting troops; of concentrations upon successive localities; of smoke screens; or a combination of any or all of these forms of fire. A barrage has some measure of destructive and neutralizing effect on all troops on the ground over which it passes. It is the simplest method of giving support when the enemy's positions cannot be located with accuracy—and in the two world wars this was the normal state of affairs, because of the difficulty of seeing machine-gun posts, etc. In face of strong opposition, reliance would have to be placed upon considerable reinforcements of army artillery units or upon tanks to supplement the action of the artillery. As a rule, in providing covering fire, light artillery is used to shoot nearest to the assaulting troops, who are trained to move as close as possible to the bursts, and medium and heavy artillery are used to give depth to the fire and to shoot on more distant targets. Ordinarily, covering fire is arranged in its early stages according to a timetable based on the expected rate of advance of the troops or upon the attainment of predetermined phase lines or objectives. Subsequent support is given by observed fire from guns advanced, if necessary, during the fight.

Smoke shells are fired by artillery in conjunction with other types of ammunition or alone. The principal use of smoke is to furnish concealment to attacking troops in order to enable them to move unobserved for the purpose of effecting surprise. By its use an attack can get to close quarters without being seen and smoke clouds can often be so disposed as to enable the assault to be launched from an unexpected direction. Smoke screens may also be used to conceal the movement of reserves. Smoke is also of great value in reducing casualties among the assaulting troops by preventing the enemy's fire from being aimed or observed, and it should therefore be the object of the attacker to use it in such a way as to blind artillery observation posts and to mask machine-gun positions, strongly defended localities and antitank weapons. Smoke screens may also be put down by artillery to protect open flanks, or to prolong a front of attack and so induce the enemy to disperse his fire.

The tendency of an enemy, when a smoke cloud is put down, is to pour a heavy fire into it and this fact has to be borne in mind in evolving plans for its employment. The actual production of a smoke screen requires great skill and the wind and weather have to be carefully considered. If smoke is fired indiscriminately it may interfere seriously with observation from both ground and the air, with reconnaissance during battle, with signaling or with operations of troops on the flanks. (*See* SMOKE: IN WARFARE.)

4. **Close Support.**—The prearranged covering fire may not be sufficient to overcome all resistance to the advance and leading units therefore have to be accompanied by some artillery to obviate the delay which would be entailed in signaling to guns at a distance. So much is generally admitted; but the nature, command and organization of the accompanying artillery are matters on which opinions differ. Moreover, the infantry are not satisfied with guns of accompaniment, but demand a weapon of their own in the actual firing line to deal with tanks. (*See* INFANTRY.)

5. **Counterbattery Work** comprises the location, neutralization and, when possible, destruction of the enemy's artillery. The problem of dealing with the hostile guns is given much greater attention in all armies than was the case before World War I. It enters into operations of every kind and in varying degrees lies within the sphere of responsibility of every artillery commander. Special counterbattery staffs are generally provided at corps headquarters. The chief sources of information as to the enemy's artillery are: (1) observers in aircraft; and (2) flash-spotting and sound-ranging units on the ground. In addition, artillery and infantry observers are trained to send back information. A portion of the attacker's medium and heavy artillery is usually given the task of engaging the hostile guns before and during an action with the object of keeping down their fire and so facilitating the advance of the assaulting troops.

6. **Harassing Fire.**—The objects of harassing fire are to wear down the enemy's fighting spirit, to inflict casualties and damage upon him, to prevent movements of reinforcements and ammunition and generally hinder the conduct of the defense. Harassing fire has to be reduced to a minimum in mobile war because of the small quantities of ammunition which are available; in deliberate operations or static warfare there is great scope for its development.

7. **Pursuit.**—During an advance, artillery is pushed forward to support the infantry and to assist them in pressing the enemy, batteries usually being moved alternately within divisions to ensure that the covering fire will be continuous. But to obtain decisive results in a pursuit it is necessary to launch against the enemy a special pursuing force, composed of mobile troops. Mechanized artillery is of special value with such a force, and it should be handled with the greatest boldness, risk being accepted which would not be justifiable at other times. (*See* ARMOURED FORCES.)

XI. DEFENSE

In defense the artillery assists in the protection of the other arms and co-operates with them in repelling the enemy's assaults. Its tasks may be summarized as follows: (1) counterpreparation; (2) fire to repel assaults; (3) antitank defense; (4) counterbattery work; and (5) harassing fire.

1. **Dispositions.**—In defense the artillery has to be sited in such a way that it will be able to bring the full weight of its fire to bear in front of the line of infantry defenses on which the commander intends to stop the enemy. In mobile war the infantry defensive position will generally consist of a chain of defended localities, and it will usually be in front of this line that the artillery will be required to shoot in order to break up an assault. In more deliberate operations, however, time and resources may permit of the defensive position's being more highly organized. It may then consist of a lightly held forward zone, intended to absorb the first shock of a heavy attack, and a strongly held main zone in which the battle is to be fought out. In this type of defense the bulk of the artillery has to be sited farther back with the object of bringing the main weight of its fire to bear in front of the main zone, a

small proportion only of guns being allotted to support the troops in the forward zone.

The bulk of the guns are not sited in such advanced positions in defense as in attack for two reasons: (1) that they may not be easily neutralized by the attackers' artillery; and (2) that they may not be overrun in the first rush of an assault. A proportion of the guns must be in forward positions, however, for the purpose of engaging the enemy's artillery and rear communications and of hindering arrangements for an attack. The fulfillment of these requirements results in the defender's artillery being distributed in depth. An important factor which must also be considered in disposing the artillery is the problem of antitank defense. This is discussed below. An essential requirement of defensive positions to be occupied by infantry, besides facilities for siting the guns, is suitability for artillery observation. It is always desirable that there should be some rising ground from which observation can be carried out, and such localities should be so far behind the foremost defenses that they will not be captured, and the eyes of the defense blinded, by a minor penetration by the enemy.

2. Plan.—The artillery plan of defense comprises, besides the arrangements for dispositions, the scheme of defensive fire and the policy which is to govern counterbattery action. Surprise is as important in defense as in attack and it is therefore important that the fire plan should not be disclosed prematurely. A favourite device is to keep as many as possible of the defending guns silent until an attack develops and then to engage the enemy with an unexpectedly heavy fire. In order to conceal the battle positions of the defending artillery, guns which are required to be active often shoot from temporary positions which they vacate before the enemy's attack is launched. It is important to make arrangements to concentrate as much as possible of the available artillery fire on any particular portion of the front which may be attacked by the enemy and to make all possible preparations to support counterattacks. Smoke should be used with caution in defense since it is liable to obscure the view of the defenders and so to hamper their fire.

Counterpreparation is the term applied to fire which is delivered with the object of breaking up an attack before it can be launched. It is directed against probable forming-up places and forward communications in order to disorganize the enemy's troops when they are suspected of being about to assault. A plan of predicted fire is usually arranged as soon as a defensive position is occupied but, if the enemy's troops can be seen and signal communications can be maintained, it is more effective to shoot with direct observation.

3. Repulse of Assaults.—Once an attack is launched it becomes the aim of the artillery to direct fire on the assaulting troops and reserves. It is desirable that, as in the case of counterpreparation, such fire should be controlled by observation, but this is not often practicable. Attacks may be launched under cover of smoke or in the half-light of dawn, and signal communications may be cut by hostile fire; even when other conditions are favourable, observation will be rendered impossible when there is such a force of artillery that observers are unable to distinguish the shells of their own batteries. It is therefore a rule to detail targets to be engaged by all batteries with predicted fire. Such targets will generally be the most probable lines of approach for the enemy and other vulnerable portions of the front, and the fire of the guns must be carefully co-ordinated with that of the infantry weapons, especially with that of machine guns.

4. Antitank Defense.—A considerable share of the responsibility for antitank defense falls upon the artillery. The antitank weapons of the infantry are generally reinforced in the forward defenses by some light or field pieces which are sited in concealed positions from which they can deliver a sudden fire at short range. A serious objection, however, to the employment of artillery in this task is that guns sited in forward and exposed positions are of little use for general purposes of defense. A second line of defense is formed by the main force of the artillery, all battery positions being chosen as far as possible so as to provide a field of fire against tanks. In addition, some guns have to be disposed for the protection of headquarters and other important points in the rear.

5. Counterbattery.—Attack of enemy batteries is generally carried out by the defenders with the object of weakening the hostile artillery before an assault is launched. Once the attack develops, however, it may be preferable to direct the full power of the defending artillery for a time upon the assaulting troops.

6. Harassing Fire.—In a defensive action of a temporary nature this form of fire will not generally be developed because of the necessity for economizing ammunition. When resources permit, however, an enemy's offensive preparations may be considerably hampered by a well-devised scheme of harassing fire.

7. Withdrawal.—When a force is retiring in the face of an enemy, mobile artillery is of particular value for covering the withdrawal of the other troops. Thus, rear guards usually contain a large proportion of guns. Enemy columns should be engaged at long ranges with the object of forcing them to halt and deploy as frequently as possible. Command of the artillery will generally have to be decentralized to infantry brigades or corresponding units in this form of operation, and batteries should retire alternately in order that continuous support may be provided.

XII. ANTIAIRCRAFT DEFENSE

The use of military airplanes in World War I forced artillery to take on a new dimension. Instead of being confined to lateral firing from one point on the earth's surface to another, it now had to reach skyward to attack enemy bombers. New gun carriages had to be designed to point guns straight up, or at least at very high angles of elevation, and new techniques had to be devised for gauging the height and speed of enemy planes and for computing the proper aiming point for the antiaircraft weapons. For control of AA fire, the height finder was the counterpart of the range finder employed by field artillery, but it was only one of many ingenious devices needed to cope with the problem of attacking fast-moving, high-flying planes capable of taking evasive action in three dimensions. Of great importance were time fuzes that exploded shells after a predetermined time of flight and, in World War II, the remarkable VT fuzes that automatically caused shells to burst when they came within range of a target. The location and tracking of targets by visual and aural means were replaced during World War II by radar, which was more accurate and was not limited to short distances, clear weather and daylight. (See *Antiaircraft Artillery* above. *See* also AIR POWER.)

In early prediction equipment it was necessary to observe the target from at least two locations and compute firing data by plotting from curves on drums and quadrants. The data were then transmitted by telephone to the guns and applied manually. Later a continuous flow of data was computed mechanically through action of the sighting device upon carefully prepared and correlated cams and variable-speed devices. The computers in use during the 1950s took the position and course of the target directly from the radar, computed its predicted position electronically and transmitted the firing data directly to the guns in the form of electrical signals which elevated, traversed and set fuze data on the guns automatically.

Powerful antiaircraft guns normally were concentrated in fixed positions near cities, ports or supply bases. When effectively used, they were able to make the attackers pay a heavy price for their bombing raids. Troops in advanced bases were accompanied by lighter mobile AA weapons while columns on the march defended themselves with still lighter weapons such as the famous Bofors 40-mm. gun. Close co-ordination between AA batteries and the air force was essential to avoid firing on friendly planes.

During the 1950s new rocket weapons entered the picture. The most effective of these were the guided missiles, so different from conventional weapons that they constituted a revolutionary new category of AA matériel. After being fired from ground launchers, the missiles were subject to control from the ground by intricate electronic devices and could be guided toward enemy planes even though the planes took evasive action. They could attain supersonic speed and thus prove more than a match for jet planes. In the United States, batteries of Nike missiles for AA defense were placed near scores of important target areas and troops were

specially trained for their operation. The first type of Nike missile, known as Nike-Ajax, was soon supplemented, and to some extent replaced, beginning in 1958, with Nike-Hercules, a longer ranging missile capable of carrying a nuclear warhead.

ART INSTITUTE OF CHICAGO. The Art institute was incorporated on May 14, 1879, for the "founding and maintenance of a school of art and design, the formation and exhibition of objects of art, and the cultivation and extension of the arts of design by any appropriate means." It is financed primarily by voluntary gifts and bequests. The building on Michigan avenue at Adams street was designed by Shepley, Rutan and Coolidge, and houses more than 150 galleries, classrooms, studios and offices, the Ryerson art library, the Burnham architectural library, Fullerton hall, the Goodman Memorial theatre and a restaurant. The paintings represent Italian, Netherlandish, Flemish, French, Spanish, German, British and U.S. schools, notably from the Bartlett, Coburn, Eddy, Kimball, Palmer, Ryerson, Winterbotham and Worcester collections. Late 19th- and early 20th-century French painting collections are especially important. The department of prints and drawings includes drawings, engravings, etchings, lithographs and a library of graphic arts. The Japanese print collection is one of the largest in the world. The Buckingham collection of ancient Chinese bronzes and the Tyson collection of Chinese ceramics are outstanding. There are also collections of sculpture, primitive art, historic (European and American) furniture, ceramics, silver, textiles and the Thorne Miniature rooms. The school is the largest art school in the country. All phases of art, including the theatre, are taught from children's classes to the master's degree level. Two bronze lions by Edward Kemeys at the entrance are often used as symbols of Chicago. Lorado Taft's "Fountain of the Great Lakes" is at the south terrace. Museum educational work includes lectures, sketch classes and gallery tours.

(R. P. T.)

ARTIODACTYL, any member of the order of ungulate mammals (Artiodactyla) comprising the pigs, camels, deer, goats, sheep, cattle, antelopes and other living and extinct forms.

General Characteristics.—In artiodactyls, the main axis of the limb passes between the third and fourth toes. Each of these toes is well developed and more or less equal in size. The second and fifth, or outer toes, are considerably smaller or entirely absent. The first toe is never present in living forms but is preserved in the forefoot of some of the earliest fossil swinelike species. The ordinal name Artiodactyla, meaning even-toed, is an allusion to the fact that all living members of the group, except peccaries with three functional toes on the hind foot, have either two or four toes on each forefoot and hind foot. The name Paraxonia, also applied to the group, refers to the disposition of the third and fourth digits to each side, respectively, of the main axis of the whole foot. In the so-called odd-toed ungulates, or Perissodactyla, the main axis of each foot passes through the middle, not to one side, of the third toe, which is always conspicuously larger than any of the other toes. (*See* Perissodactyl.)

The bodies of artiodactyls are supported in walking on the two middle toes of each foot except in the hippopotamus, where all four toes of each foot reach the ground. The toes of all recent artiodactyls, except camels, are encased in hoofs. In camels, the two middle toes are contained in a broad pad that forms the sole of the foot. The hoofs of the extinct North American *Agriochoerus* are clawlike; the animal may have been arboreal. Along with the modification of the foot bones, the ulna of the front leg in living forms is greatly reduced and more or less joined to the radius and, with the exception of chevrotains, the humerus is without an entepicondylar foramen. In the hind leg the fibula is vestigial and the third trochanter of the femur is absent.

Most artiodactyls, particularly the males, possess one, or rarely two paired frontal appendages in the form of horns or antlers; an unpaired third horn was present in some extinct deer. The muzzle of artiodactyls is long, the brain case small, the nasal bones not expanded behind; in most artiodactyls, the socket for the eye is completely encircled by bone. A clavicle is absent. There

FIG. 1.—(LEFT) LEFT HIND FOOT OF PIG SHOWING TWO CENTRAL TOES, CHARACTERISTIC OF ARTIODACTYLA, COMPARED WITH (RIGHT) LEFT HIND FOOT OF TAPIR SHOWING THE ODD-TOED CONDITION CHARACTERISTIC OF PERISSODACTYLA. (ROMAN NUMERALS INDICATE THE NUMBER OF DIGITS THAT PERSIST FROM THE EARLIER FIVE-TOED HOOFED MAMMALS.)

are seven neck vertebrae, even in the giraffe. The number of thoracic vertebrae varies from 12 in the camel to 15 or 16 in the hippopotamus, but the combined number of thoracic and lumbar vertebrae never exceeds 19 in living artiodactyls. There are five sacral vertebrae and a variable number of caudal vertebrae.

The number of teeth in all artiodactyls is derived from the basic formula of three incisors on each side of the upper and lower jaw, one canine, four premolars and three molars, a total of 44. The upper incisors and first premolar are absent in most ruminants. The upper canine may be developed into a long tusk or may be absent. The lower canine is well developed in swine and hippopotami but is reduced or incisiform in ruminants. Artiodactyl molars are of several types. Brachydont molars are low-crowned. Hypsodont molars are high-crowned, but the bases of the enamel folds that define the cusps are not visible from the grinding surface. The three or four main cusps of brachydont molars are usually conelike, or bunodont. The main cusps of hypsodont molars are generally crescent-shaped, or selenodont. In molar crowns of intermediate height, the cusps of one side may be bunodont while those of the opposite side are selenodont. This type is called bunoselenodont. The structure of the molars as well as that of the limb bones are of the greatest importance in the classification of the artiodactyls.

The stomach of living ruminant artiodactyls is divided into three or four chambers. In swine and hippopotami the stomach is less specialized and not adapted for rumination. A caecum and a gall bladder are usually present. The uterus is bicornuate and, except in the hippopotami, the testes descend into a scrotum.

Artiodactyls are well provided with integumentary glands. Mammary glands are always present in the inguinal region and sometimes are also present in the abdominal region, as in swine. Odoriferous glands are distributed on various parts of the body

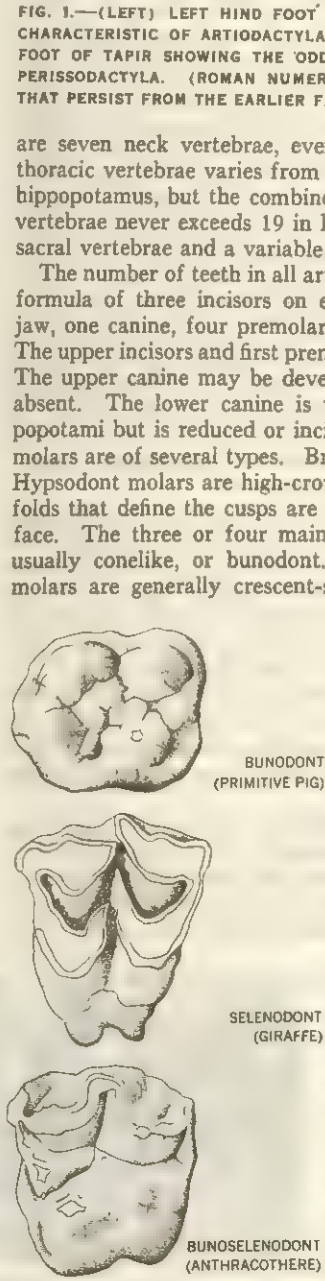

FIG. 2.—GRINDING TEETH OF ARTIODACTYLS (SURFACE VIEW)

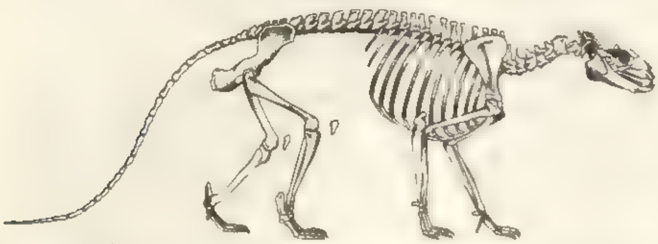
including the inguinal and abdominal regions, middle of the back, front of the eye, forehead, feet and tail.

Artiodactyls have a keen sense of smell. Their hearing is also acute, but their sight is less developed. Most artiodactyls are nocturnal and therefore depend on smell for selecting food and distinguishing between their own and other kinds of animals. Diurnal, plains-dwelling ungulates also depend more on detection of wind-borne smells and sounds for survival than they do on vision. The mating instinct is also stimulated and guided by smell.



FROM P. GRASSÉ, "TRAITÉ DE ZOOLOGIE"

FIG. 3.—SKELETON OF AN EXTINCT, PROBABLY ARBOREAL ARTIODACTYL, AGRIOCHOERUS LATIFRONS

Artiodactyls are essentially terrestrial. Some, like goats, may climb; others, like the hippopotamus, are at home in water. No living artiodactyl, however, is arboreal or wholly aquatic and none is fossorial. All artiodactyls are herbivorous, and swine are omnivorous. Most artiodactyls are gregarious. Some species, notably certain antelopes, bison, caribou and white-lipped peccaries, form herds numbering hundreds or thousands of individuals. Generally, males and females live apart except during the breeding season. At this time the males may fight each other for domination of the females. The rut usually takes place during the fall in the temperate zones but may occur at variable times of the year in the tropical zone. Gestation usually lasts longer in the larger artiodactyls than in the smaller. One, two, rarely three young are born to most ruminants during the spring in the temperate zones and at about the beginning of the rainy season in the tropics. In domestic pigs, as many as 14 young may be born in one litter. Young ungulates can follow their mother within a few hours after birth.

Artiodactyls are native to all continents except Australia and Antarctica. Some representatives of the order, particularly swine, deer and buffalo, are also indigenous to many of the larger islands except New Guinea, New Zealand, Tasmania and those of the antarctic region. Farm and game artiodactyls, however, have been introduced by man into practically all parts of the world where suitable fodder is available. (*See* also ZOOGEOGRAPHY.)

All living and fossil Artiodactyla are arranged in three suborders, the Suiforms, Tylopoda and Ruminantia. They will be discussed below in that order. A complete classification of Artiodactyla, based upon that of G. G. Simpson, appears at the end of this article.

Suiformes.—Among living artiodactyls only pigs, peccaries and hippopotami are classified as suiformes. They are nonruminants although their stomachs are more or less subdivided into specialized sections. From one to three upper incisors are present in each jaw, the lateral incisors being the first ones to disappear. The lower incisors project forward; the canines are well developed, tusklike and generally ever-growing; the molars are bunodont; the orbit, or eye socket, is never separated from the temporal fossa; horns are absent; ulna and fibula are not greatly reduced and the middle two foot bones are never completely fused to form a cannon bone.

Typical pigs appeared in Europe between 25,000,000 and 30,000,000 years ago. *Palaeochoerus* of the end of the Oligocene may be regarded as the archetype of the true pig family Suidae. It spread into India and Africa during the Miocene before disappearing altogether. The genus *Sus*, to which most modern pigs including the domestic form belong, made its appearance in the upper Miocene of Europe and advanced into Asia, reaching India during the Pliocene. Wart hogs, including the living genus Phacochoerus, arose in Africa about the end of the Pliocene. Other surviving members of the pig family are the Asiatic pygmy hog *Porcula*, the East Indian babirussa (*Babirussa*), the African river hog (*Potamochoerus*) and the forest hog (*Hylochoerus*). (*See* also PIG; BOAR.)

True peccaries, family Tayassuidae, differentiated in Europe about the same time, if not earlier, than true pigs. One branch of peccaries, beginning with *Perchoerus*, reached the western hemisphere and survived to this day. The old world branch of peccaries, typified by the Oligocene genus *Doliochoerus*, spread into Asia before it disappeared altogether during the Pliocene some 8,000,000 or 9,000,000 years ago. Living peccaries are now represented by two species in tropical America, the collared peccary (*Tayassu tajacu*) and the larger white-lipped peccary (*Tayassu pecari*). (*See* also PECCARY.)

The family Hippopotamidae is made up of three genera, of which only one, *Hexaprotodon*, is extinct. This genus appeared about 20,000,000 years ago at the end of the Miocene in the Mediterranean region and in India and persisted until the Pleistocene. One of the living forms, *Hippopotamus amphibius*, now confined to Africa south of the Sahara, had already advanced well into Africa and Europe during the upper Pliocene and reached England in the Pleistocene. The third member of the family is the west African pygmy hippopotamus, *Choeropsis liberiensis*. (*See* also HIPPOPOTAMUS.)

The most ancient of the suiformes are the extinct paleodonts. These piglike animals lived in Europe and North America some 30,000,000 to 60,000,000 years ago during the Eocene and Oligocene. Some of the oldest of these fossils belong to the family Dichobunidae. They were rabbitlike in size, possessed 44 teeth, small incisors and canines and rather simple molars. Another family, the Entelodontidae, widely distributed in Europe and North America during the Oligocene, included specialized forms ranging in size from pigs to hippopotami. The unique characteristic of entelodonts is the presence of a large process extending from each cheekbone and two similar ones projecting from each side of the lower jaw.

Ancodonts are piglike suiformes with 44 teeth, the upper molars selenodont, the lower bunoselenodont. They lived about 20,000,000 to 50,000,000 years ago in Asia, Africa and North America. Of the two known families, the Anthracotheriidae is the more primitive. Anthracotheres were generally large, the skull of one being five feet long. Their size, heavy skeleton, well-developed four toes on each foot and a rudimentary fifth toe on the forefoot in some species, certain characters and aquatic habits suggest a close relationship with hippopotami. The similarities, however, probably developed independently in each group. The second family of ancodonts, the Anoplotheriidae, is known only from the Middle Eocene to the Middle Oligocene of Europe.

The Oreodonts comprise a numerous but rather homogenous group of extinct suiformes with selenodont molars and four or

five toes on the forefoot. They lived in North America from 20,000,000 to 40,000,000 years ago. One of the genera, *Merycoidodon*, was about three feet long and nearly 15 in. high at the shoulder. Its limbs were primitive in structure, the radius and ulna being completely separated and the forefoot provided with four long toes and a rudimentary thumb. A related genus, *Brachycrus*, may have had a well-developed proboscis. *Agriochoerus* had five toes on the forefoot and claws instead of hoofs.

The Cainotheriidae is a family of small extinct European ungulates of uncertain affinities and unknown origin. It appeared suddenly about 40,000,000 years ago, flourished for about 10,000,000 years, then disappeared. The animals were rabbitlike in size, appearance and, probably, in habits. Their skull was marked by a sagittal crest, bony orbital ring, large tympanic bullae, a complete set of 44 teeth, five-toed limbs and with the lower leg bones separate and capable of a degree of supination exceptional among artiodactyls.

Tylopoda.—The suborder Tylopoda is composed of two families, the Camelidae, which includes modern camels and llamas, and the Xiphodontidae, made up of several extinct forms. Living camels are characterized by having: padded toes; a stomach adapted for rumination; a diaphragm with an ossification; red corpuscles of the blood ovate and not circular as in all other mammals; three upper incisors in each jaw of the young individual (only the third lateral incisor persists in the adult); canines differentiated from incisors and present in upper and lower jaws; molars selenodont and hypsodont; and auditory bullae filled with cancellous tissue. Neither the stomach nor the "hump" of camels serves as a reservoir for water.

Camels originated in North America during the upper Eocene, about 40,000,000 years ago. Like horses, they underwent most of their evolution on the North American continent before invading Asia and South America during the Pleistocene. (*See* also CAMEL; LLAMA.)

The family Xiphodontidae includes primitive selenodonts of the middle Eocene and lower Oligocene of Europe. They appear to be nearest the Camelidae but not certainly ancestral to them.

Ruminantia.—The suborder Ruminantia is the most widespread, most varied and most abundant of ungulates. It is the dominant herbivore group of the world and has been so for more than 30,000,000 years. The name Ruminantia alludes to the ruminating or cud chewing habit of the animals. Rumination is made possible by the division of the stomach into four connected chambers (three in camelids). Food when first swallowed enters the first chamber, or rumen, where it is softened by fermentation. It then passes into the second chamber, the reticulum or honeycomb bag, where further fermentation takes place. The food is then regurgitated into the mouth in the form of balls, or cuds. Each cud is thoroughly rechewed and then reswallowed. Because of its more fluid condition the rechewed mass filters through the coarser contents of the reticulum into the third and fourth chambers, where digestion continues. (*See* also RUMINANT.)

The most primitive of recent ruminants are the chevrotains of the family Tragulidae. They can be traced to the Miocene, where they seem to have evolved from a still more primitive group, possibly the Gelocidae, which dates back some 40,000,000 years to the upper Eocene. The Hypertragulidae is another family of extinct tragulidlike artiodactyls that includes such precursors of modern ruminants as *Archaeomeryx* of the upper Eocene of Mongolia and *Leptomeryx* of the North American Oligocene. The extinct Protoceratidae with their two and three pairs of long horns are the oddest of the tragulidlike ungulates. They arose during the lower Oligocene of North America and survived until the Pliocene.

The deer family, Cervidae, evolved from early traguloids during the Oligocene 30,000,000 to 40,000,000 years ago. *Eumeryx*, one of the oldest of known fossil deer, lived during the early Oligocene of China and Mongolia. The American branch of the deer family appeared some 25,000,000 to 30,000,000 years ago. (*See* also DEER.)

The Giraffidae arose about 25,000,000 years ago in the Miocene of Asia and ranged into Europe and Africa. They are closely related to both Cervidae and Bovidae but may be nearer the former. The living genera of the family are the African giraffes (genus *Giraffa*) and the okapi (genus *Okapia*). (*See* also GIRAFFE; OKAPI.)

The Antilocapridae appeared during the Miocene of North America. The horns of the pronghorn are bifurcated as in deer and the horny sheath is shed annually. The bony core of each horn, however, is permanently fixed to the skull as in true antelopes. Many forms with bizarre horns were developed but only one species, the pronghorn antelope, survives. (*See* also PRONGHORN.)

The most highly specialized and diversified family of ruminants is the Bovidae. It arose sometime during the Miocene in Asia and spread into Europe, Africa and the new world. Living representatives include the domestic cattle, goats, sheep, antelopes and all other hollow-horned ruminants. The horns of bovids are never shed. *See* also BOVIDAE.

CLASSIFICATION AND DISTRIBUTION

(*indicates extinct)

- Suborder Suiformes
  - Infraorder Palaeodonta*
    - Superfamily Dichobunoidea*
      - Family Dichobunidae* (Eocene: North America; Eocene-Oligocene: Europe).
      - Family Choeropotamidae* (Eocene: North America, Asia; Eocene-Oligocene: Europe).
      - Family Cebochoeridae* (Eocene-Oligocene: Europe).
      - Family Leptochoeridae* (Oligocene: North America).
    - Superfamily Entelodontoidea*
      - Family Entelodontidae* (Eocene-Miocene: North America; Oligocene: Europe; Eocene-Oligocene: Asia).
  - Infraorder Suina
    - Superfamily Suoidea
      - Family Suidae—pigs (Oligocene-Recent: Europe; Miocene-Recent: Africa, Asia; world-wide in domestication).
      - Family Tayassuidae—peccaries (Oligocene-Recent: North America; Pleistocene-Recent: South America; Oligocene-Miocene: Europe; Pliocene: Asia).
      - Family Hippopotamidae—hippopotami (Pliocene-Pleistocene: Asia; Pliocene-Recent: Africa; Pleistocene: Europe).
  - Infraorder Ancodonta
    - Superfamily Anthracotherioidea*
      - Family Anthracotheriidae* (Eocene-Miocene: Europe; Eocene-Pleistocene: Asia; Oligocene-Miocene: Africa, North America).
      - Family Anoplotheriidae* (Eocene-Oligocene: Europe).
    - Superfamily Cainotherioidea*
      - Family Cainotheriidae* (Eocene-Miocene: Europe).
  - Infraorder Oreodonta*
    - Superfamily Merycoidodontoidea*
      - Family Agriochoeridae* (Eocene-Miocene: North America).
      - Family Merycoidodontidae* (Eocene-Pliocene: North America).
- Suborder Tylopoda
  - Family Xiphodontidae (Eocene-Oligocene: Europe).
  - Family Camelidae—camels, llamas (Eocene-Pleistocene: North America; Pleistocene-Recent: South America, Asia, North Africa; Pleistocene: Europe).
- Suborder Ruminantia
  - Infraorder Tragulina

Superfamily Amphimerycoidea*
  Family Amphimerycidae* (Eocene-Oligocene: Europe).
Superfamily Hypertraguloidea*
  Family Hypertragulidae* (Eocene-Miocene: North America; Eocene: Asia).
  Family Protoceratidae* (Oligocene-Pliocene: North America).
Superfamily Traguloidea*
  Family Gelocidae* (Eocene-Oligocene: Europe, Asia).
  Family Tragulidae—chevrotains (Miocene-Recent: Asia; Miocene-Pliocene: Europe; Pleistocene-Recent: Africa).
Infraorder Pecora
Superfamily Cervoidea
  Family Cervidae—deer (Oligocene-Recent: Asia, Europe; Miocene-Recent: North America; Pleistocene-Recent: South America).
Superfamily Giraffoidea
  Family Lagomerycidae* (Miocene: Europe, Africa, Asia).
  Family Giraffidae—giraffe and okapi (Miocene-Pleistocene: Asia; Pliocene: Europe; Pliocene-Recent: Africa).
Superfamily Bovoidea
  Family Antilocapridae—pronghorn antelope (Miocene-Recent: North America).
  Family Bovidae—domestic cattle, sheep, goats, gazelles, buffalos, etc. (Miocene-Recent: Europe; Pliocene-Recent: Asia, Africa; Pleistocene-Recent: North America; world-wide in domestication).

ART NOUVEAU, a defined style of architecture and decoration, was launched in the 1890s by Belgian architects. Self-conscious in its reaction to the imitative styles of the 19th century, *art nouveau* was rooted partly in the determined individualism of William Morris and the arts and crafts movement (*q.v.*) in England, and partly in a valid appreciation of new materials and mechanical developments. This fusion of structural features and naturalist aesthetics resulted in a style that included the long, sensitive, flowing line of both a Paris Métro station and a rich Tiffany glass vase.

Indications of this style appeared in expositions of paintings, graphic arts, furniture and interior design as early as 1884 in Belgium and England. The first major application in architecture, however, was Henry Van de Velde's villa at Uccle, Belg., in 1894–95. The success of this building led Samuel Bing, an avant-garde Paris decorator, to invite Van de Velde to introduce his new style at the Dresden exposition of 1897. The style was first designated the *style belge* and, in 1895, the *style nouveau;* not until 1898 did it become known as *art nouveau,* a name used by Bing for the art galleries he opened in 1896. Bing was a born showman. It was largely because of his promotion of this very new style that it was adopted by the French decorators and became the fashionable, elaborate manner in which to refurbish houses, shops and restaurants. The Paris International exposition of 1900 brought the movement enthusiastic recognition.

Van de Velde was chiefly interested in the architectural application of new principles; he wrote much in their support. After 1902 his activities were concentrated in Germany where the style flourished and became known as *Jugendstil.* Van de Velde's most important structure was the Folkwang museum, Hagen, Ger. (1901).

An important contemporary of Van de Velde, the Belgian architect Victor Horta, designed numerous houses and public buildings in the style, notably the Maison du Peuple commissioned by the city of Brussels and completed in 1897. The popular fame of houses and the church of the Holy Family, by Antonio Gaudí, transformed the city of Barcelona into a capital of *art nouveau.* Removed from the mainstream of the movement, Gaudí developed an individual style which nevertheless incorporated the leading characteristics of *art nouveau.* He continued to work in this style until his death in 1926. In Paris, Hector Guimard designed

HECTOR GUIMARD'S "PROJECT FOR MÉTRO STATION," PARIS, 1900

the stations of the Métro (the underground railway), as well as other buildings and structures.

In the applied and decorative arts, *art nouveau* flourished throughout all Europe. The tendency to obliterate the straight line, to maintain a continuous flow of linear movement, is particularly evident in the interiors of restaurants like Maxim's in Paris and in the fashionable shops of the day in European capitals. Wall areas were treated as large decorative panels or were hidden by mirrors and overlaid with delicate moldings that wound around corners and onto pillars, deliberately obscuring architectural form. In addition to flower motifs, the peacock was a central decorative theme: the eyes of the tail were repeated through whole interiors and the curves of the spread fan were echoed over and over.

International expositions and fairs provided excellent showcases for the new style. Not only exposition buildings but individual rooms, furniture and art objects were designed in *art nouveau* and met with great success.

By 1902, *art nouveau* reached the apex of its international phase. The exposition that year in Turin, Italy, had for its theme the application of *art nouveau* to buildings and interiors. It was also the crossroads of the style. Most nations of Europe were represented and variants of the style were readily apparent. Belgian and French interpreters of Van de Velde's texts had elaborated them as far as possible. German, Austrian and English architects and designers gradually changed to a simpler, rectilinear manner which led to the International style. After 1902, *art nouveau* was found mostly in toiletries, jewelry, vases, wallpaper and other purely decorative products reflecting the frivolous prosperity of western Europe in the early 20th century.

In the United States, the glass and bronze designs of Louis Comfort Tiffany are the outstanding examples of the style: his glass is iridescent, his bronze flows in S-curves.

It was in execution that *art nouveau* became confused; positive values lie in its theories and principles, and in its liberating impact on the public. Despite the superficiality of its final phase, *art nouveau,* by successful application of a unified aesthetics and linear emphasis, made an important contribution to the development of modern architecture and applied arts.

ARTOIS, an ancient province of France, corresponding to the modern *département* of Pas-de-Calais, less the *arrondissements* of Boulogne and Montreuil. Its capital was Arras (*q.v.*), and other important places were St. Omer, Béthune, Aire, Hesdin, Bapaume, Lens, Lillers, St. Pol and St. Venant.

The names Artois and Arras are derived from the Atrebates, who

inhabited the district in the time of Caesar. From the 9th to the 12th century Artois belonged to the counts of Flanders. It was promised in 1180 to Philip II Augustus of France by Philip of Alsace, count of Flanders, as the dowry of his niece Isabella of Hainaut, and was conferred in 1237 as an appanage by Louis IX of France on his brother Robert, who died in 1250. His son, Robert II of Artois, was killed at the battle of Courtrai in 1302. His son Philip having predeceased him (1298), Artois was adjudged to Robert II's daughter Mahaut (Matilda) as against Philip's son Robert, who attempted to support his claim to the countship by forged titles. Banished from France (1332), Robert of Artois took refuge in England and incited King Edward III to make war upon Philip VI of France (*see* HUNDRED YEARS' WAR). His descendants, the counts of Eu (*q.v.*), continued to style themselves counts of Artois. By the marriage of Mahaut (d. 1329) with Otto IV, Artois passed to the counts of Burgundy, with whom it remained, so that the marriage of Mary, daughter of Charles the Bold, to the Austrian archduke Maximilian brought it to the house of Habsburg (*see* BURGUNDY; FRANCHE-COMTÉ). Louis XI, however, occupied portions of Artois, and the claims of Austria were contested by France until the treaty of Senlis (1493). When the Habsburg possessions were partitioned on the abdication of the emperor Charles V, Artois went to Spain with the rest of the Burgundian inheritance. At the end of the Thirty Years' War, Artois was again conquered by the French, and the conquest was ratified by Spain in the treaty of the Pyrenees (1659). The treaties of Nijmegen (1678) and Utrecht (1713) confirmed French sovereignty. The title of comte d'Artois was borne by Charles X of France before his accession.

ARTS AND CRAFTS MOVEMENT. The arts and crafts movement, which flourished in England during the 1880s and '90s, was one of many reformatory efforts protesting the social, moral and cultural confusions that accompanied the Industrial Revolution. The movement opposed the imitative architecture and shoddy, ugly, mass-produced objects of its era by reviving handicrafts and designing for them. Walter Crane, an arts and crafts leader, maintained that "the true root and basis of all Art lies in the handicrafts," reflecting the attitude of many progressives of the period, who sought in design the expression of individuality joined with expressions of fitness for use, the nature of materials and the nature of fabrication. Twentieth-century western architecture and design accept these ideals, though handicrafts no longer challenge industrialization.

Precursors to the movement in England were the Gothic Revivalists, the Pre-Raphaelites and John Ruskin, the most influential writer in English on art. In 1859 William Morris built his home from Philip Webb's designs, and two years later opened a shop where interior furnishings could be ordered. Morris and his friends endeavoured actually to practise the principles of medieval craftsmanship, not merely to imitate its forms or effects. They remastered the crafts; Webb rediscovered English vernacular building. Together Morris and Webb led the English domestic revival, which evolved into the less antiquarian arts and crafts movement. Meanwhile Japanese architecture and crafts won over artistic London at the 1862 World's fair, demonstrating principles remarkably parallel to Morris' and introducing cheerful light colourings. In the 1860s and '70s Christopher Dresser published schematic botanical ornament while Charles Locke Eastlake popularized advanced interior design to English-reading audiences. All this influenced the nascent arts and crafts.

In 1882 Arthur H. Mackmurdo (a disciple of Ruskin's), Selwyn Image and others founded the Century guild for craftsmen. In 1886 the same group began the revival of hand printing in the magazine the *Hobby Horse*. An association for encouraging cottage crafts also started in 1884 as did the Art Workers' guild, two of whose founders were W. R. Lethaby, later principal and moving spirit of London county council's Central School of Arts and Crafts, and Walter Crane, first president of the Arts and Crafts Exhibition society. This society, sheltering several groups, may be considered the focus of the movement. Ruskin and Morris were its prophets; two generations of enthusiasts had learned that art was all one—the generally accepted difference between fine arts and applied arts seemed destructive and artificial. Delegates from the Art Workers' guild approached the Royal Academy of Arts, suggesting joint exhibitions. After many meetings no agreement was reached.

The Arts and Crafts Exhibition society then was formed and held its first show in 1888. In the society's catalogue notes of 1889 Crane stated the aesthetic character of the movement ". . . plain materials and surfaces are infinitely preferable to inorganic or inappropriate ornament." Distinguished exhibitors included William De Morgan, potter; W. A. S. Benson, metal designer; and C. R. Ashbee, who founded two schools and in 1888 his own Guild of Handicraft, which lasted 20 years.

Some progressives, however, voiced dissent. Lewis F. Day, a leading designer, in 1882 said "the public . . . want machine work . . . they will not pay much heed to us." Oscar Wilde said that good machinery was graceful and that the line of strength and the line of beauty were one. John D. Sedding, designer-architect, in 1888 accepted the machine. William Morris in his socialist vein asked "what business have we with art at all unless all can share it?"; but *The Studio*, in 1893 London's new progressive art periodical, assessed the Arts and Crafts Exhibition society's fourth show as "the work of a few for the few." The same review recognized, however, a worthy protest against design as "a marketable affair, controlled by the salesman and the advertiser, and at the mercy of every passing fashion."

The '90s were full years for the arts and crafts. C. F. A. Voysey, Webb's gifted successor in architecture, became famous, though his cottage style was known earlier to enthusiasts like young Frank Lloyd Wright. Voysey's wallpapers and printed fabrics also aroused widespread admiration with their light colours and uncluttered, simplified plant patterns. Ernest Gimson's cabinetwork reached a high level. William Morris made a last contribution, his great Kelmscott press books. The arts and crafts replaced orientalia in an important shop, Liberty and Co., soon identified with the movement.

Later in the decade a group of young architects and designers, brilliantly led by C. R. Mackintosh, gave the movement new liveliness and a new centre, Glasgow. The Scots established good foreign connections, especially with Austria and Germany, and were open to the allure of ornament and the influence of aesthetic artists and writers, such as Beardsley and Wilde, which the English craft adherents rarely were.

Several craftsmen gained prominence in England between 1900–10: T. J. Cobden-Sanderson and Emery Walker founded the Doves press; Frank Brangwyn, the painter, designed distinguished rugs and furniture; Ambrose Heal translated the craftsman's style into popularly priced, well-made furniture.

In Europe during the 1890s and 1900s the influence of the arts and crafts movement expanded. A. W. Finch, the potter, in 1891 carried it to Belgium where G. Serrurier-Bovy took it up; in 1897 Finch moved to Finland, becoming an eminent arts and crafts teacher. In Holland H. P. Berlage and in Austria Otto Wagner, both leading architects, after 1895 preached gospels similar to those of the arts and crafts movement; they were followed by younger men, many leaving the *art nouveau* (*q.v.*) for this stricter, quieter style. This trend was true still later in Germany, after Peter Behrens and Richard Riemerschmid were converted. The *art nouveau* and the arts and crafts were allied to fight against historic revival styles; they were shown together in many exhibitions in Belgium, France and Germany, as well as in ten progressive periodicals that sprang up, after *The Studio's* success, from 1895 to 1898 in Germany, France and Austria. The Belgian Henry van de Velde reorganized the Weimar Academy of Art in 1900 along English craft school lines and his successor Walter Gropius kept some of this when he transformed the school into the *Bauhaus* (*q.v.*).

At East Aurora, N.Y., in 1895 Elbert Hubbard set up a deliberate evocation of William Morris' workshops. In 1897 Bostonians organized the first American Society of Arts and Crafts. In California the Greene brothers built and furnished handsome homes which showed much arts and crafts as well as Japanese influence.

Gustav Stickley's magazine, *The Craftsman*, popularized mission furniture and bungalows in the United States from 1901 to 1916. Frank Lloyd Wright at Chicago, close to the craftsmen in style, voiced realistic doubts in his repeated lecture, *The Art and Craft of the Machine*. In fact few important arts and crafts designers personally practised crafts, and many worked regularly for industry. C. R. Ashbee, visiting Chicago in 1900, was strongly impressed by Wright and later sponsored him in Europe. By 1911 Ashbee wrote that modern civilization rested on machinery, and the arts and crafts protest dissolved into craft activity, an esteemed specialty of modern design. *See* also FINE ARTS.

ART SELLING. An art sale is a sale of a work of art by an auctioneer, an art dealer or the artist himself. Art dealing may be carried out not only by dealers who have established businesses, but also by middlemen between the artist and the buyer, between the sales room and the public and between the excavator or explorer and the public. Works of art also may be sold through commission, in which case the artist comes into direct contact with the purchaser, filling a particular demand rather than supplying the general needs of the market.

History of the Art Market.—Art in the heroic, Homeric and classical ages was a craft and the artist an artisan, sometimes a wanderer moving from town to town looking for employment. In Greece, the city-state was the sole large buyer of art. Commissions were by public competition and consent, and an artist could not secure a position in the community by offering works to a general market. During the age of Alexander the Great, the growth of private wealth created a demand for art objects, but the great change that was to affect the market was that artists began to acquire some philosophical education, thus raising themselves from the level of tradesmen. Zeuxis' painting earned him a fortune, and Apelles became the confidant of Alexander himself.

During the conquests of the Roman republic in the 2nd and 1st centuries B.C. artists were often slaves and the prices of works of art were low, but toward the end of the Roman empire works of art from other countries and other ages acquired a rarity value previously confined to the cult objects of religion. The change from an agrarian society to the urban society of imperial Rome led to an exceptional rise in private fortunes, which promoted activity in the art market. Rome already possessed an art-dealing quarter near the Via Publica, and Suetonius records what was virtually an art auction conducted by the emperor Caligula himself. Most art purveyors were Greeks, Alexandrians and other middle easterners. The profession of artist continued to be considered low even though art itself was winning new respect, and successful painters and sculptors sometimes showed their social embarrassment by refusing to take money for their great works. Plutarch calls Polygnotus "not ungentlemanly" because he frescoed a public building without asking for a fee. In Byzantium the court, as the centre of intellectual and social life, was the sole purchaser of art, on behalf of church and state.

During the early middle ages lack of fluid capital prevented dealing in works of art, although there was considerable patronage. However, ecclesiastics like Suger (*c.* 1081–1151), abbot of St. Denis near Paris, in their quest of precious objects with which to adorn their churches, stimulated an interest in these things. There are many instances of traffic in luxury objects such as illuminated manuscripts, statues in Nottingham alabaster and other works of art, which found their way all over Europe. But because of the church's disapproval of commerce, the art trade was restricted and the artist became once more an anonymous artisan. The collapse of feudalism and the breakup of the static equilibrium of early medieval culture led to the renascence of monetary and commercial activity. The birth of an urban *bourgeoisie* brought with it a need for craftsmanship, and artisans and merchants became the two new occupational groups creating a revolution in the trade in works of art. After the 12th century a more or less regular art trade was established, and not only did works of art travel from country to country but artists moved from place to place in order to fill orders from the town corporations and churches.

The rising *bourgeoisie*, through town corporations, exercised important buying power, but not until personal fortunes had grown were individuals able to purchase works of art for themselves. A regular market for art then began to take shape, inducing the artist to leave his lodge and settle in a town as an independent master, selling to individual clients. In the 14th century artists and architects became members of guilds supplying families such as the Strozzi and Medici in Florence, who then outdid the corporations in purchasing works of art. These artistic commissions were mainly gifts to churches or monasteries, and not until the 15th century were works of art bought for personal use in the home or private chapel. The change from commissioner to collector meant that the collector no longer ordered what he needed but bought what he was offered, and this encouraged artists to paint what they themselves wanted; conversely Paolo Uccello, in painting what he wanted, at the same time was perhaps unconsciously satisfying the needs of a wider public with his portable "easel" pictures. Competition between the upper *bourgeoisie* and the papal *curia* for an artist's services caused prices to rise. Along with living artists, whose works were bought by merchants for resale, the antique art trade flourished. In the 16th century there was a regular demand for monuments of the past, which sent dealers looking for excavators and sites. Like a modern art dealer, Giovanni Battista della Palla ordered from artists and acquired from private owners *objets d'art* for the French king.

Something like modern art dealing began in the Netherlands in the 17th century—first the artists themselves sold their own and other pictures, then book and print sellers, jewelers, frame makers and even innkeepers dealt in art. Art dealers became too numerous and the individual townships had to restrict art selling to those who were in the painters' guilds; since many artists were too busy working to trade, it often fell to their apprentices to do so for them. When art-dealing apprentices left the studios to set up independent businesses, they regulated the market and developed a clientele who relied on their advice and went to them for a specific kind of art. This led to individual dealers giving instructions to particular artists to meet special requirements.

The sale of works of art in the modern era can be divided into phases, each characterized by the predominance of a special but nonexclusive relationship between buyer and seller. The most active phases of art marketing, such as auctions and sales from dealers' galleries, have taken place in times of marked political, economic or social change. One of the greatest stimulants to the art market was the sale, after his execution, of the superb collection of Charles I of England. The French Revolution and the Napoleonic Wars both produced mass buying and selling, the results of which founded many of the leading national art galleries of Europe. World Wars I and II stimulated trade in art objects. The extraordinary rise in art prices during the first half of the 20th century was connected with the progressive economic deterioration of Europe, the economic growth of the United States, the devaluation of currencies and racial and national persecutions, which set a premium on works of art as easily transportable securities. Heavy taxation and its accompanying social changes also were responsible for releasing onto the market heirlooms that would normally have remained out of the dealers' hands. Taxation also stimulated art buying: since most countries do not impose any tax on capital gains, the amateur who buys a work of art and sells it at a profit can count the profit as entirely his, while in the United States the tax system induces citizens to buy works of art by offering them a tax deduction in any one year on the appraised value of a work, provided it is handed over to a public gallery upon the purchaser's death.

Art buying, dealing and selling shift from country to country with historical changes. In the 16th century Romans were buyers of art; in the 18th they became sellers to British collectors. In

the 20th century the British became sellers to the U.S. buyer, whose preferences largely have guided the world art markets. Art treasures are considered secure investments by U.S. financial advisers, and the United States' position as the wealthiest capitalist country, together perhaps with a desire to create a cultural background and artistic heritage, has caused one of the greatest booms in art buying. It turned New York into an art capital, competing with Paris and London as the most important art selling and buying centre of the western world.

Various influences were responsible for developing U.S. taste in art. Prominent among them was the Museum of Modern Art, New York (founded 1929), which devoted itself not only to showing new trends in contemporary American and European art but in educating the public in the history and foundation of modern art through its exhibitions, lectures and other activities, which reach to many parts of the world. This activity created unreal prices in specific art trends in which the museum was particularly interested, and the museum's influence over U.S. contemporary taste (and thus over its spending) was so strong that many dealers in Paris and London would not think of handling a modern artist whose work was not either owned or sanctioned by the museum. Another influence in the development of the U.S. art buying public was Lord Duveen of Millbank (*q.v.*). Duveen concentrated only on old masters, since he realized that these could not be replenished and would grow more valuable the rarer they became; his absolute rule of the market during five decades transformed U.S. taste. He caused a price inflation for the works he supported by buying back what he sold at almost the same price and, though the market formed by such a salesman died with him, he implanted a buying frame of mind in the U.S. public.

An indispensable element in the U.S. art market as in others has been the fluctuation of taste. An example of the effects of a revolution in taste may be seen in the discovery in the 19th century of early Renaissance painting. After the time of Raphael (1483–1520), works of art of the preceding three centuries were regarded as curiosities. The reawakening of public taste to a realization of their beauty and value produced a burst of activity in the art market, especially in England, where amateurs had long collected such works. Scholars have influenced popular taste, and the work of the art historians G. B. Cavalcaselle and G. Morelli and later Bernard Berenson (*qq.v.*) had great effect in establishing sound canons of appraisal of the qualities of old masters. More dramatically, contemporary art grew steadily in favour after the 1930s, under the auspices of many museums of modern art, and most new commercial art galleries are devoted primarily to modern art. Extravagant variations in taste produce alterations in price, mostly due to causes that are impossible to analyze. In 1955 Christie's of London sold for £11,500 a work by Titian that had been bought in 1918 for £98; it had always been recognized as a Titian, and there had been no appreciable reassessment of that artist's work.

Sale by Commission.—Artists generally have been active in promoting the sale of their own work, and their relationship with the purchaser has ranged from that of executor of a commission to that of resident painter. In Florence the artists competing for work on doors of the baptistery of the cathedral were kept for a year by the Calimala (wood finishing organization) while they worked on their models and, when Lorenzo Ghiberti was chosen, he was paid a yearly salary while he worked on the doors themselves for 20 years. French painters, such as François Boucher and Jean Honoré Fragonard, could never have succeeded without royal patronage. Although the advent of a new monied class, the artist's own rise in social stature, and organized commercial gallery selling all tended to break up the direct link between artist and patron, yet national or international organizations, government institutions and private businesses still commission works directly from living artists; *e.g.*, Pablo Picasso was commissioned to provide a mural for the United Nations building in New York. In modern times subjects are seldom dictated by commissioners to artists, who usually have freedom to chose their own manner of expression.

Auction Sales.—This method of art dealing did not really become popular until the 18th century in England, when James Cock made Covent Garden a centre of the art world with his famous auctions and even artists, such as William Hogarth, themselves organized private auctions of their work. In 1766 James Christie opened his auction rooms in Pall Mall against the competition of about 60 other auction houses, including Sotheby's, which had been opened in 1744 by Samuel Baker. Christie's concentrated on works of art, and the saleroom became not only an auction house but a place where artists displayed recent work. With the fall of the French monarchy, Paris declined as an art market and London found itself the centre of most European art buying. The combined results of the French Revolution, the Industrial Revolution and the fortunes accumulated during the growth of the British empire made London increasingly important as an international art buying centre, particularly through the auction rooms. Christie's enjoyed a huge success in the fine arts trade and was joined after World War I by Sotheby's, which until that time had specialized in selling books and prints. After World War II these two houses held the lead in international auction sales of fine art, with the Parke-Bernet galleries in New York city and the Galerie Charpentier in Paris.

The success of London's auction houses is attributable partly to the low normal commission rate on sales, 10% as compared with the basic rate of 15% in the United States and 16–21% (on a sliding scale) in Paris. (Also to be taken into consideration in the United States is a New York state sales tax and a federal tax on certain kinds of goods; and in France a sales tax.) Further, there is no import or export duty on works of art entering or leaving England.

Auction sales in England and the United States usually are run similarly: the sale is advertised in prominent magazines and newspapers by the gallery; a "reserve," or minimum price, is placed on the work by the seller so that it does not go too cheaply through lack of bidding; the auctioneer then takes open bids at the auction. The auctioneer, who generally does not accept responsibility for the attributions of the works disposed, is an employee of the auction house and can often "bid up" the work for sale until it reaches its reserve by calling out bids that are not actually made. "Rings," or combinations based on prearranged mutual agreements, may be formed between dealers who bid against outsiders but not against each other.

In Paris, the auction is run by a *commissaire priseur* ("valuer") whose name is advertised with the sale. He is frequently an expert on the objects for sale, and often the success of the auction depends on his reputation. He may hire the auction room himself, he takes a commission on the sales paid by the buyer and assumes the responsibility of the attributions. The bids are written down, collected and handed to the *commissaire priseur*, who then calls them out. This is a secret bid. Of Paris' two most important auction houses, the Galerie Charpentier is privately owned, holding auctions at irregular intervals interspersed with exhibitions, and the Hôtel Drouot is the official government auction house, holding as many as six or seven regularly announced sales daily.

In the Netherlands, the Dutch auction system has been in use for centuries. It is a complicated technique that involves two sales of the same object. For instance, a provisional bidder might go up to 250 guldens for an object but, instead of the sale terminating, it then begins again by the auctioneer calling out double the provisional bid, say 500 gulden. He works backward toward the first price and at any point another bidder can call out "mine," which indicates he wants the object for that price. If this does not happen, the first bidder gets the object at the original price. In order to stimulate bidding during the first part of the sale, the provisional bidder gets a commission on the final sale if he does not get the object.

Art Dealers.—The main spur to art dealing came in the 18th century with the progress of archaeological excavations in Italy, which produced a wealth of statues, marbles, vases and terra cottas, as well as pictures, that were eagerly sought. Rome was the centre of selling where such men as the English banker Thomas Jenkins, the Italian sculptor Bartolomeo Cavaceppi and the

Scottish painter Gavin Hamilton produced and sold the *bric-a-brac* of Hellenistic and imperial Rome. So great was the passion for this activity and so contagious the enthusiasm it engendered that some of the purchasers turned amateur dealers themselves; *e.g.*, Sir William Hamilton and Lyde Browne, the elder, of Wimbledon, who sold his collection of statues to the empress Catherine of Russia for £23,000. Joseph Smith (1682–1770), British consul at Venice, was a prominent art dealer of the 18th century. Major artists have been dealers: the collection of Charles I was amassed partly through the efforts of Rubens, Daniel Mytens and others, while Sir Peter Lely, Sir Godfrey Kneller, Sir Joshua Reynolds and Sir Thomas Lawrence were all dealers as well as collectors.

The 19th century saw the elevation of the picture dealer to his modern position of dominance, in which, rather than merely supplying a prospective consumer with a desired object, he plays an extensive and influential aesthetic role as an active shaper of taste. He acts in liaison between customer and artist and, being in a position to find out quickly what the former expects from the latter, he can suggest to the artist the size, subject and manner most suitable for sale. He constantly looks out for fresh talent. (Ambroise Vollard's "discovery" of the Postimpressionist and Fauve painters in Paris at the beginning of the 20th century won him a place in art history). Dealers who sell contemporary works for artists usually do so on a commission basis, although the artist can often hire the services of the gallery for an exhibition. Occasionally, the dealer pays the artist a fixed sum for all his works and then sells them for whatever price the market will bear, as was the case with the painter Maurice Utrillo and his arrangement with the Petrides brothers.

Sales From Exhibitions.—Another type of selling is that effected through bodies of artists holding at fixed intervals large organized exhibitions, to which outsiders may be invited to submit works and at which sales are made with little or no commission. The most famous of these are the Royal Academy exhibition, London, held annually each summer, and the various academic and independent *salons* in Paris in the latter part of the 19th and at the beginning of the 20th century. Just as in Venice in the 17th and 18th centuries local artists would display their wares once a year in St. Mark's square, so at exhibitions of art in several cities of the United States, artists "claim" a length of railing or boarding on the street and hang their pictures, which are sold to passers-by; and in London similar exhibitions have sprung up, particularly since the 1950s. See also ART FORGERY.

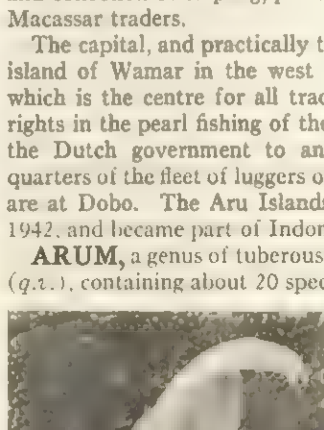
ARU ISLANDS (PULAU-PULAU ARU), the easternmost group of islands in the south Moluccas (*q.v.*) (Maluku province) belonging to Indonesia, lie in the shallow Arafura sea, between 5° 22′ and 7° 01′ S. and 134° 05′ and 134° 52′ E., on the edge of the submarine continental shelf of Australia and New Guinea. They are composed of one large island, Tanahbesar, 122 mi. long and 58 mi. wide, and nearly 100 smaller islands, the total area of the group being 3,306 sq.mi. Tanahbesar, of irregular, oblong form, is virtually divided into five separate islands (Kola, Wokam, Kobroor, Maikoor and Trangan) by three narrow channels of varying width and depth from 10 to 300 ft. They have been variously interpreted as remainders of stream courses which once traversed the former land surface between New Guinea and the Aru Islands or as fault lines. All the islands are low, mostly horizontal layers of coralline limestone, and covered with a dense forest; the coast is often very swampy. The vegetation includes screw pines, palm trees, kanari and tree ferns; in Trangan, the southern portion of Tanahbesar, there are grassy plains, and along the coast and river banks are mangroves.

The population (1956 est.) was 27,006, of mixed Papuan and Malayan stock, as in the Tanimbar Islands, but of darker colour though less dark than that of Papuans proper; smooth rather than curly hair; and thin lips. The natives, divided into *Pata-lima* and *Pata-siwa*, showing influence of Tidore and Ternate, are mostly pagan, though Christianity has made a little headway, and some are Muslims. In the western islands, the Voorwal, where the Muslims and Christians mostly live, including Chinese, Buginese and Macassarese settlers, the villages are near the coast and nearly hidden among clumps of trees. In the eastern islands, the Achterwal, they stand on high rocks. The houses of the pagans are often of rough wood and *atap*, crowded close together; they are entered by a trap door in the middle of the floor.

Usually a shed in the centre of the village harbours the protective spirit of the community to whom offerings are made. The Aru islanders are a gentle quiet people; there is little crime among them, and they retain their old laws and customs and are largely governed by their own chiefs. Many of the men wear a single short garment round the waist and the women a very short and tight sarong, home woven, but they decorate themselves with bead necklaces, anklets, bracelets, earrings of copper, plaited leaves and combs of bone or wood. The animal life is Papuan and includes several birds of paradise, including the king bird of paradise. Many natives find occupation in hunting this magnificent bird for its plumes which are used for ornaments. Little ground is tilled, except by the Christians and Muslims, and the communally owned uncultivated ground is hunted and explored for sago and other food products. Wives are purchased, a man becoming absolute master of his wife, and his brother having the right to marry her on his death. The principal means of subsistence are agriculture (amongst the Voorwal peoples), sale of bird of paradise plumes and collection of trepang, pearl and tortoise shell for Chinese and Macassar traders.

The capital, and practically the only port, is Dobo, on the small island of Wamar in the west where only a few people live but which is the centre for all trade. The islanders retained certain rights in the pearl fishing of the east coasts, which were leased by the Dutch government to an Australian concern. The headquarters of the fleet of luggers obtaining pearls and mother-of-pearl are at Dobo. The Aru Islands were occupied by Japan in Aug. 1942, and became part of Indonesia in 1949. (J. O. M. B.)

ARUM, a genus of tuberous-rooted herbs of the family Araceae (*q.v.*), containing about 20 species found in Europe and the Mediterranean region, and represented in the British Isles by the well-known lords-and-ladies, cuckoopint or wake-robin (*A. maculatum*), which yields the somewhat poisonous Portland arrowroot. The black calla (*A. palaestinum*), native to Syria and Palestine, is a greenhouse plant resembling the calla lily.



J. HORACE MCFARLAND CO.

LORDS-AND-LADIES (ARUM MACULATUM)

Arum is also the common or popular name for several other plants related to the genus *Arum* but considered generically distinct. Among them are the water arum (*Calla palustris*), several calla lilies (*Zantedeschia*) and some plants in the genera *Anthurium* and *Arisaema*. All have an acrid or poisonous juice. See CALLA; CUCKOOPINT. (N. Tr.)

ARUNDEL, EARLS OF. The question of deciding who was first earl of Arundel is complicated by the admission by the crown in 1433 of a claim by John Fitzalan (*see* below) that the earldom was and always had been vested in the castle of Arundel. Had this claim been investigated, which it was not, it could have been shown that the assertion was untrue. Nevertheless, applied retrospectively, the admission of 1433 would mean that ROGER DE MONTGOMERY, who came to England from France in 1067 and was created an earl, with lands in Sussex including Arundel castle, is

to be considered 1st earl of Arundel, though he was known by other titles; *e.g.*, earl of Chichester. (*See* also SUSSEX, EARLS AND DUKE OF.) He was succeeded by his two sons, but in 1102 the 3rd earl was exiled and attainted, and his honours and estates were forfeited to the crown.

In 1138 WILLIAM D'AUBIGNY married Adelaide, widow of Henry I, and acquired Arundel castle as part of her dowry. He was confirmed in possession of the castle and honour of Arundel by Henry II in 1155. HUGH, the 5th in this line, died in 1243, and his estates were divided among his sisters and cousins and their children, Arundel castle passing to his nephew, JOHN FITZALAN. Neither John nor his son appears to have been known as earl of Arundel. Moreover, all of the above-mentioned earls appear to have been merely earls "at" Arundel. RICHARD FITZALAN (1267–1302), who was made earl of Arundel probably in 1289, seems to have been the first to be specifically so created. He is, therefore, here considered as the 1st earl, though, by virtue of the claim of 1433, he is held by some to be the 8th earl (in the d'Aubigny line). Richard fought for Edward I in Wales, France and Scotland and died on March 9, 1302.

He was succeeded by his son, EDMUND (1285–1326), 2nd earl, who married Alice, sister of John de Warenne, earl of Surrey. A bitter enemy of Piers Gaveston, Arundel was one of the ordainers appointed in 1310; he declined to march with Edward II to Bannockburn, and after the king's humiliation he was closely associated with Thomas, earl of Lancaster, until about 1321 when he became connected with the Despensers by the marriage of his son with Isabella, daughter of the younger Hugh. Thenceforth he sided with the king. He was executed at Hereford by the partisans of Queen Isabella on Nov. 17, 1326.

Edmund's son, RICHARD (*c.* 1313–76), 3rd earl, who obtained his father's earldom and lands in 1331, led one of the divisions of the English army at Crécy and took part in the siege of Calais; he also fought in the naval battle with the Spaniards off Winchelsea in Aug. 1350. He was one of the regents of England in 1355 and died on Jan. 24, 1376. His marriage to Isabella was annulled in 1345. By his second marriage he left three sons, the youngest of whom, Thomas, became archbishop of Canterbury, while the eldest, RICHARD (1346–97), became 4th earl of Arundel and of Surrey. This Richard was a member of the royal council during the minority of Richard II, and about 1381 was made one of the young king's governors. About 1385 he joined the baronial party led by the king's uncle, Thomas of Woodstock, duke of Gloucester, and in 1386 was a member of the commission appointed to regulate the kingdom and the royal household. As admiral of the west and south he gained a victory over the French and their allies off Margate in 1387. Then came the king's futile attempt to arrest Arundel, which was the signal for the outbreak of hostilities. The Gloucester faction quickly gained the upper hand, and the earl was again a member of the royal council. After a personal altercation with the king at Westminster in 1394 Arundel underwent a short imprisonment. In 1397 he was involved in a conspiracy against Richard II and was beheaded on Sept. 21.

Richard's only surviving son, THOMAS (1381–1415), 5th earl, was made by Richard II a ward of John Holland, duke of Exeter, from whose keeping he escaped about 1398 and joined his uncle, Archbishop Thomas Arundel, at Utrecht, returning to England in 1399 with Henry of Lancaster, afterward King Henry IV. In Oct. 1400 he was restored to his father's titles and estates. Arundel joined the party of the Beauforts and was one of the leaders of the English army that went to France in 1411; then after a period of retirement he became lord treasurer on the accession of Henry V and was at the taking of Harfleur in 1415. He died on Oct. 13, 1415. His wife was Beatrice (d. 1439), a natural daughter of John I, king of Portugal, but he left no children, and the lordship of Arundel passed to his second cousin, JOHN (1385–1421), Lord Maltravers, who was summoned to parliament as earl of Arundel in 1416.

John's son JOHN FITZALAN (1408–35), 7th earl, did not secure the earldom until 1433, when as the "English Achilles" he had already won great distinction in the French wars. He was created in 1434 duke of Touraine and continued to serve Henry VI in the field until his death from wounds, on June 12, 1435, at Beauvais. The earl's only son, HUMPHREY (1429–38), died in April 1438, when the earldom passed to John's brother WILLIAM (1417–87), the 9th earl, and the dukedom of Touraine became extinct. William was succeeded by his son THOMAS (1450–1524), 10th earl.

HENRY FITZALAN (1512–80), 12th earl, son of WILLIAM (1483–1544), 11th earl, by Anne, daughter of Henry Percy, 4th earl of Northumberland, was born on April 23, 1512, and succeeded to the earldom in 1544. He took part in the siege of Boulogne (1544) and was appointed lord chamberlain and a privy councilor in 1546. He was one of the council of 12 appointed by Henry VIII to assist the executors of his will during the minority of Edward VI. He was twice arrested and twice released on various charges at the instigation of Northumberland. In June 1553 he alone of the council refused the "engagement" of the council to support Edward's "device" for the succession which passed over his sisters, Mary and Elizabeth, as illegitimate, in favour of Lady Jane Grey, though he signed the letters patent. On Edward's death, while pretending to support Northumberland, he secured the proclamation of Mary as soon as Northumberland had left London. Under Mary I he held a series of high appointments, including the lord stewardship which he retained under Elizabeth I. But as one of the leaders of the Catholic nobility he fell under suspicion, resigned his offices in 1564 and was more than once disgraced. In 1569 he was implicated in the intrigues of Thomas Howard, 4th duke of Norfolk, but although he appears to have received money from Spain, the evidence against him was insufficient, and he was released in March 1570 and even recalled to the council. After the discovery of the Ridolfi plot he was once more arrested and liberated only after the execution of Norfolk in 1572. He died on Feb. 24, 1580. At his death the title passed through his daughter Mary, the wife of the beheaded Norfolk, to the Howards.

PHILIP HOWARD (1557–95), 13th earl of Arundel, eldest son of Thomas Howard, 4th duke of Norfolk, executed for high treason in 1572, and of Lady Mary, daughter and heiress of Henry Fitzalan, 12th earl of Arundel, was born on June 28, 1557. He was married in 1571 to Anne, daughter and coheiress of Thomas Dacre, Lord Dacre. On the death of his maternal grandfather in Feb. 1580 he became earl of Arundel. In 1582 his wife became a Roman Catholic and was committed to the charge of Sir Thomas Shirley by the queen. He was himself suspected of disloyalty and was regarded by the discontented Roman Catholics as the centre of the plots against the queen's government and even as a possible successor. In 1583 he was with some reason suspected of complicity in Francis Throckmorton's plot and prepared to escape to Flanders, but his plans were interrupted by a visit from Elizabeth I at his house in London and by her subsequent order to confine himself there. In Sept. 1584 he became a Roman Catholic and made another attempt to leave England. He was then brought before the Star Chamber and sentenced to a fine and imprisonment for life. He was released for a time but was again arrested on a charge of high treason and, in 1589, condemned to death. The sentence was not executed, and he died in the Tower of London on Oct. 19, 1595. Arundel wrote three treatises on virtue. In 1929 he was beatified.

THOMAS HOWARD (1585–1646), 14th earl of Arundel, and earl of Surrey and of Norfolk, son of Philip, 13th earl of Arundel and of Lady Anne Dacre, was born on July 7, 1585, and educated at Westminster school and at Trinity college, Cambridge. On April 18, 1604, he was restored to his father's earldoms of Arundel and Surrey and to the baronies of his grandfather, Thomas, 4th duke of Norfolk. His fortunes fluctuated under James I and Charles I; he held many high offices and was more than once imprisoned. In 1641 as lord high steward he presided at the trial of the earl of Strafford. This closed his public career. He again became estranged from the court, and in 1641 he escorted Marie de Médicis to Holland, remaining abroad, with the exception of a short visit to England in that winter, and taking up permanent residence at Padua, Italy. He contributed a sum of £54,000 to the king's cause and suffered severe losses in the Civil War. On June 6, 1644, he was created earl of Norfolk. He died at Padua, when on the point of returning home, on Oct. 4, 1646.

The 14th earl is best remembered for his patronage of the arts and for his magnificent collections. These were dispersed after his death, most of the marbles and statues being given to Oxford university in 1667 to become known later as the Arundel (or Oxford) marbles. The library was given to the Royal society and to the College of Heralds, the manuscript portion of the Royal society's moiety being transferred to the British museum in 1831 and forming the present Arundel collection.

In 1606 the 14th earl married Alathea, daughter and heir of Gilbert Talbot, 7th earl of Shrewsbury, by whom, besides three sons who died young and one daughter, he had James, who predeceased him, HENRY FREDERICK (1608–52) who succeeded him as 15th earl of Arundel and earl of Surrey and of Norfolk, and William Howard, Viscount Stafford, executed in 1680. Henry Frederick's son THOMAS (1627–77), 16th earl, succeeded by the reversal (1660) of the attainder of 1572, to the dukedom of Norfolk, in which the earldom has since been merged.

ARUNDEL, THOMAS (1353–1414), archbishop of Canterbury and chancellor of England, who played an important part in politics during Richard II's reign, and was a determined opponent of the Lollards (*q.v.*). He was the third son of Richard Fitzalan, earl of Arundel and Warenne, by his second wife, Eleanor, daughter of Henry Plantagenet, earl of Lancaster. In 1373 Thomas Arundel was archdeacon of Taunton, and in April 1374 he was consecrated bishop of Ely.

During the early years of Richard II's reign Arundel belonged to the party led by Thomas, duke of Gloucester; Henry, earl of Derby (afterward King Henry IV); and his own brother Richard, earl of Arundel. In 1386 he became chancellor for three years, and in 1388 archbishop of York. In 1391 he became chancellor again, but resigned in 1396 on his appointment as archbishop of Canterbury. In the following year Gloucester, Warwick and Arundel were arrested and he himself was impeached by the commons on a charge of complicity in forcing a council of regency on Richard during his minority. He was condemned and banished, and at the same time demoted from Canterbury to St. Andrews. At the end of 1397 he left England for Rome, and joined Henry of Lancaster. (The Thomas Arundel whom according to Froissart the Londoners sent to encourage Henry to assume the English crown was apparently not the bishop, but his nephew and namesake, the earl of Arundel.) In 1399 he accompanied Henry to England, where he became chancellor again for a few days and also archbishop of Canterbury. He witnessed the abdication of Richard and crowned Henry IV on Oct. 13.

The main work of his later years was the defense of the church and the suppression of heresy. He was instrumental in passing the statute *de haeretico comburendo* (1401) under which William Sawtrey was the first Lollard to be burned. He successfully opposed the attempts to disendow the church made by the parliament of 1404, but he was unable to persuade Henry to pardon Archbishop Scrope. In 1407 he became chancellor again for two years. During this period he passed constitutions against the Lollards at Oxford. In 1411 he went on an embassy abroad, and in 1412 he became chancellor for the last time, until the accession of Henry V. He took a leading part in the proceedings against the Lollard Sir John Oldcastle, Lord Cobham. He died on Feb. 19, 1414, and was buried at Canterbury.

See *The Cambridge Medieval History*, vol. vii, ch. 15 (1949) and vol. viii, ch. 11 (1936); W. A. Pantin, *The English Church in the Fourteenth Century*, ch. 2 (1955). (PL. GN.)

ARUNDEL, a municipal borough of West Sussex, Eng., is situated 11 mi. E. of Chichester and 21 mi. W. of Brighton by road. Pop. (1961) 2,617. It lies on a hill slope above the river Arun, and its castle, rising from the summit of the hill, was placed to guard not only the passage along the river through the South Downs to the north but also the east-west route along the coastal plain.

The first mention of the place is in 877 as Harundell (O.E., Harhundell, "horehound valley"; the plant horehound being prolific in the neighbourhood). In the time of Edward the Confessor it seems to have consisted of a mill and an earthwork, but it appears in Domesday Book as a thriving borough and port. It was the head of one of the six rapes (administrative divisions) of Sussex and was granted by William the Conqueror to Roger de Montgomery, who restored and extended the castle on the site of the earthwork. From very early times, markets were held within the borough on Thursday and Saturday, and in 1285 a grant of two annual fairs in May and December was obtained by Richard Fitzalan, earl of Arundel, but neither markets nor fairs are now held. In 1580 the earldom passed to the Howards, of whom Sir John Howard had been created 1st duke of Norfolk in 1483. The borough returned two members to parliament from 1295 to 1832 and one member until 1868. Arundel is a borough by prescription and in 1586 Elizabeth I acknowledged its incorporation and ancient rights. Once a flourishing river port, it is now a quiet country town with considerable tourist traffic in summer. The canal that linked it with Chichester harbour is dry. The town was partially destroyed by fire in 1338.

Arundel castle, which has long been one of the seats of the dukes of Norfolk, was frequently assaulted and greatly damaged in the Civil War. However, it was repaired and improved by Thomas, 8th duke of Norfolk, between 1716 and 1720 and was restored by Charles, 11th duke (d. 1815), and Henry, 15th duke (d. 1917), who between them made it one of the most splendid baronial mansions in England. There is a beautiful park of 1,100 ac. containing Swanbourne lake. The Perpendicular parish church of St. Nicholas, rebuilt in 1380, contains fine ironwork and wall paintings. The eastern part, which belongs to the duke of Norfolk is walled off from the remainder and only entered from the castle precincts. Formerly the collegiate church of the Holy Trinity and now known as the Fitzalan chapel (Roman Catholic), it contains memorials of the Fitzalan and Howard families. The Gothic Roman Catholic church of St. Philip Neri (cathedral of the Arundel and Brighton diocese) was built by Henry, 15th duke of Norfolk, in 1873. *See* also ARUNDEL, EARLS OF.

ARUNDELL OF WARDOUR, THOMAS ARUNDELL, 1ST BARON (*c.* 1562–1639), son of Sir Mathew Arundell of Wardour castle, Wiltshire, served with great distinction as a soldier of fortune under the emperor Rudolf II against the Turks, and was created a count of the Holy Roman empire. His assumption of a foreign title was strongly resented by Elizabeth I, who sent him to the Fleet prison on his arrival in England in 1596. He was soon released, but next year was again imprisoned for a short time on another charge. James I gave him his English peerage in 1605, but he repeatedly fell under suspicion because of his Catholic faith during the reigns of James I and Charles I. He died on Nov. 7, 1639. Arundell was a devout Catholic, but the accusations of disloyalty made against him appear to have been unfounded.

His grandson, HENRY ARUNDELL (*c.* 1607–94), 3rd baron, who succeeded in 1643, fought on the Cavalier side in the Civil War. At the Restoration he regained the family estates and became an officer of the queen's household. He was employed by Charles II in negotiating the treaty of Dover. Denounced by Titus Oates as a participator in the "Popish plot," Arundell, with four other Roman Catholic peers, was impeached and imprisoned. He was released in Feb. 1684. After the accession of James II, the charge was annulled, and Arundell was for a time keeper of the privy seal. He died on Dec. 28, 1694.

ARUNTA (ARANDA). The description of this Australian tribe in W. B. Spencer's and F. J. Gillen's classic of 1899 made a great impact on studies in social anthropology and comparative religion; the Arunta became famous. They occupied a pear-shaped region of about 25,000 sq.mi. in central Australia. It included the upper Finke river and its northern tributaries, the MacDonnell ranges and the Todd and Hale river courses east of Alice Springs. The rainfall varies from 5 to 10 in. a year in different parts.

Having migrated across deserts into this comparatively hospitable region, the Arunta increased. The groups that hived off to occupy new food-gathering grounds remained separated for months each year and for longer periods during droughts. As a result, there are five Arunta subtribes, marked by differences in dialect and in some cases also in social organization, in ritual practices and in doctrinal emphasis. Each regards itself as the true Arunta.

Material equipment included the nonreturn boomerang, a barbed wooden spear and an ovate-shaped spear thrower with a stone chisel fixed on the handle end. Fire was produced by sawing the hardwood edge of the spear thrower across the softer wood of the shield.

Behaviour was, and is, based on classificatory kinship. Marriage is between the children of cross-cousins, own or classificatory. In the southern division, kinship, marriage and descent rules are correlated with a four-section system, but in the rest of the tribe with an eight subsection system of grouping relations and of codifying ritual affiliations. Both systems spread from the northwest. Polygyny was practised.

The doctrine of pre-existence and reincarnation was fundamental. Human spirits sojourned in centres where the ancestors of the *Altjiranga* (the "Dreaming"), the creative era, performed significant acts and rituals, or left parts of their bodies or died. A person whose conception was realized near such a centre was a reincarnation of a local ancestor. The ancestors were also in totemic relationship with natural species and phenomena (*see* TOTEMISM). Men whose pre-existent spirits were associated with a particular totemic centre performed rituals which caused the "souls" or "emanations" to go forth from it and increase the species in due season. During ritual, the creative past became operative in the present. Males had to pass through long and severe initiation training and ordeals (including circumcision and subincision) before being admitted to totemic rituals with their sacred chants and symbols (*tjurunga*), be the latter permanent of wood and stone, or objects made for the occasion only. Sorcery caused illness and death. "Pointing bone" technique was believed in. Doctor-men, who had passed through special revelatory rites and training, could cure, protect and also exert psychological influence in general. Burial ritual expressed the social value of the individual. The body was interred.

Arunta art, mainly geometrical and symbolical, was mostly temporary, being expressed on ritual paraphernalia and on the bodies of the actors. A modern group of Arunta has become successful as water-colour artists, specializing in landscapes. The language is complex and very rich and, as in other tribes, is a suitable medium for aboriginal poetical powers.

Greatly reduced in numbers during the first 70 years of contact, the Arunta showed signs by the 1960s of holding their own and even of increasing, as a result of readaptation, medical services and greatly improved conditions. *See* AUSTRALIAN ABORIGINES.

See W. B. Spencer and F. J. Gillen, ***The Native Tribes of Central Australia*** (1899); T. G. H. Strehlow, ***Aranda Traditions*** (1948).

(A. P. E.)

ARUSHA REGION, TANGANYIKA: *see* NORTHERN REGION, TANGANYIKA.

ARVAL BROTHERS, in Roman antiquities, a college or priesthood (*Fratres Arvales,* "brothers of the field"), consisting of 12 members, elected for life from the highest ranks in Rome, and during the empire always apparently including the emperor. (The British museum contains a bust of Marcus Aurelius in the dress of a *Frater Arvalis.*) Their chief duty was to offer annually public sacrifice for the fertility of the fields. There is proof of the high antiquity of the college, which was said to have been older than Rome itself, in the verbal forms of the song with which, down to late times, a part of the ceremonies was accompanied, and which is still preserved. No mention of the *fratres* occurs in Cicero or Livy, and literary allusions to them are very scarce; but there remains a long series of the *acta* or minutes of their proceedings, drawn up by themselves and inscribed on stone. Excavations (1570–1869) in the grove of the Dea Dia about 5 mi. from Rome yielded 96 of these records, dating from A.D. 14 to 241. The brotherhood, almost forgotten in republican times, was revived by Augustus. In his time the college consisted of a master (*magister*), a vice-master (*promagister*), a *flamen* and a *praetor,* who were assisted at the sacrifices by four chorus boys, sons of senators, having both parents alive. Each wore a wreath of corn, a white fillet and the *praetexta* (a characteristic garment of prepubertal boys). The election of members was by co-optation on the motion of the president, who, with a *flamen,* was elected for one year.

The great annual festival was held in honour of the anonymous Dea Dia, a field deity of uncertain identity, on three days in May. It is a matter of dispute whether this festival was identical with that called Ambarvalia (*q.v.*). The ceremony of the first day, on which a sumptuous banquet took place, followed by a distribution of doles and garlands, was held in Rome itself. On the second and principal day of the festival the ceremonies were conducted in the grove of the Dea Dia. They included a dance in the temple of the goddess, at which the song of the brotherhood was sung, in language so antiquated that it was hardly intelligible (text and translation in Mommsen, ***History of Rome***) even to Romans of the time of Augustus.

Special mention should be made of the ceremony of purifying the grove, which was held to be defiled by the felling of trees, the breaking of a bough or the use of any iron tools. The song and dance were followed by the election of officers for the next year, a banquet and races. On the third day the sacrifice took place in Rome, and was of the same nature as that offered on the first day. The *Arvales* also offered sacrifice and solemn vows on behalf of the imperial family on Jan. 3 and on other extraordinary occasions. The brotherhood is said to have lasted till the time of Theodosius. A small frieze of the Antonine period found near Lyons may represent the actual sacrificial ceremony of the *Arvales* to the Dea Dia.

(R. B. LD.)

ARVE, a river of eastern France, is a tributary of the Rhône, which it joins in Switzerland below Geneva. Rising in Savoy in the heart of the Alps, the Arve collects the drainage of the northwestern side of the Mont Blanc massif, and about Chamonix its valley separates that massif from the Aiguilles Rouges to the west. Below the basin of Sallanches, in the northern portion of the great longitudinal valley that lies between the crystalline core of the Alps and the limestone Préalpes, the Arve turns northwest to traverse the prealpine zone by the gap between the Chablais and Bornes massifs. There it occupies a valley through which Alpine ice debouched on to the Alpine foreland during the Great Ice Age. Below Bonneville, in the district known as Faucigny, the Arve valley is wide, low-lying and highly cultivated, though broken by morainic hills. The valley is the gateway to Chamonix (*q.v.*) and the glaciers and highest peaks of the French Alps, and its course of over 62 mi. presents some of the finest and most varied Alpine scenery. (AR. E. S.)

ARVERNI, the ancient Celtic tribe of the modern region of Auvergne in central France whose chieftain, Vercingetorix (*q.v.*), led the great rebellion against Julius Caesar in 52 B.C. In the previous century they had built a considerable empire in southwestern Gaul, but their chief, Bituitus, was overcome by the Romans in 121, and the new Roman province of Gallia Narbonensis pushed the tribe northward beyond the mountain range of the Cévennes. A weakness of the coalition of the year 52 between Arverni and Aedui was their rivalry for Gallic primacy, but the rebels severely defeated Caesar at the Arvernian hill fort Gergovia before Vercingetorix surrendered at Alesia (*q.v.*). Under the empire, although they assisted Vindex' rising in A.D. 68, the tribe seems to have been peaceful and prosperous, with the status of *civitas libera* or "free city." Their capital was moved to Augustonemetum (modern Clermont-Ferrand), and the sanctuary there of Mercurius Dumias on the Puy-de-Dôme summit became famous.

(G. E. F. C.)

ARYABHATA (b. 476), Hindu astronomer and mathematician, was born at Kusumapura near Pataliputra (Patna), India, on the upper Ganges. He was the author of the *Aryabhatiya,* written in verse couplets, which gives the rules of mathematics as known in his time. (*See* also CHRONOLOGY: *Hindu.*) Most of this work deals with astronomy and spherical trigonometry, the remainder consisting of 33 rules in arithmetic, algebra and plane trigonometry, including quadratic equations, the sums of powers of the first *n* natural numbers and a table of sines. The work was published in Sanskrit at Leiden, Neth., in 1874 (French trans., 1879).

Aryabhata gave a very accurate value for pi (π), $3\frac{177}{1250}$ (3.1416), and he taught that the daily rotation of the heavens was a mere appearance due to the axial rotation of the earth. (D. McK.)

ARYAN, a Sanskrit word meaning "noble," was once commonly used to refer to the entire family of languages now known as "Indo-European"; it was also used, more restrictively, as the name of the Indo-Iranian subdivision of that family. In modern times, particularly in National Socialist Germany, the term became infected with political connotations that have made it almost useless. Even in the purely linguistic meaning, common in the 19th century, it has been abandoned. *See* also INDO-EUROPEAN; INDO-ARYAN LANGUAGES. (J. WH.)

ARYA SAMAJ, a vigorously reforming sect of modern Hinduism, founded in 1875 by Swami Dayanand Saraswati (1824–83) at Bombay. Swami Dayanand established the Arya Samaj (Society of Aryas) on the basis of the Vedas (*see* SANSKRIT LITERATURE) as divinely revealed; he denounced all later additions and commentaries as false. The Vedas, as interpreted by the method laid down by Dayanand, may be said to be the theology of the Arya Samaj and are held to contain all truth and all knowledge, including the basis for modern science. The Arya Samaj is completely opposed to idolatry, is sternly monotheistic and denies the efficacy of priestly intervention. Its organization and services are strongly reminiscent of Protestantism.

The Arya Samaj opposes the caste system, based upon birth, as un-Vedic and insists that caste should reflect merit. Among its active reforms have been opposition to child marriage and to untouchability, which it works to eliminate. It is organized in local *samajas*, which send representatives to provincial *samajas* and to an all-India *samaj*. Each local *samaj* elects its own officers in a democratic manner. By 1931 the Arya Samaj was estimated to have upwards of 1,000,000 members; no reliable figures are available after that date.

The Arya Samaj has sought to revitalize Hindu life and to instill self-confidence and national pride among Hindus. It has established a network of excellent schools and colleges, including the Dayanand Anglo-Vedic college in Lahore, which teach rigorously in the Vedas and in modern sciences. It has also built missions, orphanages and homes for widows, while undertaking famine relief and medical work.

O'Malley, *Popular Hinduism* (1935); R. W. Scott, *Social Ethics in Modern Hinduism* (1953); H. Mukherjee and U. Mukherjee, *The Growth of Nationalism in India* (1957); O. Lewis and V. Barnouw, *Village Life in Northern India* (1958); J. N. Farquhar, *Modern Religious Movements in India* (1915); Lala Lajpat Rai, *The Arya Samaj* (1915). (R. I. C.)

ASA, in the Bible, son (or perhaps brother) of Abijah, and third king of Judah (I Kings xv, 9–24), *c.* 911–870 B.C. He was a contemporary of Baasha, Zimri and Omri of Israel, but little is recorded of his long reign except some religious reforms and conflicts with Baasha. Baasha fortified Ramah, 5 mi. N. of Jerusalem, and Asa bribed the king of Damascus to renounce his league with Baasha and attack him. Baasha was forced to retreat, the building material which he had collected at Ramah being used by Asa to fortify towns to the immediate north of Jerusalem. The Book of Chronicles relates a story of a sensational defeat of Zerah the "Cushite," and a great religious revival in which Judah and Israel took part (II Chron. xiv–xv, 15). Asa was succeeded by his son Jehoshaphat (*q.v.*).

ASAFETIDA, a gum resin obtained chiefly from an umbelliferous plant (*Ferula foetida*), allied to the giant fennel (*q.v.*), native to Iran and Afghanistan. It grows to five or six feet, and when four years old is ready for yielding asafetida. The stems are cut down close to the root, and a milky juice flows out which quickly sets into a solid resinous mass. A freshly exposed surface of asafetida has a translucent, pearly white appearance, but it soon darkens in the air, becoming first pink and finally reddish-brown. In taste it is acrid and emits a strong onionlike odour because of the presence of organic sulfur compounds.

The gum resin is relished as a condiment in India and Iran, and has been used in Europe and the U.S. in perfumes and for flavouring. In the regions of its growth the whole plant is used as a fresh vegetable, the inner portion of the full-grown stem being regarded as a luxury.

ASAHIGAWA, a city of Hokkaido, Japan, on the Ishikari river, is in the agriculturally important Kamikawa basin. Settled by government subsidized farmer soldiers in 1893, Asahigawa became the railway, agricultural marketing and industrial centre of northern Hokkaido. Asahigawa's industries include brewing, especially *sake* (rice wine), lumber, pulp and wood products and cotton textiles. Pop. (1960) 188,309. (J. D. EE.)

ASANSOL, a town in the Burdwan district of West Bengal, India, is situated in the heart of the Raniganj coal field, 132 mi. W. of Calcutta, on the Eastern railway. Pop. (1961) 103,405. Area 4 sq.mi. The Grand Trunk road runs right across the town from east to west, and on both sides of it stand shops, offices and hotels. Asansol is the headquarters of a subdivision and is of growing industrial importance. It is an outstanding centre of the coal trade, and a railway centre with a large railway workshop and a railway colony. Jaykaynagar, a suburb of Asansol, has a big aluminum works. (S. P. C.)

ASARABACCA (*Asarum europeum*), a low, stemless perennial plant of the birthwort family (Aristolochiaceae), native to the woods of Europe and north temperate Asia, and occurring wild in some English counties. The allied North American species are commonly called wild ginger. Asarabacca is a small creeping herb with a pungent, aromatic rootstock, kidney-shaped leaves and small purplish bell-shaped flowers. It was formerly grown for medicinal purposes, the underground stem having cathartic and emetic properties.

ASBEST, a town in Sverdlovsk *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the eastern flank of the Urals, 37 mi. E.N.E. of Sverdlovsk, on a branch railway from the main Sverdlovsk-Tyumen line. Pop. (1959 census) 60,053. It owes its existence to the presence of asbestos, first discovered in 1720. It is the largest asbestos mining and processing centre of the U.S.S.R., the vicinity of the town supplying most of the Soviet Union's annual production of 150,000 tons. (R. A. F.)

ASBESTOS, a general term applied to any mineral that can be easily separated into flexible fibres and that can be spun or felted to make noncombustible fabrics.

The name is derived from the ancient Greek name for a fabulous stone that, once set on fire, could not be quenched, probably quicklime.

The noncombustible character and spinning qualities of asbestos fibre were undoubtedly known to the ancient world. Plutarch mentions "perpetual" lampwicks used by the vestal virgins, and Pausanias records a lamp with a wick that was not consumed, being made of "Carpasian linen," or mineral fibre from Carpasius in Cyprus. Shrouds of woven asbestos appear to have been used in ancient times for the cremation of nobility, and thus Pliny refers to it as *linum vivum*—"the funeral dress of kings." The beginning of the modern asbestos industry was in 1868, when 200 tons of raw material were produced in Italy.

Varieties.—Of the several types of asbestos, chrysotile, the fibrous variety of serpentine, is the most important; the others all belong to the amphibole group of minerals of which anthophyllite, amosite, crocidolite and tremolite-actinolite are the principal varieties.

Chrysotile, the fibrous form of the mineral serpentine (*q.v.*), constitutes the bulk of commercial asbestos. It is a hydrous magnesium silicate with the chemical composition $Mg_3Si_2O_5(OH$. The individual fibres are white, but the colour of the aggregate in the veins varies from green to greenish-yellow to amber. The chief occurrence of chrysotile is in veins in altered peridotite associated with massive serpentine, where the asbestos may be found either as cross fibre, roughly perpendicular to the vein walls, or as slip fibre, parallel to the walls. The fibres range in length from $\frac{1}{16}$ to $1\frac{1}{2}$ in. in most deposits but in places may be as long as 12 in. The world's greatest deposits of this type are in Quebec, Can., and the Ural mountains, U.S.S.R. Only 5% to 10% of the rock mined is asbestos; the remainder is serpentine.

Chrysotile also occurs in limestone near the contact with small

intrusions of basic igneous rock. The average fibre in these deposits is longer than that found in peridotites but is frequently harsher and less flexible. Asbestos deposits in the Transvaal, Republic of South Africa, and Arizona are of this type.

Anthophyllite, a magnesium-iron silicate, $(Mg,Fe)_7Si_8O_{22}(OH)_2$, is an orthorhombic amphibole. It is characteristically in long coarse fibres having low tensile strength. Anthophyllite is of little commercial importance although small amounts have been mined in South Africa and in Maryland and California.

Amosite, an iron-rich anthophyllite, is characteristically found in cross-fibre veins with fibres usually several inches in length. It is variously coloured and may be brown, gray or yellowish-green. Amosite is more brittle than chrysotile but is more acid resistant and thus has specialized uses. The world's supply of amosite comes entirely from the Republic of South Africa.

Crocidolite is a soda-iron, monoclinic amphibole, $Na_2(Fe_3{}^{2+}$-$Fe_2{}^{3+})Si_8O_{22}(OH)_2$. It occurs in cross-fibre veins up to three inches wide with a characteristic dull blue colour and for this reason is commonly referred to as blue asbestos. It has a higher tensile strength than chrysotile but is less resistant to heat and fuses to a black glass at a relatively low temperature. Some crocidolite is found in Australia and in Bolivia, but the major commercial source is South Africa, where it is found in a siliceous rock rich in iron known as ironstone.

Tremolite-actinolite are monoclinic amphiboles and the type referred to under the names amphibole asbestos, hornblende asbestos or merely asbestos. The chemical composition of tremolite is expressed by the formula $Ca_2Mg_5Si_8O_{22}(OH)_2$; iron may substitute in part for magnesium, and when it reaches 2% the mineral is called actinolite. Pure tremolite asbestos is white, but actinolite is green.

Tremolite asbestos characteristically is fine and silky and occurs in slip-fibre veins. This is the original material to which the name asbestos was given. The fibres of some amphibole asbestos instead of being easily separated are interwoven into a felted mass. If the aggregate is in thin flexible sheets, it is called mountain leather; if in thick sheets it is called mountain cork. Both varieties are light gray to white in colour and have an apparent specific gravity of less than 1.

Uses.—Because asbestos is incombustible and is capable of being woven into fabrics, it is a valuable industrial material. Crude asbestos is graded into nine main groups, but only the best grades are spinning fibre. To be of high commercial value asbestos must possess length and fineness of fibre combined with infusibility, toughness or relatively high tensile strength and flexibility. Asbestos fibre resembles fine polished wire, free from serrations of any kind that would add to the difficulties of spinning. Under high magnification, fibre is seen to consist of numerous fine threads crowded together. The longer fibre can be carded and spun into yarns, either alone or with additions such as cotton or small sizes of brass or copper wire. Spun products are woven into fabrics of varying weights, thickness and densities to meet numerous industrial needs.

Some of the principal uses are for drop curtains in theatres, for fireproof wall linings and for boiler pipe packing. Yarns spun with fine wire are used for fabric for brake linings; woven asbestos belts convey cement clinker and other hot products. When impregnated with rubber, asbestos is utilized for heat insulation and for gaskets. Asbestos yarns, impregnated with graphite and suitable greases, are used for steam and pump packings; ropes, cords, twine and threads are made for various purposes. Asbestos gloves and other articles of clothing are worn by firemen and by workers in foundries and other places where fire is a hazard. Various products are used to insulate electric conductors; fibre shorter than spinning stock is used for making coverings for steam pipe, hot-water pipe and boilers. Certain classes of short asbestos fibre are mixed with cement or gypsum and molded into various shapes for special purposes or pressed into millboard, wallboard, corrugated siding, shingles or tiles. Asbestos sheets deaden sound, and asbestos papers are used where dampproof and fireproof coverings are required. Short fibres are used as an ingredient in paint and roofing cements.

Production and Consumption.—The consumption of asbestos fluctuates from year to year, but in general there was a steady increase after about 1930. The industry expanded rapidly after World War II, with Canadian production increasing especially after the early 1950s. Prospecting for new deposits was intensified, and there were increased efforts to develop substitutes and synthetics. The world consumption of asbestos of all grades in 1930 was 338,783 tons; by 1950 it had risen to an estimated 1,200,000 tons and in the second half of the 20th century approached 2,000,000 tons. Approximately 60% was produced in Canada, 6% in the Republic of South Africa, 6% in Southern Rhodesia (Federation of Rhodesia and Nyasaland), 4% in the United States, 2% in Swaziland, 2% in Italy and the balance mostly in the U.S.S.R. Data were not available from the U.S.S.R. after 1938, when 86,000 tons were produced, but output was estimated at about 16% of the world total. About 95% of the world production is chrysotile asbestos.

Asbestos products are manufactured in the United States, England, U.S.S.R., France, Germany, Austria, Italy, Canada, Spain, Belgium and Australia. The United States is the largest user, ordinarily consuming nearly half of the world's output; about 95% of this amount is usually imported.

ASBJØRNSEN, PETER CHRISTEN (1812–1885), and **MOE, JØRGEN ENGEBRETSEN** (1813–1882), collectors of Norwegian folklore whose *Norske folkeeventyr* is a landmark in Norwegian literature, were closely united in their lives and work and are rarely named apart. Asbjørnsen was born in Christiania (Oslo) on Jan. 15, 1812. The son of a glazier, he had to give up medical studies and at the age of 20 became a private tutor in eastern Norway, where he began to collect folk tales. He had met Moe, born at Hole in Ringerike on April 22, 1813, when Moe was 14. Moe, the son of a rich and highly educated farmer, graduated in theology from Christiania university in 1839; religious scruples combined with ill-health made him give up thoughts of the ministry and he became a tutor, spending holidays in collecting folklore in southern Norway. Meanwhile Asbjørnsen had become a naturalist and made investigations along the fiords for Christiania university, adding all the time to his collection of tales. When in 1837 Moe discovered this, he urged a joint publication, to which Asbjørnsen agreed.

Their main problem was one of form: the Norwegian literary style of the day was too like that of Denmark to be suitable for national folklore, while the various dialects of the actual narrators were too local for the purpose. A new style had to be forged. Finally they adopted the Grimms' principle, in their *Kinder- und Hausmärchen*, of reproducing tales in their traditional and popular form, without dialect, but in a simple language. In 1837 the first tales appeared in *Nor*, and some were then published as *Norske folkeeventyr* ("Norwegian Folk Tales") in 1841. Further collections, enlarged and illustrated, appeared in 1842, 1843 and 1844, the whole being published in 1852 with critical notes. The influence of this work was striking. Accepted all over Europe as a major contribution to comparative mythology, it was widely translated, the most popular English version being Sir George Dasent's *Popular Tales From the Norse* (1859). In Norway it provided a national source of inspiration and a stylistic model to young writers. It is usually said that the vigour of these concise and humorous tales came from Asbjørnsen and their charm from Moe, but in fact, although Asbjørnsen was a jovial man and Moe a quietly reflective one, their contributions are indistinguishable.

Each, however, published individual works. In 1845 Asbjørnsen published *Norske huldreeventyr og folkesagn*, a collection of fairy tales, in descriptive settings. In 1856 he was appointed forest

master and was sent by the government to examine methods of timber preservation in various other European countries. In 1860 he introduced Darwin's *Origin of Species* to the Norwegian public. He died in Christiania on Jan. 5, 1885.

In 1850 Moe published a set of lyrics which placed him among the first and best Norwegian romantic poets. *I brønden og i kjaernet* (1851) and *En liden julegave* (1860) are books of stories for children. In 1853 he eventually took holy orders, and rose to be bishop of Christiansand in 1875. He died there on March 27, 1882.

See Sir Edmund Gosse, *Studies in the Literature of Northern Europe* (1879); Illit Grøndahl and Ola Raknes, *Chapters in Norwegian Literature* (1923).

ASBURY, FRANCIS (1745–1816), the first bishop of the Methodist Episcopal Church consecrated in America, arrived in Philadelphia late in 1771. There were then in the colonies but three Methodist meeting houses and about 300 communicants. Forty-five years later, when his incredible labours ended, there were nine annual conferences and 412 Methodist societies with a membership of 214,235. When he began his work, Methodism was confined almost wholly to America's eastern shore. At the close of his career the movement had spread over every state east of the Mississippi river, then the nation's western boundary. He organized scores of Methodist societies, ordained more than 4,000 preachers, traveled approximately 270,000 mi.—mostly on horseback over rough roads and unsurveyed mountain paths—and preached more than 16,500 sermons. He crossed the Alleghenies 60 times. "My horse trots stiff," he wrote in his journal, "and no wonder when I have ridden him upon an average of 5,000 miles a year for five years successively."

Francis Asbury was born at Handsworth, Staffordshire, four miles from Birmingham, on Aug. 20, 1745, the son of Joseph and Elizabeth Rogers Asbury. His father was a yeoman, a humble, hard-working man; his mother, of Welsh descent, was devoutly religious and was confident that her son would become a great religious leader. At the age of 14 he experienced a spiritual awakening and began to attend meetings for Bible reading and prayer. With very limited schooling he was licensed as a local preacher. Admitted at 21 to the Wesleyan conference, for four years he served as an itinerant preacher. In Aug. 1771, when at a conference John Wesley called for volunteers to go to America, Asbury responded first. After eight days at sea he wrote in his journal: "Whither am I going? To the New World. What to do? To gain honour? No, if I know my own heart. To get money? No; I am going to live to God, and bring others so to do." This was his purpose to the last.

He landed at Philadelphia on Oct. 27, 1771, and left on Nov. 6, 1771, on his first itinerary. He acted independently in making his plans. He began by preaching in inns, jails and by the wayside—wherever he found hearers. Soon he was made Wesley's general assistant. With this authority he proceeded to enforce Wesley's rules for his preachers and societies. There was iron in his character. He determined to stand against all opposition, "stedfast as a wall of brass." He insisted that every preacher must travel a circuit. When the American Revolution broke out and pro-British sympathizers departed, Asbury, convinced that independence was inevitable, remained. At the Christmas conference (Dec. 1784), when the Methodist Episcopal Church was organized, he refused to accept from Wesley appointment as general superintendent, insisting that election must be by vote of the preachers. For long years he was not well, yet, suffering intolerable pain and distress, so weak that he had to be lifted from his sulky, he continued to travel and preach. He died on March 31, 1816.

Asbury was not a learned man or, from the standpoint of sermon composition, a great preacher. He preached on simple themes with such deep earnestness that his preaching carried conviction and resulted in decision and in changed lives for great numbers of people. His *Journal and Letters* were published in three volumes (1958). *See* also METHODISM: *United States.*

ASBURY PARK, a city of Monmouth county, N.J., U.S., was founded in 1871 by James A. Bradley who named the seaside resort for Rev. Francis Asbury, the first U.S. bishop of the Methodist Church. Bradley guided the development of the community until his death in 1921. It became a borough in 1874, and a city in 1897. In 1933 it adopted a council-manager form of government. (For comparative population figures *see* table in NEW JERSEY: *Population.*) The community attracts many New Jersey resort visitors, ranking second only to Atlantic City. Prominent sites along the beach boardwalk are the Auditorium and the Convention hall.

Asbury Park was the scene of a spectacular ship disaster in Sept. 1934, when the "Morro Castle" caught fire at sea in a northeast gale and was beached near the Convention hall, where the ship continued to burn, with a loss of 134 lives. (E. R. D.)

ASCALON (ASHKELON or ASKALON), an ancient city of Palestine. Its now desolate site, on the coast of Israel 12 mi. N. of Gaza, occupies a rocky amphitheatre including about ¾ mi. of shore with traces of a harbour in the southwestern area. From the sand-swept terrain shattered columns and remnants of ruined buildings testify to former greatness. The site is plentifully supplied with wells, and vines, olives and fruit trees flourish in the fertile coastal plain. An Israelite settlement, Migdal Ashkelon, stands near the ancient site.

History.—Traces of habitation reach back to about 2000 B.C., and Ascalon appears in the Egyptian execration texts of about this time. In the Amarna letters (14th century B.C.) Ascalon is one of the cities that ask the Pharaoh to provide assistance against the Apiru (Habiru); it would appear that Ascalon was allied with Gezer and Lachish against Abdu-Khepa, the prince of Jerusalem. In the 13th century Ramesses II stormed Ascalon; the town had evidently rebelled with Hittite encouragement. About 1220 B.C. certain Palestinian cities, among them Ascalon, rebelled against their Egyptian overlord Merneptah: "Carried off is Ascalon" sings the Egyptian poet of the period. Ascalon is not mentioned among the cities of Judah in Josh. xv, and it appears as a Philistine city, one of the Pentapolis, from the days of Samson to the 6th century. Tiglath-pileser III (745–727 B.C.) of Assyria received tribute from Mitinti of Ascalon, who later revolted. Sennacherib captured the city in 701 when Sidqia refused to submit; Sidqia, his wife, children and brothers, together with the city gods, were deported to Assyria, and Sarru-lu-dari, son of Rukibtu, their former king, was installed as ruler. Subsequently Ascalon was a vassal of Esarhaddon and Ashurbanipal (*qq.v.*). Nebuchadnezzar met stiff opposition in the Philistine plain and was forced to capture and destroy the city, deporting the leading citizens to Babylon (604 B.C.). Conquered by Alexander the Great, the city became Hellenized, and following his death its fate as a vassal was determined alternately by the Ptolemies and by the Seleucids. Though it was a centre of Hellenism, it opened its gates to the Jewish leader Jonathan Maccabaeus (147) and later to Alexander Jannaeus. Herod the Great, who adorned it with monumental buildings, was born there. From 104 B.C., for four and a half centuries it was a free city of the Roman empire. In A.D. 636 it passed into Arab hands.

During the crusades (*q.v.*) Ascalon was the key to southwestern Palestine. Baldwin III of Jerusalem completed the Frankish conquest of Palestine in 1153 after a successful six-month siege of Ascalon. In 1187 it was retaken by Saladin after feeble resistance; he burned the city and demolished its defenses at the approach of Richard I Coeur-de-Lion in 1191. Richard promptly set about restoring it, but under the terms of a truce the following year the walls were once more destroyed and the city abandoned. In 1240 Richard of Cornwall began rebuilding, but in 1270 the Mameluke sultan Baybars I, in accord with his scheme of defense, destroyed the fortifications and blocked the harbour with stones. Ascalon was the scene of fighting between British and Turkish armies in World War I.

Excavations.—After a preliminary survey in 1913, the Palestine Exploration fund organized operations there (1920–23) under

the supervision of J. Garstang and W. J. Phythian-Adams. Herod's cloisters—the "court surrounded by columns" of Josephus —were exposed and a number of statues, among them one of Isis-Tyche, were recovered. The stratification of the site was determined and a date of about 2000 B.C. for the earliest traceable habitation established. Distinctive Philistine ware appears after the destruction of the Canaanite town about 1200 B.C.

ASCANIAN DYNASTIES, branches of a German family influential from the 12th century to 1918. The name, adopted during the first quarter of the 12th century, was derived from Aschersleben, where the counts of Ballenstedt had a castle in the midst of possessions northeast of the Harz mountains. Albert the Bear (*q.v.*) was the first to raise the family's rank from that of count to margrave. Having been invested with the North mark in 1134, he extended it east of the Elbe to form the mark of Brandenburg (*q.v.*). These lands remained under the senior branch of the Ascanians till it became extinct in 1320. In 1180, meanwhile, on the fall of Henry the Lion, duke of Saxony and Bavaria, Bernard, one of Albert's younger sons, had obtained those of Henry's territories in the Elbe region which carried the title duke of Saxony. In 1260 these lands were divided into two duchies, Saxe-Lauenburg in the northwest and Saxe-Wittenberg in central Germany, for the sons of Bernard's son Albert. Saxe-Wittenberg, which secured the Saxon electoral title in 1356, passed in 1423, on the extinction of the Ascanian branch there, to the margraves of Meissen (of the house of Wettin). Thus the name Saxony, which originally belonged to a tribal land in the North German plain, was transferred to the southeast and to the upper Elbe (*see* SAXONY). The Ascanians of Saxe-Lauenburg, however, lasted till 1689. Yet another Ascanian principality was Anhalt (*q.v.*), the basis of which was formed when the original possessions of the family (from Aschersleben to Zerbst and Dessau) passed to Bernard's elder son Henry in 1212. The Ascanians ruled in Anhalt till 1918.

See H. Krabbo, *Regesten der Markgrafen aus dem askanischen Hause* (1910–20). (H. Lz.)

ASCARIS, the genus name of certain roundworms (class or phylum Nematoda) that are parasitic on various animals. *A. lumbricoides*, the giant intestinal roundworm that infects man (especially children), is prevalent in warm, moist areas where conditions of sanitation are inadequate. Closely allied forms are *A. suis*, found in pigs, and *A. megalocephala*, in horses. *See* also ROUNDWORM; PARASITOLOGY: *Roundworms*.

ASCENSION, a small British island of volcanic origin in the south Atlantic, lies 700 mi. N.W. of St. Helena (*q.v.*). Area 34 sq.mi. The island is within the influence of the southeast trades (latitude 8° S.) and the lee side is subject to "rollers," which break on the shore with great violence. Green Mountain, a huge elliptical crater, is 2,870 ft. above the sea, while the surrounding tablelands vary from 1,200 to 2,000 ft. Steep ravines, lined with masses of lava and ending in small bays, are typical. The climate is remarkably healthful. The average rainfall is about 6 in. in Georgetown on the coast and 25 in. on Green Mountain, March and April being the rainy months. The natural vegetation includes purslane, rock roses, ferns and mosses. The island is the resort of sea turtles, which come in thousands to lay their eggs on the shores between January and May. Like St. Helena, the island does not possess any indigenous vertebrate land animals. There are some wild donkeys and goats, rabbits, wild cats and a few partridges. The "wideawake" birds (sooty terns) frequent the island in vast numbers to lay their eggs.

The island was discovered by the Portuguese João da Nova Castella on Ascension day, 1501. It remained uninhabited till after the arrival of Napoleon at St. Helena (1815), when it was garrisoned by the British government. A settlement named Georgetown (locally known as Garrison) was made on the northwest coast. The island was under the rule of the admiralty till 1922, when it was transferred to the administration of the colonial office and made a dependency of the colony of St. Helena. The local manager of Cable and Wireless, Ltd., serves as resident magistrate. The population in 1963 was estimated at 475. In World War II the island was used as a refueling base for U.S. aircraft and in 1957 a station was constructed on it as part of the U.S. long-range proving ground for guided and ballistic missiles. Britain's first overseas civil satellite communications station was completed there in 1966.

See E. H. Ford, *The History and Postage Stamps of Ascension Island* (1933); C. C. Watts, *In Mid Atlantic* (1936), "Ascension Island," *Scot. Geogr. Mag.* (Jan. 1933); *Colonial Report* on St. Helena (biennial). (J. D. HA.)

ASCENSION, FEAST OF THE, the 40th day after Easter, commemorating the taking up of Jesus Christ into heaven, as witnessed by the apostles, apparently on Mt. Olivet (Mark xvi, 19; Luke xxiv, 51; Acts i, 1–11). Ranking with Christmas, Easter (*qq.v.*) and Pentecost in the universality of its observance among Christians, the feast was celebrated as early as the end of the 4th century, according to testimony of Etheria, Chrysostom, the historian Socrates and Augustine. Augustine, in fact, declares that in his day it was already celebrated "in all the world."

A distinctive feature of its liturgy in the western church is the extinguishing of the paschal candle after the gospel has been chanted, as a symbol of Christ's leaving the earth. Despite the idea of separation indicated in this act, which might be expected to set a note of sadness, the whole liturgy of Ascension-tide, through the ten days to Pentecost, is marked by joy in the final triumph of the risen Lord. One of the central themes is the kingship of Christ (hence the frequent use of Psalms xxiv and xlvii in the liturgy of the feast); and a theological implication is that the Ascension is the final redemptive act conferring a share in the divine life on all who are members of Christ. In the words of the Roman preface, Christ "was lifted up into heaven so that he might make us partakers of his Godhead."

In the middle ages, the people's delight in the visual and dramatic found an outlet in various ritual practices that came to be associated with the feast. A procession, in imitation of Christ's journey with his apostles to the Mount of Olives, and the raising of a crucifix or a statue of the risen Christ through an opening in the church roof were widespread customs identified with Ascension. *See* also CHURCH YEAR.

L. D.)

ASCETICISM. The Greek word from which asceticism derives means practice or training for the attainment of an ideal or goal; it was applied to soldiery, athletics, and learning, as well as to virtue and piety. In modern usage, however, the term is commonly employed to mean a religious exercise or exercises, often involving difficulty and pain, by which self-conquest in a physical or spiritual sense is promoted and eventually more or less perfectly achieved. While asceticism often is looked upon as a preparation for mysticism (*q.v.*), current usage tends to restrict it to the realm of merely human activity; mysticism, on the contrary, implies a state in which the divinity acts and the soul remains more or less passive.

Asceticism is found in practically all religions but especially in those that profess dualism or stress the opposition of soul and body, of the divine and the world (*see* DUALISM). It is practised (1) to avoid or frighten away a divine force that is conceived as evil; (2) to prepare for union with a divine force in order to be strengthened; (3) to please a divinity by offering sacrifice; and (4) to make reparation for sin and thus attain to holiness.

In general the practices of asceticism may be divided into spiritual and physical. Spiritual ascetical practices include silence, guard of thoughts, spiritual reading, prayer, obedience, and the acceptance of humiliation. Physical practices may be either negative or positive. Negative practices often are concerned with food, drink, and sex, consisting in abstention from certain food and drink either for a time or permanently, or in decreasing the intake of food or drink, and in temporary or permanent abstention

from sex relations. Positive asceticism is practised by enduring heat or cold, embracing homelessness, living in a narrow cell or on a pillar, using hard beds or rough clothing, going barefoot, reducing the amount of sleep or sleeping in an uncomfortable posture, going on pilgrimage, omission of bathing and other bodily care, remaining immobile in certain positions, lying on spike beds, wearing chains or other painful bonds, flagellation, and self-mutilation, etc.

Asceticism can be practised individually, as by hermits, or socially in convents and monasteries. Magic and magical practices also often involve asceticism. Indeed according to some authorities there is a magical as well as a religious asceticism, the magical being profane and this-worldly in purpose. In this view, however, religious and magical asceticism are inextricably interwoven. Often magical asceticism can be equated with a kind of mysticism.

Judaism.—Asceticism in early Judaism was limited, since God was acknowledged as creator of the world and of the body. The principal forms were abstention from sex relations (Ex. xix, 15) and fasting, which was practised in times of bereavement, pestilence, war, etc. (Joel i, 13 ff.; Jer. xxxvi, 6). In the Old Testament asceticism usually was practised to move the deity to mercy, but on occasion its purpose was mystical. Among the several ascetic practices of the Nazirites was abstention from wine. The Essenes renounced personal property, practised obedience and silence, and engaged in hard labour. But even the Qumran community, which seems to have been the most ascetical Jewish sect, was far from considering asceticism an end in itself.

In late and contemporary Judaism, asceticism also occupies a subordinate position. Its principal practice seems to be observance of the Law, *e.g.*, in its prescriptions in regard to food, etc.

Greek Religion.—In Greek religious practice asceticism was a peripheral phenomenon, confined for the most part to certain cults. Orphism imposed abstention from animal food and beans. Early Pythagoreanism, which seems to have been influenced by Orphism, also practised ascetical silence; later, dualism led it to widen its ascetical practice. Greek philosophy, especially that of the Cynics and Stoics, tended to be in practice ascetical.

Christianity.—Jesus imposed an ascetical program when he described the life of his followers as a narrow way along which they were to carry their cross (Mark viii, 34). Self-denial and self-abnegation also were stressed. The Christian is to prefer Christ to his nearest and dearest (Luke xiv, 26), to expect persecution (Matt. x, 23), and to watch and pray (Mark xiii, 33). This evangelical asceticism is conceived as principally interior, since merely exterior devotion, fasting, and almsgiving have no value (Matt. vi). Moreover love of God and the neighbour are conceived as more meritorious than asceticism.

During the centuries before monasticism became prominent, a number of ascetical practices appear. In the 2nd and 3rd centuries the prospect of martyrdom was ever present to many Christians. The widespread practice of chastity arose at the same time. In the early 3rd century a study of the theory of asceticism was made by Clement of Alexandria and Origen. Under the influence of Greek philosophy, they concluded that it was necessary in Christian living for the purification of the passions, as a means of loving God more, and as the gateway to mysticism. During the 4th century monasticism united in itself the currents of Christian asceticism. Various practices were experimented with, and the heroes of asceticism (*e.g.*, the pillar saints) became popular heroes.

In the medieval West, Christian perfection was placed by St. Thomas Aquinas and other theologians in the fulfillment of the commandments of love of God and the neighbour. All Christians, no matter what their state or condition, were held to be called to this perfection. Asceticism, in some instances extreme, was conceived as a means to progress in holiness and as a help in the struggle against sin.

At the time of the Reformation, the Protestant leaders in principle rejected asceticism as a perversion of the Gospel. The doctrines of the depravity of human nature and of justification by faith alone, as well as the rejection of good works, undermined the theoretical foundations of asceticism. The Christian life in itself (soul free, to conquer the world in the world, as Troeltsch put it) and not the ascetical life was Luther's ideal. As a matter of fact, however, much asceticism was carried over into Lutheranism from its Catholic antecedents. Calvinism and pietistic Protestantism went further in this direction; in some instances as far as Puritanism. Methodism and some of the Baptist denominations further revived asceticism.

At a time when Protestants were breaking away from medieval practice in this matter and the humanists were decrying asceticism St. Ignatius Loyola in his *Spiritual Exercises* standardized Roman Catholic practice for the modern period. He noted that exterior asceticism was employed either to make reparation for past sins, or to overcome oneself by bringing the lower faculties into subjection to the higher, or to obtain some grace or gift from God. He also summarized a balanced program of exterior asceticism when he wrote:

> The first kind of exterior penance concerns eating. In this matter, if we do away with what is superfluous, it is not penance but temperance. We do penance when we deny ourselves something of what is suitable for us. The more we do this, the better the penance, provided only that we do no harm to ourselves and do not cause any serious illness. The second kind of penance concerns sleep. Here, too, it is not penance when we do away with the superfluous in what is pampering and soft. But it is penance when in our manner of penance we take away something from what is suitable. The more we do this the better it is, provided we do not cause any harm to ourselves and do not bring on any notable illness. But we should not deny ourselves a suitable amount of sleep, except to come to a happy mean in case we had the habit of sleeping too much. The third kind of penance is to chastise the body, that is to inflict sensible pain on it. This is done by wearing hairshirts, cords, or iron chains on the body, or by scourging or wounding oneself, and by other kinds of austerities. The more suitable and safe form of penance seems to be that which would cause sensible pain to the body and not penetrate to the bones, so that it inflicts pain, but does not cause sickness. For this end it would seem more suitable to chastise oneself with light cords that cause superficial pain, rather than in any other way that might bring about serious internal infirmity (Exercises 82–86 from *The Spiritual Exercises of St. Ignatius: a New Translation*, by Louis J. Puhl, S. J., The Newman Press, Westminster, Md., 1951.)

St. Ignatius like St. Benedict and the other Roman Catholic masters put more stress on interior asceticism—*i.e.*, on obedience, silence, and humility—than on exterior. Instead of encouraging men to harden themselves by striving to become heroes of physical endurance, they shifted the emphasis to the interior, from the flesh to the spirit.

Recent times, perhaps, have witnessed a decline of exterior asceticism in the church, although Charles de Foucauld (*see* FOUCAULD, CHARLES EUGÈNE, Vicomte de) is one of the most striking examples of penitential holiness in the history of Christianity. (E. A. R.)

Eastern Religions.—Asceticism has classically had an important place in the religious life of the East, especially in Hinduism and Buddhism. The earliest scriptures of Hinduism, the Vedas, speak of a strange figure, the "long-haired" *muni* (Rigveda x, 136, 3–5), who by means of various ascetic practices was able to achieve states of ecstasy and execute extraordinary feats, such as flying through the air. Of a similar nature was the *vratya* (Atharvaveda xv, 3 ff.), who by asceticism and such physical acts as breath control (*pranayama*) was capable of achieving a wide range of magical powers (*siddhis*). It appears that these early ascetics stood outside the orthodox Aryan community, possibly as representatives of earlier, indigenous cults. However, by the time of the early Upanishads (*c.* 600 B.C.) ascetic practices of all sorts were evidently regarded as appropriate to and in a sense necessary for the attainment of a variety of goals, whether religious (*e.g.*, spiritual liberation) or otherwise (*e.g.*, mundane happiness, magical powers, the indefinite prolongation of life).

Although the ancient ascetic practices were many and varied, they were comprehended in a single word—*tapas* ("heat"). In the Vedas, where the word occurs infrequently, *tapas* refers to inner pain or "heat" created by the practice of physical austerities. Hence it came to mean any religious penance or act of privation or torture that was voluntarily assumed or self-inflicted. In later Hinduism the practice of *tapas* was especially associated with the psychophysical discipline of Yoga (*q.v.*) as the means by which

the *yogi* achieved supernatural powers and extraordinary states of consciousness. Among the austerities prescribed in the sacred literature are silence, difficult and usually painful bodily postures, physical privations, and self-tortures. The ultimate purpose of such exercises has been, of course, the attainment of spiritual liberation (*moksha*)—freedom from the limitations of matter and from the cycle of rebirth and the realization of ultimate reality (spirit, God). Over the centuries there have appeared within sectarian Hinduism many orders of ascetics, several of them reputedly founded by great religious figures, such as Shankara, Ramanuja, and Madhva. These ascetics have exercised a considerable influence upon popular piety, if for no other reason than that the giving of alms to monks (*sadhus*) and nuns (*sadhvis*) brings spiritual rewards to the laity. Moreover, ascetics have been regarded as possessing supernatural powers to see the future, to heal infirmities, and to dispel evil.

In Buddhism asceticism has had a somewhat different nature and significance. On the one hand its renunciation of the world and the flesh was more complete than that contained in the Hindu doctrine of the Four Stages (*ashramas*) of Life, which ordained as the normal course the practice of austerities (*tapas*) and celibacy only after one had fulfilled the duties of a householder, begetting children and enjoying material possessions. In early Buddhism the monastic life of celibacy and poverty was regarded as the norm, the only path to Enlightenment. On the other hand Buddhism denounced as unprofitable the excesses of self-mortification and other austerities that have characterized Hindu asceticism. According to tradition, in the course of his own efforts to gain Enlightenment Gautama Buddha tried the way of extreme asceticism and found it profitless. Thus he cautioned his disciples against the extreme of self-torture as well as that of self-indulgence and advocated a "middle way."

From the standpoint of physical austerities, then, Buddhist asceticism was generally more moderate than that of Hinduism. The Buddhist monk (*bhikkhu*) and nun (*bhikkhuni*), having renounced all worldly attachments (including family and material possessions), were to cultivate virtue, self-awareness, and compassion and to avoid any excess of sentiment and action (such as *tapas*) that would lead to pain and disquiet the mind. The goal of Buddhist asceticism was simplicity of life and its practice was moral discipline and mental training rather than self-torture and physical privation. In fact the body was to be properly cared for (bathed, rested, fed) as the necessary vehicle for reaching Enlightenment. At the same time, however, it was to be regarded as completely ephemeral and vile, and the monk, strictly controlling the senses and the passions, was to meditate upon the inherent corruptibility and ugliness of the flesh.

Of other Eastern religions, Islam has also had a place for asceticism, although it never was so prominent or comprehensive an aspect of that religion as it was of Hinduism and Buddhism. Indeed it may be said that although all devout Muslims are obliged to undertake as religious duties certain privations (*e.g.*, fasting during the month of Ramadan, abstinence from alcoholic drinks), the Koran and the Holy Law are strikingly nonascetic in tone. Nonetheless a fully developed asceticism did establish itself in the mystical school of Islam, Sufism (*q.v.*). The Sufis generally regarded the material world, including the body, as a threat to the highest spiritual development. Thus, claiming to follow the ascetic examples of the prophets, they ordained poverty, fasting, chastity, mendicancy, and, in some instances, self-torture as paths to the ultimate goal of *fana'*, self-annihilation, making possible union with God. (H. P. S.)

ASCH, SHOLEM (1880–1957), novelist, playwright and short-story writer, the most turbulent and controversial figure in Yiddish literature and also one of the most internationally acclaimed. Born in Kutno, Poland, on Nov. 1, 1880, he received a traditional Jewish education, though close association with Christians exposed him to a strong non-Jewish influence. He began professional writing at 19; his first triumph came in 1904 with *Dos Shtetl*, a prose work which cast a romantic glow over Jewish life and also introduced the *leitmotiv* of all his work—his religious mysticism, which, as later developed, distinguished between "faith," which unites, and "religion," which divides. Asch's preference for "faith," disregarding historic differences, was unacceptable both to Jews and to the more orthodox Christians, although his books were widely read and praised by the religiously minded. In 1907 he wrote *God of Vengeance*, a play which introduces on the stage a brothel in which a Holy Scroll of the Law is installed; it aroused violent Jewish public reaction to what was considered a sacrilege and a defamation. With the outbreak of World War I Asch settled in the United States and continued writing, mainly novels; he wrote almost entirely in Yiddish, his books being translated into German and then into English and other languages. *Salvation* (1934; literal title "The Jew of the Psalms") is considered the peak of his art and contains the epitome of his philosophy. His famous Christological series began with *The Nazarene* (1939), a novel in the grand manner, presenting Jesus Christ in the likeness of the gospels; it was followed by *The Apostle* (1943), a huge, sprawling work dealing with St. Paul, and *Mary* (1949). All were great popular successes. In his later years Asch lived in England and then in Israel, where he was accepted with mixed feelings; he died in London on July 10, 1957, while on a visit there.

ASCHAFFENBURG, a town in Bavaria, Ger., lies on the right bank of the Main river near the foot of the Spessart mountains, 26 mi. S.E. of Frankfurt. Pop. (1961) 54,131. The Renaissance castle of Johannisburg, of red sandstone, replaced a former castle destroyed in 1552 which stood on the site of the Roman castrum overlooking the river. It was built in 1605–14 as a residence for the archbishops and electors of Mainz. In the chapel are an alabaster high altar and a pulpit by Hans Junker. The 12th-century church of SS. Peter and Alexander on the Stiftsberg in the old part of the town contains the predella with the "Lamentation of Christ" by Mathias Grünewald (*q.v.*) and a Romanesque crucifix. On the north side of the church is a 13th-century cloister. Collections in the Stadt and Stift museum include manuscripts and paintings taken from the castle in 1945. The town's main industries are the manufacture of men's clothing, coloured paper and machine and precision tools. Originally a Roman settlement, Aschaffenburg came under the jurisdiction of Mainz toward the end of the 10th century. It was fortified in 1122. In 1292 a synod was held there, and in 1474 an imperial diet, preliminary to that of Vienna, at which the Aschaffenburg Concordat was decided. In 1814 the town became Bavarian and in 1866 the Prussians defeated the Austrians in the neighbourhood.

ASCHAM, ROGER (1516–1568), English scholar and writer, famous for his enlightened humanism and for his prose style, was born at Kirby Wiske, near York. His father, John Ascham, of a family well known in Yorkshire, was steward to Lord Scrope of Bolton. He sent all his three sons to Cambridge: Thomas, fellow of St. John's college in 1523; Anthony, a graduate in medicine (M.B.) in 1540, author of books of popular medicine and almanacs; and Roger. As a boy, Roger was taken into the family of Sir Humphrey Wingfield, a lawyer and official of the prominent Wingfield family of Suffolk, who lived at Brantham, near Harwich. Wingfield, as Ascham later wrote affectionately, "ever loved and used to have many children brought up in learning in his house," providing a tutor, his chaplain Robert Bonde, and training them also in archery.

The same patron sent Ascham in 1530 to St. John's college, Cambridge. This was the time when the new Renaissance enthusiasm for the classics, especially Greek, was at its height; after Ascham had qualified to teach, he wrote enthusiastically in 1543 (new style), "Aristotle and Plato are now read by the boys in their original language . . . Sophocles and Euripides are now more familiar to us than Plautus when you were here . . . Yet we do not treat the Latin writers with contempt, but we cherish the best of them who flourished in the golden age of their literature." This study not only made competent scholars, but also prepared for state employment those who could write effective Latin.

Ascham took his B.A. degree in 1533 (old style; 1534, new style), and was elected a fellow of St. John's. The M.A. followed in 1537, and he was appointed reader in Greek in the university. Though he rejoiced in the company of the many enthusiastic scholars, he was dissatisfied with his income of £4 a year, and he sought higher patronage. He first offered his learning to the archbishop of York by translating into Latin an early Greek biblical commentary; he also dedicated to the king a treatise on archery which exhibited both classical learning, on which Henry prided himself, and concern for military training. The work, *Toxophilus* ("lover of the bow"), was published in English in 1545. Henry granted Ascham an annuity of £10, at that time an adequate living.

Ascham was made public orator of the university in 1546, and in this capacity wrote many official letters. But he was soon to depart. His teacher and friend Sir John Cheke, the first regius professor of Greek, had gone to court as tutor to Prince Edward; William Cecil, also of St. John's, had begun the official career which was to make him Elizabeth's chief minister; and Ascham's own pupil, William Grindal, followed Cheke to become tutor to Princess Elizabeth. When Grindal died in 1548, Ascham in turn became her tutor in Greek and Latin for two years; then, by Cheke's influence, he was appointed secretary to Sir Richard Moryson, English ambassador to the emperor Charles V. The ensuing three-year service took Ascham to Augsburg, Innsbruck, aside to Venice, and back by the Rhine cities to Brussels and home; he wrote many of the envoy's dispatches, and also (such was the force of classical enthusiasm) read Greek authors with him. He was appointed Latin secretary to Edward VI; in 1553 he was confirmed in this post by Queen Mary (his earlier outspoken Protestantism notwithstanding), and in 1559 by Queen Elizabeth. He served Elizabeth until his death on Dec. 30, 1568, not only as the composer of official letters to foreign rulers (like John Milton a century later), but also as not the least among the humanists who adorned her court, reading Greek with her, and welcomed for his learning and his conversation.

Ascham severed his connection with Cambridge in 1554 when he married Margaret Howe, who bore him three sons, Giles, Dudley and Sturm (named after the great German teacher). When his son Giles entered Westminster school, he made his father's letters accessible to the headmaster Edward Grant, a recent graduate of St. John's college; Grant brought out an edition of them in 1576, the first of seven editions, and the first separate edition of the correspondence of an English humanist. Grant praised the letters for their Latin style, but they are most important for their revelations of Ascham's personal history, or, in the case of the private letters written home from Germany, for their observation of the religious wars there. One such letter was published separately as a very incomplete *Report and Discourse of the Affairs and State of Germany* (1570).

Ascham wrote two books, both in English. The *Toxophilus* was written as a dialogue, in the manner which Renaissance humanists had learned from Cicero. The first or learned part demonstrated the military importance of the bowman from the Parthians to the contemporary Turks, while the second discussed archery as a sport (its position was like that of cricket today), dealing with both the training of the archer and the care of the instruments. The book's chief value is that of the familiar essay, with its warm personal interest and its observation of everyday life.

The Schoolmaster is Ascham's better-known work; it exists in the first manuscript draft of 1564, and in the expanded version of 1568 which was published by Ascham's widow in 1570. The title applies to only a small part of the book, which presents an effective method of teaching Latin prose composition, the heart of English classical education. A larger concern of the book is with the "psychology of learning" (to use a modern term), and Ascham discussed with mature wisdom the qualities needed in a student, and characteristically deplored the general use of corporal punishment both at school and at home. His greatest concern is with what would now be called the education of the whole man, and he recommends training in manners and morals as Sir Thomas Elyot had done in *The Governor* (1531). Ascham was shocked by the behaviour of the "great ones" of the land, which permitted the wildness and "italianate" behaviour of youth. The book contains much vivid observation, as well as eloquence in stating an intellectual and moral ideal of personality in a lively, individual style. The humanity of the book and of its author makes Ascham the outstanding literary personality of the generation following that which had been dominated by Sir Thomas More. As an enlightened and engaging writer of English prose Ascham is assured a steady literary fame.

Bibliography.—The only complete edition of the writings and letters of Ascham is that of J. A. Giles, *The Whole Works,* 3 vol. published as 4 (1864–65). The two books and the *Report* were edited as *The English Works* by W. Aldis Wright (1904). The letters written in English were edited from the manuscripts by Albert McHarg Hayes (Princeton dissertation, typescript, 1933). The life by Edward Grant, published with the letters in 1576, is included in the Giles ed., vol. iii. *See* also Alfred Katterfeld, *Roger Ascham. Sein Leben und seine Werke* (1879). (G. B. P.)

ASCHELMINTHES, a problematical phylum of microscopic to small, pseudocoelomate wormlike animals that includes the following classes (some of which are themselves often given phylum rank): Gastrotricha, Kinorhyncha, Nematomorpha, Priapulida, Rotifera (*qq.v.*) and Nematoda (*see* Roundworm).

ASCHERSLEBEN, a town in Germany in the district of Halle, is a railway junction and is situated some 30 mi. N.E. of Halle. Pop. (1964) 35,641. It lies in the region of the extensive potash deposits on the northern edge of the lower Harz mountains and most of the people are employed in the potash-mining industry. There is a brown coal mine just north of the town and the Mansfeld copper slate deposit to the south. Aschersleben became especially known for its seed raising, and many nationally owned and private seed-raising enterprises supply grain and vegetable seeds to the entire German Democratic Republic. Farming is carried on in the area. The chief industries are tool, paper and cloth manufacture. Aschersleben was probably founded in the 11th century by Count Esico von Ballenstedt, ancestor of the house of Anhalt; it received municipal rights on the Halberstadt model in 1266. On the death of Otto III (1315) it passed to the bishop of Halberstadt and, after 1648, to Brandenburg. The town hall dates from 1518.

ASCITES, the term in medicine applied to an effusion of noninflammatory fluid within the peritoneal cavity. It is not a disease in itself but is one of the manifestations of disease elsewhere—usually in the kidneys, heart or in connection with the liver circulation. Obstructed portal circulation is the commonest cause of well-marked ascites. It may be confused with encysted fluids or with inflammatory exudates as in tuberculosis.

Ascites is produced by (1) diseases within the liver, as cirrhosis and cancer; (2) diseases outside the liver, as cancer of the stomach, duodenum or pancreas, causing pressure on the portal vein, or enlarged glands in the fissure of the liver. Ascites is one of the late symptoms in the disease and precedes dropsy of the legs which may come on later due to abnormal pressure on the large veins in the abdominal cavity. In ascites due to heart disease the dropsy of the feet and legs precedes the ascites, and there will be a history of palpitation, shortness of breath and perhaps cough. In the ascites of kidney troubles there will be a history of general edema including puffiness of the face and eyes on rising in the morning. (F. L. A.)

ASCLEPIADES of Bithynia, Greek physician, was born at Prusa in Bithynia (modern Bursa, Turk.) in 124 B.C., and flourished at Rome about the end of the 2nd century B.C. He traveled

much when young, and seems at first to have settled at Rome as a rhetorician. In that profession he did not succeed, but he acquired great reputation as a physician.

He founded his medical practice on a modification of the atomic or corpuscular theory, according to which disease results from an irregular or inharmonious motion of the corpuscles of the body. His remedies were directed to the restoration of harmony, and he trusted much to changes of diet, accompanied by friction, bathing and exercise, though he also employed emetics and bleeding. He recommended the use of wine. His pupils were numerous, and the school formed by them was called the Methodical. He is stated to have been the first to use music in the treatment of the insane. Asclepiades died at an advanced age.

ASCLEPIADES of Samos (fl. *c.* 270 B.C.), was the earliest and most important of the Alexandrian epigrammatists. He is given as the author of about 40 poems in the Greek anthology, mainly love songs, and was probably the first to introduce into poetry such symbols as Love the archer. A friend of Theocritus, he was addressed by him under his pen name of Sicelidas.

See J. W. MacKail, *Select Epigrams From the Greek Anthology*, with trans (1911).

ASCLEPIUS (Asklepios; Lat. Aesculapius), the Greek god of medicine, the son of Apollo and the nymph Coronis. He probably came from Thessaly. The centaur Chiron taught him the art of healing. At length Zeus, being afraid that he might render all men immortal, slew him with a thunderbolt.

Homer, in the *Iliad*, mentions him only as a skilful physician, whose sons, Machaon and Podaleirius, are physicians in the Greek camp before Troy. In later times, however, he was honoured as a hero—for example, at Athens—and eventually worshiped as a god. The cult began in Thessaly, but temples were erected to Asclepius in many parts of Greece, near healing springs or on high mountains. The practice of sleeping in these sanctuaries was very common, it being supposed that the god effected cures or prescribed remedies to the sick in dreams (*cf.* the modern practice in the Aegean island Tenos, cited by M. P. Nilsson in *History of Greek Religion*, p. 300 [1925]). All who were healed offered sacrifice (especially a cock), and many tablets, recording their names their diseases and the manner in which they had been cured, have been discovered at Epidaurus (*q.v.*), the god's most famous shrine. Herodas, in his fourth mime, gives a description of one of Asclepius' temples and of the offerings made to him. Festivals in honour of Asclepius are known to have been observed in cities as widely separated as Ancyra in Asia Minor and Agrigentum in Sicily. The cult was introduced to Rome by order of the Sibylline books (293 B.C.), to relieve a pestilence. A delegation sent to fetch the image of the god from Epidaurus returned bringing instead a snake in which the god was thought to reside. A temple was assigned to him on an island in the Tiber.

Asclepius is frequently represented in ancient sculpture and as a coin type, standing, dressed in a long cloak, with bare breast; his usual attribute is a clublike staff with a serpent coiled around it. This staff with its single serpent is the only true symbol of medicine. The caduceus with its winged staff and intertwined serpents, which is frequently used in the U.S. as a medical emblem, is without medical relevance since it represents the magic wand of Hermes or Mercury, the messenger of the gods and the patron of trade. Asclepius is often shown accompanied by Telesphorus, the boy genius of healing, and his daughters, Hygieia, the goddess of health, and Panacea. Votive reliefs representing such groups have been found near the temple of Asclepius at Athens. His extremely popular cult yielded late and slowly to Christianity.

(T. V. B.)

ASCOLI, GRAZIADIO ISAIA (1829–1907), Italian linguist, a pioneer in dialect studies, was born on July 16, 1829, in Gorizia. Without formal higher education, he wrote his first major work in 1854 on oriental languages. He was professor at Milan from 1860 to 1907. His contributions in Indo-European, Celtic and Romanic linguistics were notable, but he is mainly known for his work in dialectology. In 1873 Ascoli founded the journal *Archivio glottologico italiano*, which he edited until 1907. In vol. i he published "Saggi ladini" on the previously neglected Raeto-Romanic dialects; in vol. viii appeared his "Italia dialettale," a model classification of Italian dialects. He emphasized the importance of studies of living vernaculars. He rejected, as a matter of method, the tenets of the neogrammarian school concerning sound laws. Ascoli was greatly honoured during his lifetime. He died in Milan on Jan. 21, 1907. (E. Pm.)

ASCOLI PICENO, a city and province of the Marches, central Italy. The provincial capital, Ascoli Piceno lies among wooded hills (chiefly oaks and chestnuts) about 500 ft. above sea level at the confluence of the Tronto and Castellano rivers, which surround it on the north, east and south, 130 mi. N.E. of Rome by road. Pop. of commune (1961) 50,125. Two of the main streets correspond with the old Roman thoroughfares and there are remains of the Roman city wall (4th to 2nd centuries B.C.) as well as much of the medieval wall. There are two Roman bridges, one of which was partly destroyed by the Germans in 1944, and remains of a theatre, an amphitheatre, a capitol and a temple of Vesta. With the introduction of Christianity (*c.* 300) pagan temples became churches and later Benedictine cloisters were built. In 1006 the civil power passed to bishops and feudatories but internal quarrels caused fortifications to be built, including numerous towers, a few of which still stand, mostly truncated or incorporated in houses. Defense at this period involved much destruction with the consequent formation of slums, many of which remain. The medieval castle, high on the hill, was largely destroyed in 1798 and the fortress of Malatesta (1349) is now a prison.

In 1245 St. Francis constituted his Order in Ascoli, and the great Gothic church dedicated to him was built in 1265. The cloisters are now the market place. The Palazzo dell'Arrengo and the Palazzo del Popolo (now a museum) date from the end of the 13th century. After 1300 the town declined from loss of trade and internal strife. The cathedral, founded between the 8th and 12th centuries, was enlarged between 1481 and 1592. Carlo Crivelli (*q.v.*) started an artistic movement in the town about 1486. Ascoli Piceno contains a picture gallery, a public library (opened 1856) with incunabula, early printed books, manuscripts and parchments, and a museum (founded 1779). The chief industries are agricultural, but there are chemical and electrical works and other smaller businesses.

Known to the Romans as Asculum Picenum, the ancient city was captured by them in 268 B.C. during the building of the Via Salaria. It played a leading part in the Social War against Rome; the praetor C. Servilius provoked a massacre of the Romans there in 90 B.C. but P. Strabo besieged and took it in 89 B.C. Caesar occupied Asculum after crossing the Rubicon and later it became the capital of Picenum (*q.v.*). It was captured by Totila in A.D. 545. In 781 Charlemagne gave Ascoli to Pope Adrian I and it was made a Papal state; in 1183 it became a republic with free judicial administration. It was taken by Frederick II in 1242 but in 1266 it again became a papal possession, keeping some of its former rights, and entered a period of great prosperity. Under French domination from 1798 to 1815 it returned to papal jurisdiction after the fall of Napoleon and became part of the Italian kingdom in 1860. Bridges were blown up during World War II and the town was captured by the Allies in July 1944.

ASCOT, a village of Berkshire, Eng., 6 mi. S.S.W. of Windsor, famous for its race meetings. At the Royal Meeting, held on four days in June, it is customary for the sovereign to drive down the course each day in an open carriage accompanied by members of the royal family and guests, also in carriages. The Gold Cup is one of the most important races of this meeting. The race course is on Ascot heath and was laid out by order of Queen Anne in 1711. Ascot is in the ecclesiastical parish of Ascot Heath (pop., including Sunninghill [1961], 7,799).

ASELLI (Asellio), **GASPARE** (1581–1626?), Italian phy-

sician who contributed to the knowledge of the circulation of body fluids by discovering the lacteal vessels, was born at Cremona in 1581, became professor of anatomy and surgery at Pavia and practised at Milan, where he died about 1626.

He described the lacteals (lymph vessels in the intestine that take up certain products of digestion) in *De lactibus sive lacteis venis,* which was published in 1627 just before the *De motu cordis* of William Harvey, who appears to have been unaware of Aselli's work. Earlier observations on the lacteals by the ancient Greeks and the great Italian anatomists Fallopius and Eustachius had been sporadic and without comprehension of their function and importance.

Aselli's discovery occurred in 1622 during the vivisection of a dog that had been richly fed just prior to the operation. On opening the abdomen he noticed whitish cords that exuded a creamlike liquid. Upon careful repetition of the experiment he described these new vessels as *venae albae et lacteae*.

See T. L. Pagel, *Einführung in die Geschichte der Medizin,* ed. by Karl Sudhoff, 2nd ed. (1915); Arturo Castiglioni, *A History of Medicine,* trans. and ed. by E. B. Krumbhaar (1947). (I. V.)

ASEN (Assen), the first dynasty of the second Bulgarian empire (*see* Bulgaria), founded by the brothers Asen and Peter, landowners and boyars from Turnovo, whose actual family name was Belgun. While some historians have contended that the family was of Vlach descent, it was more probably Kuman-Bulgarian in origin, but there is written evidence that the Asens considered themselves and were considered abroad as the rulers of both the Vlachs and of the Bulgars.

In 1186 after a violent dispute with the Byzantine emperor Isaac II Angelus, Asen and Peter led a popular rising of Vlachs and Bulgars and proclaimed their independence from Constantinople. Asen was crowned tsar as Ivan Asen I at Turnovo, and Peter became ruler of the eastern half of the kingdom, with his residence at Preslav. The brothers invaded Thrace but were defeated, withdrew to the north and, in alliance with the Kumans, conquered northern Bulgaria. In 1187 they checked the imperial army in Thrace and, in the armistice that followed, their younger brother Kaloyan was sent as hostage to Constantinople. He escaped, however, and war broke out, to continue intermittently until the Byzantine forces were thoroughly defeated in 1196. Later in that year Ivan Asen was killed by one of his boyars, Ivanko, who seized power at Turnovo but soon had to seek refuge in Constantinople. Asen's brother Peter ascended the throne but was killed by the boyars in 1197. Kaloyan was then crowned tsar. A shrewd and capable ruler, but violent and cruel, he restored and consolidated his power over northern Bulgaria and began negotiations with Rome. In Nov. 1204 Pope Innocent III's legate bestowed the title of primate of Bulgaria on the bishop of Turnovo, Basil, who then crowned Kaloyan king. With papal backing, Kaloyan now approached Baldwin I, the Latin emperor of Constantinople, but the latter refused a treaty unless Kaloyan reverted to the position of a vassal. In the war that followed, the Latins were defeated at Adrianople in April 1205. Baldwin was taken prisoner and later murdered at Turnovo. For two more years Bulgars and Kumans jointly ravaged Thrace, but in 1207, while besieging Salonika, Kaloyan was killed by one of the Kuman chiefs, probably at the instigation of the tsar's own wife. One of the accomplices, Kaloyan's nephew Boril, proclaimed himself tsar and married his uncle's widow. His incompetent and highly unpopular reign ended in 1218, when Tsar Asen's son Ivan Asen II deposed and blinded him.

Ivan Asen II was a good soldier and a man of wisdom and humanity. He restored law and order, controlled the boyars and, after defeating Theodore, despot of Epirus, in 1230, acquired large parts of Albania, Serbia, Macedonia and Epirus. The record of his achievements, dated 1230, can still be seen in the old church of the Forty Martyrs at Turnovo. One of his daughters was married to the Serbian prince Vladislav, whom Ivan was able to establish as king of Serbia; another was married to Manuel Angelus, ruler of Salonika; and his third daughter, Helen, was betrothed in 1228 to the 11-year-old Latin emperor Baldwin II. The regency of the empire was then offered to Ivan, who agreed in return to give back his conquests in Epirus, western Macedonia and Albania. The Latins, however, afraid of Bulgaria's growing power, repudiated the treaty, and Baldwin was betrothed to the daughter of John of Brienne, king of Jerusalem, who was elected emperor. Ivan Asen gave Helen to the son of the Greek emperor of Nicaea and denounced Kaloyan's agreement with Innocent III, thus separating the Bulgarian Church from Rome. During the siege of Constantinople by the Greeks of Nicaea (1236), the tsar, changing sides once more, allied himself to the Latins, but in 1237 he was finally reconciled with Nicaea and withdrew from the struggle. He died in 1241.

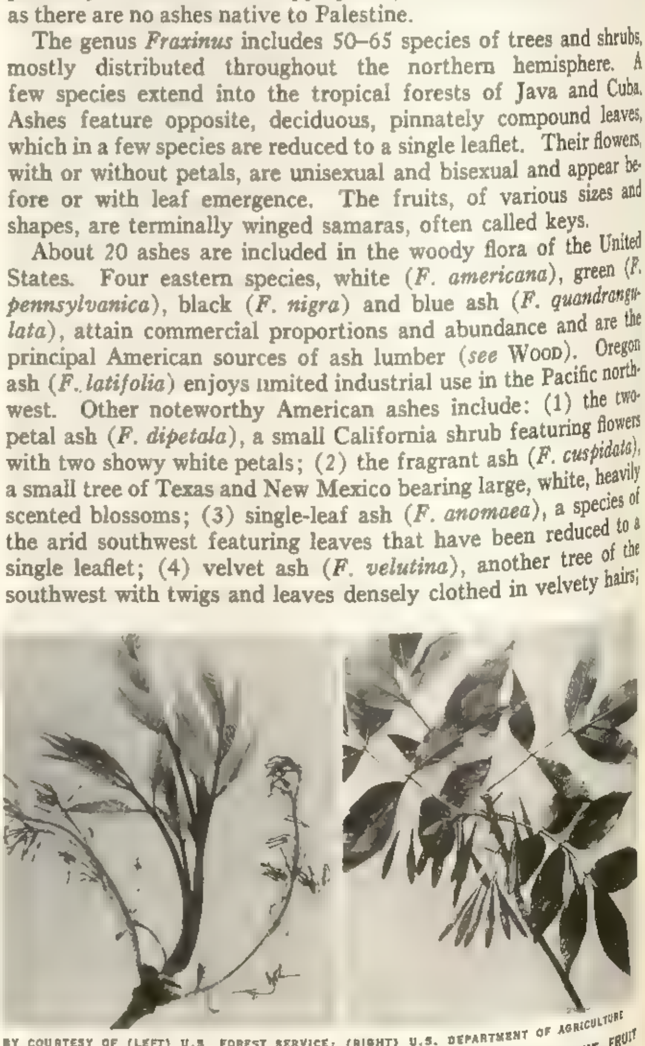
Under Ivan Asen II's sons Kaliman I (1241–46) and Michael I (1246–57), large parts of Thrace, Macedonia and Albania were lost to the Greeks of Nicaea. These reverses played into the hands of the unruly boyars. With their complicity Michael was killed by a prince of the royal blood, who was crowned under the name of Kaliman II (1257), but the boyars killed him also less than three months later. The male line of succession in the Asen dynasty now came to an end, and the Bulgarian crown passed into other hands. In 1262, however, Mitza, a nephew of Kaliman I and Michael, seized power for a short time but then had to flee to Constantinople. His son was crowned as Ivan Asen III in 1279, but a mass rising of the peasantry forced him to leave Bulgaria a few months afterward, in 1280. (N. I. M.)

ASEPSIS: *see* Antiseptics.

ASH, the common name originally applied to members of the genus *Fraxinus* of the olive family (Oleaceae). Unrelated groups, mostly with pinnately compound leaves, are also commonly known as ashes. The Hebrew word *Oren,* translated "ash" in Isa. xliv, 14, probably referred to the Aleppo pine (*Pinus halepensis*), inasmuch as there are no ashes native to Palestine.

The genus *Fraxinus* includes 50–65 species of trees and shrubs, mostly distributed throughout the northern hemisphere. A few species extend into the tropical forests of Java and Cuba. Ashes feature opposite, deciduous, pinnately compound leaves, which in a few species are reduced to a single leaflet. Their flowers, with or without petals, are unisexual and bisexual and appear before or with leaf emergence. The fruits, of various sizes and shapes, are terminally winged samaras, often called keys.

About 20 ashes are included in the woody flora of the United States. Four eastern species, white (*F. americana*), green (*F. pennsylvanica*), black (*F. nigra*) and blue ash (*F. quandrangulata*), attain commercial proportions and abundance and are the principal American sources of ash lumber (*see* Wood). Oregon ash (*F. latifolia*) enjoys limited industrial use in the Pacific northwest. Other noteworthy American ashes include: (1) the two-petal ash (*F. dipetala*), a small California shrub featuring flowers with two showy white petals; (2) the fragrant ash (*F. cuspidata*), a small tree of Texas and New Mexico bearing large, white, heavily scented blossoms; (3) single-leaf ash (*F. anomaea*), a species of the arid southwest featuring leaves that have been reduced to a single leaflet; (4) velvet ash (*F. velutina*), another tree of the southwest with twigs and leaves densely clothed in velvety hairs;



BY COURTESY OF (LEFT) U.S. FOREST SERVICE; (RIGHT) U.S. DEPARTMENT OF AGRICULTURE

WHITE ASH (FRAXINUS AMERICANA): LEFT, FEMALE FLOWERS; RIGHT, FRUIT AND LEAVES

and (5) pumpkin ash (*F. profunda*), a tree of eastern and southern coastal swamps productive of a characteristically light, weak, brash wood of little value.

Known since early Roman times, the European ash (*F. excelsior*) is a timber tree of wide distribution through Europe and Asia Minor. A number of its varieties have been cultivated and used in landscaping for centuries. Notable among these are forms with weeping and dwarflike habits, variegated foliage, warty twigs and branches, and curled leaves. One especially interesting form, *F. e. diversifolia*, which occurs naturally in England and on the continent, features simple and three-parted leaves.

Flowering ash (*F. ornus*) is a handsome tree indigenous to Europe and Asia, the saccharine exudate of its bark being the source of manna (*q.v.*) used as a mild laxative for children. A white wax is obtained from *F. chinensis*, while highly figured veneer is the product of *F. mandshurica* and *F. sieboldiana*.

The European and American mountain ashes are *Sorbus aucuparia* and *Sorbus americana*, of the rose family. The poison ash of southeastern United States is in reality poison sumac (*Rhus vernix*), a member of the Anacardiaceae and a close relative of poison ivy. Prickly ash, a shrub of eastern United States, is *Zanthoxylum americanum*, of the citrus family. *Flindersia* and *Tarrietia* are two Australian genera productive of the silver ash and crow's ash timbers, respectively. The former is a member of the citrus family (Rutaceae); the latter belongs to the Sterculiaceae, the cocoa family. Cape ash, *Ekebergia capensis*, of the Meliaceae, is indigenous to the Cape of Good Hope. (E. S. Hr.)

A'SHA (Maimun ibn Qais), Arabian poet of the 6th–7th century, famous for his description of wines, was born in Manfuha, a village of al-Yamama in the centre of Arabia, and became a wandering singer, passing through all Arabia. Born before Mohammed, he lived long enough to accept the mission of the prophet. He died *c.* A.D. 629. Even before the time of Mohammed he is said to have believed in the resurrection and last judgment and to have been a monotheist, probably under the influence of his patron, Haudha ibn 'Ali, chief of al-Yamama. Several other Arabian poets were also called al-A'sha (the "night blind").

ASHANTI, one of the regions of Ghana, was the core of the old kingdom of Ashanti which was annexed by Britain in 1902. Under the colonial regime (1902–57), the province of Ashanti also included the Brong states in the west, whose related peoples were incorporated in the Ashanti union early in the 18th century (*see* Brong-Ahafo Region).

The Ashanti (Asantefo) belong to the Akan (*q.v.*) peoples of Ghana who occupy most of the southern half of the country. The Akans speak closely related dialects known under the generic name of Twi, which is a Sudanic language of the Kwa subfamily. The dialect spoken by the Ashanti is Asante. About 80% of the people live in small towns and villages. They are predominantly agricultural, practising shifting cultivation and growing maize, manioc, plantain, bananas, yams, and coco-yam among their principal crops for the home market, and cocoa for export.

The rule of matrilineal descent is the key to Ashanti social organization. It governs titles to different offices or property and jural rights and obligations. The extended family is the basis of social as well as political life. Local communities consist of kin groups or lineages, and election to political offices is based on the lineage system. But there is also full recognition of patrilineal descent, which determines certain religious and moral obligations. Ashanti social organization is thus maintained by the recognition of maternal as well as paternal bonds and the reconciliation of their respective obligations, rights, and claims. (K. A. Bu.)

The population of Ashanti was 818,944 at the 1948 census and its area was 24,379 sq.mi. After Ghana attained independence in 1957, Brong-Ahafo region was created from Ashanti, which was reduced to 9,417 sq.mi. The Ashanti population, however, had increased by the 1960s to more than 1,100,000. The capital of the region and the headquarters of one of the eight administrative districts into which it is divided is Kumasi (*q.v.*), the seat of the *Asantehene* (king of the Ashanti). The headquarters of the other districts are Ejisu, Juaso, Offinso, Mampong, Teppa, Bekwai, and Fomena.

The Kwahu scarp, which runs across the country from northwest to southeast, divides Ashanti into two topographically distinct halves. South of the scarp is a thickly forested plateau, which is the true Ashanti country. Kumasi stands at its centre. Twenty-one miles to the southeast is the sacred Lake Bosumtwi, 5 mi. in diameter, which lies at the bottom of a remarkable craterlike depression. North of the scarp, the land is undulating savanna drained by the Volta River.

Golden Stool.—The Kingdom of Ashanti, or the Ashanti union, was one of the last and greatest of the Akan states. The focal point in its history has been its sacred golden stool, the significance of which cannot be appreciated unless some mention is first made of the nature of Akan political society. The primary political unit is the village, governed by a council of clan elders (though less significant today, at the time the Ashanti union was formed the matrilineal clan was fundamental to Akan social life) and by a headman elected by the elders for life as long as he retains their confidence. The headman's authority is not autocratic but representative and paternal. A number of villages form a state (*oman*), whose government by a chief (*omanhene*) and elders is a more elaborate replica of village government. Within each state, one clan provides the royal lineage, and a candidate for the chieftaincy is nominated by the Ashanti queen mother—who is the royal clan's authority on kinship and precedence—for election by the elders.

Ancestor worship plays a large part in Akan life, and clans and states are regarded as comprising the spirits of their dead as well as their living members. A chief is consequently more than a political head: he is the chief earthly representative of his state's and his clan's most important ancestors and the guardian of their interests. One of the principal symbols of the spiritual unity of the state existing in its chief is the latter's stool. Besides being his chair of state, the stool is the repository of his spirit or personality (*sunsum*). The ceremonially blackened stools of departed chiefs are kept in a stool house, where sacrifices are offered to the spirits they represent. Formerly the sacrifices made on important occasions were commonly human, usually slaves. The spiritual continuity of chieftainship is established when, just before taking office, a chief-elect is formally placed on his predecessor's stool for a few moments. A chief's stool may thus be said to symbolize the spiritual unity of a state, its community with its ancestors, and the position of the chief as guardian of the traditions of the state and of his predecessors. A chief may be "destooled" not only because he has lost the confidence of his people but also when he is deemed to have forfeited the trust of the ancestors.

Formation and Growth of the Union.—The original nucleus of the Ashanti union lay in a number of small states established in the forest *c.* A.D. 1600 by small groups of Akan immigrants from the west. These states paid tribute to Denkera, a more powerful Akan state to the southwest. About the middle of the 17th century, the rulers of a number of these states, who were all members of the Oyoko clan, began to cooperate under the leadership of the chiefs of Kumasi in an attempt to check the encroachments from the west of the Doma, another Akan people. When Osei Tutu became *Kumasihene* (*c.* 1680?), he and his *okumfo* (priest) Anokye enlarged this alliance and the Doma were soon decisively defeated.

Osei Tutu and Anokye then determined to free the Ashanti from dependence on Denkera. In their estimation, the existing alliance among the Ashanti states was not adequate to this task, and they determined to convert it into a permanent military union. Such a union was feasible only if they could establish a spiritual community of the whole Ashanti people transcending the particular spiritual unity of each state. Their solution was the golden stool. Tradition asserts that a wooden stool adorned with gold was brought forth from the sky by Anokye before a great assembly of chiefs and people and that it descended gently onto the knees of Osei Tutu. Anokye declared that this stool contained the *sunsum* of the whole Ashanti people and that the strength of the nation depended on its preservation. Thenceforward, since the *omanhenes* present all formally subscribed to this view, every Ashanti had a dual allegiance: to his state stool and chief, and to the golden

stool and its guardian, who was now *Asantehene* as well as *Kumasihene*. The golden stool achieved a perpetual sanctity of its own and took precedence of the *Asantehene* himself.

The union thus established duly defeated the Denkera, absorbed some of their subject states, and was drawn on into further wars against their allies in the south. Osei Tutu died in 1712, and shortly afterward his successor seems to have been killed in a war with Akim Kotoku. This disaster was revenged by Opoku Ware (*c.* 1720–50), who brought the northern Akim states and Sefwi into the union, and embarked on extensive conquests to both north and south, a policy further continued by Osei Kojo (1764–77). Thus in the north the Ashanti empire was extended over the ancient Akan state of Tekyiman, over Gyaman and Banda, and as far as Dagomba, while in the south expeditions against Wassaw and the Akim and Akwapim states brought Ashanti into contact with the coast. In 1806–07 an Ashanti army under Osei Bonsu (1800–24) invaded the Fanti states and reached the sea. The commanders of the English and Dutch forts on the coast were forced to recognize Ashanti suzerainty over the Fanti and to accept the Ashanti as landlords of their forts (*see* FANTI).

The underlying motive of these Ashanti conquests seems to have been basically economic. The defeat of Denkera enabled the Ashanti to make contact with the apparently inexhaustible market for slaves and gold afforded by the European merchants at the coast. Conquest of the coastal peoples promised closer control of this trade and its profits together with an assured supply of munitions of war, while inland expansion would provide more slaves and gold for export and a closed hinterland in which Ashanti merchants could profitably retail European goods.

The Ashanti union, however, failed to evolve a mechanism of government for the states it conquered. It assumed that the relation of their rulers to the *Asantehene* would be the same as that of the rulers of the original member states, but the conquered states had spiritual personalities and traditions of their own. Their allegiance was in part a result of the military expediency and economic advantage of siding with the conquering power. But even while the Ashanti were demonstrating this power in the coastal states, its fundamental premises were being destroyed. Between 1804 and 1814 the three European countries whose merchants possessed forts on the Gold Coast—Great Britain, Holland, and Denmark—all outlawed the slave trade for their subjects. Though the Danes and the Dutch gradually lost interest in the coast, the British remained. Their merchants wished to substitute legitimate trade for the trade in slaves, while their government gradually committed itself to the task of abolishing the whole African slave trade and of encouraging the peaceful progress of African peoples. In the Gold Coast this involved first the establishment of a peaceful modus vivendi with Ashanti and eventually responsibility for the protection and government of the coastal peoples among whom the European merchants lived and, therefore, for the ultimate defeat of Ashanti.

Early Contacts with the British.—In 1817 the English merchants negotiated a treaty with Osei Bonsu under which the former were held responsible for the good behaviour of the Fanti states. This led to difficulties; and when in 1821 the British government took over the British forts, the new governor, Sir Charles MacCarthy, organized the coastal peoples to resist Ashanti pressure. In 1824 MacCarthy's forces were defeated and he himself was killed, but two years later the British and their allies routed a new Ashanti invasion. By a peace treaty in 1831 the Ashanti agreed to keep the peace and recognized the independence of Denkera, Akim and Assin, and British and Danish sovereignty in the forts (*see* also BOWDICH, THOMAS EDWARD).

The period from 1831 to 1843 was one of peace and prosperity during which British influence with the coastal peoples steadily increased. But the peace was humiliating to Ashanti, whose expansion had suffered its first major reverse and whose market for slaves was steadily diminishing (with the result that the practice of human sacrifice was on the increase). After 1843 misunderstandings between Ashanti and the local British authorities became increasingly frequent and bitter. Since the British were now clearly the paramount coastal power, the Ashanti held them responsible for the good behaviour of the coastal peoples. But Great Britain's legal relation to the coastal states before 1874 was at most that of a protecting power, and the British authorities did not accept responsibility for the coastal peoples in disputes with Ashanti or for returning to Kumasi fugitives from Ashanti justice.

Great Britain and Ashanti drifted into a hostility which became open in 1863. At first there was little direct conflict, the Ashanti for the most part contenting themselves with expeditions against their immediate neighbours to the south and southeast. In 1869, however, an Ashanti army in Togoland captured a party of German missionaries, and in 1870 the *Asantehene* Kofi Karikari protested against the transfer of the fort at Elmina from the Dutch to the British on the ground that he was still its overlord. In 1873 a full-scale Ashanti offensive was launched toward the coast, and the Denkera and Fanti were soon heavily defeated. The British government was at last convinced of the need for firm action.

Maj. Gen. Sir Garnet (later Viscount) Wolseley (*q.v.*) was sent out as governor and commander in chief, British troops led an invasion of Ashanti, and in Feb. 1874 Kumasi was captured and destroyed.

But, though in 1874 the British finally accepted responsibility for the government of the coastal states, they had no intention of occupying Ashanti. All they wanted was to destroy the Ashanti threat to their coastal colony, and in 1874 it seemed as though this had been achieved. The Ashanti union was breaking up under the stress of defeat, and each of the member states adhered separately to the treaty of Fomena (1874), by which the Ashanti renounced all claims to Denkera, Akim, Assin, Adansi, and the coastal forts; and promised to trade peaceably, to abandon the practice of human sacrifice, and to pay an indemnity. But in the same year, Kofi Karikari was destooled, and his successor, Mensa Bonsu, devoted himself to the reconstruction of the union. The Ashanti states proper were soon restored to their old allegiance, as were some of the more central non-Ashanti states. To go further might have led to further hostilities with the British since some of the remoter former members of the union were now under British influence. Mensa Bonsu shrank from this risk, with the result that he too was destooled (1883). After a period of uncertainty and civil war during which different factions struggled for supremacy in Ashanti, Prempeh, a youth 16 years old, was enstooled in 1888. His authority had been forcibly established throughout the union by 1893.

The British Protectorate and Colony.—The British viewed the events of these years with some mistrust, but failed to adopt any positive policy toward the country until after Prempeh and his party were firmly in control. Eventually in 1895 the Ashanti were charged with failure to observe the terms of the Fomena treaty and required to accept a British protectorate. When the Ashanti tried to negotiate, the British couched their demands in the form of an ultimatum and, early in 1896, occupied Kumasi for the second time. Prempeh and the leading chiefs and members of the royal line were deported to the Seychelles. The Ashanti union was considered dissolved, and its member states were brought under British protection by a series of separate treaties.

The four years 1896–1900 saw an uneasy vacuum in Ashanti. The nation's leaders were exiled, the union was broken, and the golden stool hidden away. The people were sullen and resentful of a power that seemed to have destroyed their nation without actually conquering it. The British failed to understand the situation and, although they maintained a resident in Kumasi, provided neither leadership nor effective administration. During a visit to Kumasi in 1900, the governor of the Gold Coast, Sir Frederic Hodgson, declared that it was an insult to the queen whom he represented that he was not sitting on the golden stool.

CHARLES MAY FROM BLACK STAR

FORT AT KUMASI IN WHICH BRITISH FORCES WERE BESIEGED IN 1900

The Ashanti were scandalized; three days later a whole nation had risen against the British, and Hodgson and his retinue were besieged. Nine months of bitter fighting followed before the British were again in control.

On Jan. 1, 1902, in pursuance of an order in council of Sept. 26, 1901, Ashanti was formally declared a British colony. The country was administered autocratically by the governor of the Gold Coast through a chief commissioner in Kumasi and a number of district commissioners. Direct European rule, together with the social changes resulting from European education and Christian missions, the building of railways and roads, and the development of a cash-crop economy seriously undermined the prestige of the traditional authorities. British rule allowed little effective power to the chiefs, and the people appreciated that such power as was left to them derived from the British government. Destoolment of chiefs became increasingly frequent.

The first British attempt to understand the social and political organization of Ashanti came with the appointment of Capt. R. S. Rattray as government anthropologist in 1920. Rattray was just in time to advise on the policy to be pursued when a few Ashanti accidentally found the hiding place of the golden stool and robbed it of its golden ornaments. In Ashanti eyes the crime was sacrilege punishable only by death. British authority allowed the crime to be investigated by a council of Ashanti chiefs but could not allow the council the status of a court of law; the ultimate sentence for those found guilty was deportation.

The Confederacy Council.—During the 1920s British administration in the Gold Coast as a whole began to move toward indirect rule. In Ashanti, guidance was afforded by Rattray's elucidation of the socially cohesive value of the old authorities. In 1924 chiefs were given definite powers of subordinate jurisdiction, and Prempeh was brought back (he was officially recognized, though as *Kumasihene* merely, in 1926). In 1935 his successor, Prempeh II, was restored to the dignity of *Asantehene*, and an Ashanti confederacy council was recognized by law. But the break with the past had been made, and by the 1960s it was clear that the golden stool could not recapture its former significance. For administrative, economic development and later history of Ashanti *see* GHANA.

ASH'ARI, AL- (ABU 'L-HASAN 'ALI AL-ASH'ARI) (873–935), Arabian theologian, was born of pure Arab stock in Basra but spent the greater part of his life in Baghdad. He is said to have been a pupil of the Mu'tazilite (rationalist) teacher al-Jubba'i and to have remained a Mu'tazilite until his 40th year, when he was converted to traditional Islamic orthodoxy. His name was in later times attached to the school of orthodox theologians who admitted the validity of reason and created the scholastic theology of Islam, which became dominant among the Shafi'ites. He is said to have written about 300 works, of which only four or five are known to be extant. The most remarkable of these is the *Makalat al-islamiyin*, in which the Muslim sects and heresies are examined and the orthodox creed is set forth.

See also ARABIC PHILOSOPHY; ISLAM.

Klein (1940). *See* also *The Theology of al-Ash'ari*, texts, translations and appendices ed. by R. J. McCarthy, S. J. (1953); A. J. Wensinck, *The Muslim Creed* (1932); A. S. Tritton, *Muslim Theology* (1947).

ASHBOURNE, an urban district of Derbyshire, Eng., lies 13 mi. WNW of Derby by road on rising ground between two small ravines opening into the valley of the Dove. Pop. (1961)

5,660. Area 1.7 sq.mi. Ashbourne is a marketing centre for the surrounding agricultural districts, and also for fishermen and tourists visiting the scenic Dovedale and Manifold Valley. The church of St. Oswald, dating from 1241, is a cruciform building with a central tower and lofty octagonal spire (212 ft.) and contains brasses and monuments to the Bradbourne, Cockayne, and Boothby families. In Ashbourne Hall, until 1671 the seat of the Cockaynes and from then until 1847 of the Boothbys, Prince Charles Edward stayed in 1745. The oldest of the famous almshouses was founded in 1640. There are many associations with Samuel Johnson, a frequent visitor to John Taylor who occupied the mansion (now the girls' boarding house for the grammar school) opposite the old grammar school (built 1586, now the boys' boarding house). The present school building was built in 1909. The free-for-all traditional Shrovetide football game between Up'ards and Down'ards is still played; the goals are three miles apart. The making of corsets, condensed milk, clocks, and fishing tackle (since 1763) are the chief industries.

ASHBURNHAM, JOHN (*c.* 1603–1671), English royalist, who served Charles I from 1628 as a groom of the bedchamber, is remembered chiefly for his part in persuading the king, on his escape from Hampton Court in 1647, to go to the Isle of Wight rather than abroad. The son of Sir John Ashburnham, who died in 1620, he began a career at court under the patronage of George Villiers, 1st duke of Buckingham. He was treasurer of the Royal Army during the Civil War and commissioner in the Uxbridge negotiations (1644) and then went abroad. After the seizure of Charles I by the army, Ashburnham joined him at Hampton Court in 1647. The king chose wrongly in following Ashburnham's advice, in opposition to that of Sir John Berkeley, to make his escape to the Isle of Wight. In so doing, he placed himself in the hands of Robert Hammond, the governor, before the latter's loyalty had been ascertained. "Oh, Jack," the king is alleged to have exclaimed when he understood the situation, "thou hast undone me!" By this fatal step Ashburnham incurred the unmerited charge of treachery and disloyalty, but of this he was acquitted both by Charles I and Charles II. He was separated, with Berkeley, from Charles on Jan. 1, 1648, and in May was imprisoned at Windsor. In Aug. 1648 he was exchanged for Sir W. Masham, but the same month Charles I's request for his attendance at the treaty negotiations at Newport was rejected, and in Oct. 1648 he was among those marked out by Parliament as "delinquents who shall expect no pardon." After Charles I's death he remained in England, an object of suspicion to all parties, corresponded with Charles II and underwent several terms of imprisonment in the Tower of London and in Guernsey. At the Restoration he was reinstated in his former place of groom of the bedchamber and was compensated for his losses. He represented Sussex in Parliament from 1661 till his expulsion, in 1667, for taking a bribe from French merchants for landing their wines. He died on June 15, 1671.

His grandson John (1656–1710) was raised to the peerage in 1689; this John's descendant Bertram (1797–1878), the 4th earl of Ashburnham, was the collector of the famous Ashburnham Library.

ASHBURTON, JOHN DUNNING, 1st Baron (1731–1783), English lawyer, is chiefly remembered as author of the motion that the "influence of the crown has increased, is increasing, and ought to be diminished," which he brought forward in the house of commons in 1780. He was born at Ashburton, in Devon, on Oct. 18, 1731, and was called to the bar in 1756. In 1762 he was employed to draw up a defense of the British East India Company against the Dutch East India Company, which had memorialized the crown on certain grievances. This masterly document immediately procured him reputation and emolument. In 1763 Dunning distinguished himself as counsel for John Wilkes (*q.v.*), whose case he conducted throughout. His powerful argument in the case of *Leach* v. *Money* (June 18, 1764) established his reputation, and his practice from this period gradually increased. In Jan. 1768 he was appointed solicitor-general, probably under the particular patronage of Lord Chancellor Camden. His friend Lord Shelburne brought him into Parliament in 1768 as member for Calne, which he represented till 1782. He disapproved of the government's further proceedings against Wilkes, which Camden and he both criticized in Parliament in Jan. 1770. On Camden's consequent dismissal he immediately resigned. From this period he was considered as a regular member of the opposition. His motion against the crown in 1780 was carried by a majority of 18. He strongly opposed the system of sinecure offices and pensions; but in 1782, when the marquis of Rockingham became prime minister, Dunning was raised to the peerage and appointed chancellor of the duchy of Lancaster, a rich sinecure. Under Shelburne's administration he accepted a pension of £4,000 a year. He died at Exmouth on Aug. 18, 1783.

(I. R. C.)

ASHBURTON, an urban district and market town in Devon, Eng., lies 20 mi. SW of Exeter and 22 mi. NE of Plymouth by road. Pop. (1961) 2,722. It lies under the southeastern edge of Dartmoor, in the valley of the Ashburn near its confluence with the Dart. Ashburton was a borough by prescription from the early Middle Ages until 1835. Since Saxon times the court leet has elected annually a portreeve (chief officer), a bailiff, and officers such as ale tasters and bread weighers. Ashburton was made a stannary (tin-mining) town by Edward I in 1285. In 1314 Bishop Walter de Stapledon gave the town the chantry chapel of St. Lawrence, whose priest was to keep a "free scole." Henry VIII suppressed the chantry in 1535, but in 1594 the chapel property was bought back from the crown and a grammar school was founded, which continued until 1938. Only the tower remains of the original chapel but an addition was made in the 17th century and it is there that the portreeve is elected. The parish church of St. Andrew, with its 92-ft. tower, was built of granite in the 15th century. The monks of nearby Buckfast Abbey (*see* Buckfastleigh) made Ashburton serge famous in the 16th century but the chief industry is now the tourist trade. (G. M. Mo.)

ASHBURTON RIVER, a stream rising in the Opthalmia range and flowing (when it does flow) for about 400 mi. to fall into the Indian ocean a little north of Exmouth gulf on the extreme western coast of Australia. This area has the greatest rainfall variability of Australia; the mean deviation from the average is over 40% and total annual rainfall has ranged from 1 to 27 in. It also has extremely high temperatures, over 100° F having been recorded for 28 successive days at Onslow. Only after exceptional cyclonic storms ("willy-willies") is "river" more than a courtesy title; it is usually dry more than three miles from its mouth, though in high flood it may be several miles wide. There is some fairly good pastoral country along the length of the river.

(O. H. K. S.)

ASHBY-DE-LA-ZOUCH, an urban district and market town of Leicestershire, Eng., lies in a fertile valley 17 mi. NW of Leicester by road. Pop. (1961) 7,460. Coal seams surrounding Ashby are worked by both deep and opencast mining. Other industries include soap and biscuit making, limestone quarrying, and engineering. There are weekly markets and stock sales. The suffix "de-la-Zouch" was given to Ashby by Alain de Parrhoet la Souche, lord of the manor in the 12th century. In 1461 the manor was granted by Edward IV to Sir William Hastings who became Baron Hastings and whose grandson was created earl of Huntingdon in 1529. Sir William obtained royal licence to enclose land and to build a fortress. Besieged in 1644, this castle surrendered to the parliamentarians in 1645 and was largely demolished in 1648. After the publication of Sir Walter Scott's *Ivanhoe* (1820), in which the castle plays a large part, the 1st marquis of Hastings took measures for the preservation of its ruins. The Perpendicular church of St. Helen contains a finger pillory and monuments to the 2nd earl of Huntingdon (1561) and to the 9th earl (1746), whose wife, Selina, founded a sect of Calvinistic Methodists known as the Countess of Huntingdon's Connexion. The 3rd earl founded the grammar school in 1567.

ASHDOD (Isdud, modern Ashdod Gimel), an ancient city in Israel about 3 mi. inland from the Mediterranean and about equidistant (18 mi.) from Gaza and from Tel Aviv. Pop. (1961) 4,604. Ashdod stands close to a large hillock of red sand (17[illegible] ft.), probably Mt. Azotus on which Judas Maccabaeus fell (1 Macc. ix, 15 ff.). Behind it, extending to the shore cliffs, lie sand

dunes under which the ancient city is probably buried.

Ashdod was an important city of the Philistine Pentapolis and a centre of the worship of Dagon. In Josh. xv it is assigned to the tribe of Judah. The Philistine conquest of Israel resulted in the capture of the Ark of the Covenant, which remained in Ashdod for a time. In the 8th century B.C. Uzziah, king of Judah, seized Ashdod, and soon afterward the city fell into Assyrian hands. In 713 Ashdod joined Egypt against Assyria, but Sargon II reduced the city to submission (Isa. xx, 1). By 701 it again had a native ruler, but Sennacherib's conquest of Tyre (700 B.C.) brought the submission of Ashdod to Assyria again, and the city paid tribute to Esarhaddon and Ashurbanipal. During the second half of the 7th century B.C. the city is said to have withstood a siege of 29 years by Psamtik II of Egypt (Herodotus ii, 157). The inhabitants of the province of Ashdod were opposed to the Jewish refortification of Jerusalem at the time of the return (Neh. iv, 7), and Nehemiah cursed the Jews who had married women of Ashdod whose children could speak only a mixture of languages (Neh. xiii, 23 ff.). Ashdod was captured and cleansed of idolatry by Judas Maccabaeus in 163 B.C., and later (148) it was taken by Jonathan, who burned the temple of Dagon. From the 4th to the 6th century A.D. it was the seat of a Christian bishopric. By the time of the crusades the city was reduced to a small village.

A modern seaport, planned to be Israel's largest, has been built on the site of three ancient ports, Ashdod-yam, Minat Isdud, and Nebi-yunis, which served the inland city of Ashdod. A team of Israeli and U.S. archaeologists conducted three archaeological campaigns, in 1962, 1963, and 1965, at ancient Ashdod, confirming Philistine occupation and identifying remains from the Early Bronze Age through the Byzantine period. Excavations showed that the city began to flourish in the late 16th century B.C. under the Egyptian monarchs of the New Kingdom. (J. S. I.)

ASHER, a tribe of Israel, called after the son of Jacob and Zilpah, Leah's maid (Gen. 30:12 ff.). The district held by this tribe bordered upon Naphtali, and was north of Issachar and Zebulun, and south of Dan. *See* TWELVE TRIBES OF ISRAEL.

ASHER BEN YEHIEL (known as ROSH) (*c.* 1250–1327), Jewish rabbi and codifier, was born in the Rhine District, but, endangered by the persecutions inflicted on the German Jews in the 13th century, he fled to Spain, where he was made rabbi of Toledo. A disciple of Meir of Rothenburg, Asher found his sole interest in the Talmud. He was a man of austere piety, profound and narrow, a determined opponent of the study of philosophy and thus antipathetic to the Spanish spirit. His *Compendium,* compiled between 1307 and 1314 and printed in most editions of the Talmud, differs from previous *compendia* in greater simplicity and in the deference shown to German authorities.

Asher was the father of the codifier Jacob ben Asher (*q.v.*).

ASHEVILLE, a city of North Carolina, U.S., and seat of Buncombe County, in the Appalachian Mountains, is about 119 mi. W of Charlotte, at the junction of the French Broad and Swannanoa rivers. It has long been the cultural, resort, and economic centre of the mountainous counties of the western part of the state. Adjacent to the Blue Ridge Parkway, Asheville is the eastern gateway to Great Smoky Mountains National Park and the Cherokee Indian Reservation. Mt. Mitchell (6,684 ft.), the highest peak east of the Mississippi River, is nearby. The city has a mild climate and is on an uneven plateau averaging 2,200 ft. in elevation. The area is cut by streams and ringed by the higher Blue Ridge, Pisgah, and Newfound Mountains.

Asheville is strategically located at a natural gap through the mountains. The area, which had been Indian territory, was settled after the American Revolution. The first settler was John Burton, who in 1794 laid out a town tract of 21 ac. and named it Morristown in honour of Robert Morris, financier of the Revolution. It was renamed Asheville for Samuel Ashe, then governor of North Carolina, and incorporated in 1797.

Asheville remained a small village until the Western North Carolina Railroad came in 1880, but even before that time the area was widely known as a health resort. The town was chartered as a city in 1883; adopted a commission form of government in 1905; and the council-manager form in 1931. Industries include textiles, paper, cellophane, electric components, wool, minerals, and tobacco.

Millionaire George Vanderbilt, at the turn of the century, built a palatial French château, Biltmore House, on his estate and in 1913 E. W. Grove, a St. Louis manufacturer, built the Grove Park Inn. Asheville also is the site of Pack Memorial Library, holding the Sondley and the Thomas Wolfe collections; and the Thomas Wolfe Memorial, the birthplace of the author. Pop. (1960) 60,192; standard metropolitan statistical area (Buncombe County), 130,074. For comparative population figures *see* table in NORTH CAROLINA: *Population.* (D. J. WR.)

ASHFORD, an urban district in the Ashford parliamentary division of Kent, Eng., 14 mi. SW of Canterbury by road. Pop. (1961) 27,996. It lies on a slight hill in the plains under the downs near the confluence of the upper branches of the Great Stour, and is a considerable road and rail centre. Ashford (Essetesford, Essheteforde) was held at the time of Domesday Book by Hugh de Montfort. A Saturday market and an annual fair were granted to the lord of the manor in the 13th century, and further annual fairs were granted by Edward III and Edward IV. Jack Cade led his men from Ashford in the rebellion of 1450. The cattle trade increased from the latter half of the 18th century because of the fertile pasture land in Romney marsh, and a stock market was established in 1784. The fine Perpendicular church of St. Mary has a lofty tower and many interesting monuments. At nearby Bethersden marble quarries were formerly worked extensively, supplying stone for Canterbury and Rochester cathedrals. Ashford has agricultural implement works, brickyards and breweries, large locomotive and carriage works, and a bicycle industry. The parishes of Kennington and Willesborough were added to the urban district in 1934.

ASHI (*c.* 352–427), head of the Jewish academy at Sura, Babylonia, and one of the two chief editors of the Babylonian Talmud. Under his leadership, the Sura Academy was revived and the gigantic task of collating the scattered notes, sayings, legislative opinions, and homiletic lore was conducted for more than 30 years. After an interruption of several decades, this work was completed by a staff of scholars, headed by Rabina, who directed the Sura Academy in the years 489–500. *See* TALMUD.

See J. Zuri, *Rab Ashi* (1924).

ASHIKAGA, the name of a family that held the title of shogun (military ruler) in Japan from 1338 until 1573, with its capital at Kyōto. The position of the family was established by Takauji (1305–1358), who in 1333 shifted his allegiance from the Kamakura military government to the rebel forces led by the retired emperor Go-Daigo (Daigo II). Go-Daigo rewarded him with landed estates, but he aspired to the title of shogun. After two years of war, Takauji entered Kyōto as a conqueror, declared that Go-Daigo had forfeited his throne, and installed another imperial relative in his place. Thereafter two emperors reigned at the same time: the southern dynasty, so-called because Go-Daigo had retired to the south of Kyōto; and the northern dynasty supported by Takauji and his successors. The schism was terminated in 1392 by the compromise of alternate reigns, although in fact the northern line prevailed.

The Ashikaga family held the title of shogun until 1573, but no shogun ever exercised effective control over all the military leaders and powerful Buddhist monasteries of the land. From 1467 on, civil wars were chronic throughout Japan, and strong feudal lords on occasion drove Ashikaga shoguns out of Kyōto. The last shogun, Ashikaga Yoshiaki (1537–1597), lost his power to his protector, Oda Nobunaga, in 1573. Some of the Ashikaga shoguns achieved fame as patrons of Zen monks who gave particular Japanese form to Chinese arts, as in the case of nō drama, landscape painting, flower arrangement, and the tea ceremony. *See* also JAPAN: *History.* (GE. M. B.)

ASHINGTON, an urban district, in the Morpeth parliamentary division of Northumberland, Eng., 26 mi. N of Newcastle upon Tyne by road. Pop. (1961) 27,304. The district along the river Wansbeck is not without beauty, but there are numerous collieries, one claiming to be the largest in the world, to which the development of the town is due. Associated with the coal

mines, there are some metal foundries. At Bothal on the river (from which parish that of Ashington was formed) is the castle that belonged to the Bertram family in the reign of Edward III. The church of St. Andrew there has Early English to Perpendicular work, and nearby is a ruined chapel of St. Mary.

ASHKENAZIM, the Jews whose ancestors in the Middle Ages lived in German lands and migrated from there to eastern and western Europe and, in the 19th and 20th centuries, overseas. *See* SEPHARDIM, ASHKENAZIM, AND ORIENTAL JEWS.

ASHKHABAD (POLTORATSK from 1919 to 1927), capital of the Turkmen Soviet Socialist Republic, U.S.S.R., since 1924, is situated in the Ashkhabad oasis at the foot of the Kopet Dag about 25 mi. from the Iranian frontier and 325 mi. E.S.E. of Krasnovodsk. Pop. (1959) 169,935. It was founded by the Russians in 1881 as a fort and as capital of the Transcaspian province. It is a station on the Krasnovodsk-Tashkent railway line and an important centre of light industry: there are silk-spinning (of national importance), yarn-spinning, knitting and shoe factories. Food industries include bakeries, meat-packing plants, wineries and candy factories. There is an important factory making windows and glassware. An oil pipeline connects the city with Krasnovodsk.

Ashkhabad is in an earthquake area and a serious tremor occurred in 1948 destroying a large part of the town which has been rebuilt on the same radial plan as before. New public buildings include two theatres, a railway station and a hotel. Higher educational establishments include the Turkmenian A. M. Gorky State university (founded in 1950 with faculties of philology, history and law, physics and mathematics, biology and geography, engineering and physical education). The Turkmen academy of sciences was founded in 1951 from the branch U.S.S.R. academy, and the permanent South Turkestan Archaeological expedition is a division of its department of social sciences. There are specialized middle schools, three theatres and four museums.

Until May 1959 Ashkhabad was also the administrative centre of an *oblast* of the same name, which absorbed the former *oblast* of Krasnovodsk in 1947 and occupied the whole southwestern part of the republic. This *oblast* has now been abolished. The Tedzhen, Kirovsk and Serakhs *raions* were transferred to the Mary *oblast* but this was abolished in 1962 and all *raions* are directly administered from Ashkhabad. (G. E. WR.)

ASHLAND, a city of Boyd county, Ky., U.S., on the Ohio river, 125 mi. S.E. of Cincinnati, just below the mouth of the Big Sandy river. A deep harbour extends the full length of the city's waterfront. Pop. (1960) 31,283; Huntington-Ashland standard metropolitan statistical area (*see* HUNTINGTON), 254,780. (For comparative population figures *see* table in KENTUCKY: *Population.*) In the early years of Kentucky and Ohio settlement thousands of pioneers drifted their flat boats past this spot without stopping. Settlers from Virginia arrived in 1815. Ashland was founded in 1850, and named for Henry Clay's estate in Lexington. Ashland was incorporated as a city in 1870, and has had a council-manager form of government since 1950.

The city stands at the mouth of the narrow but fertile Big Sandy valley which penetrates deep into the eastern Appalachian range. At one time most of the traffic into the isolated highland corners of Kentucky, West Virginia and Virginia started from this point. Subsequently the great log run from the mountains terminated at Catlettsburg and Ashland. Ashland became important, however, as the centre of the early Kentucky iron industry. The Bellefonte furnace was a large producer of iron in the 19th century, and it consumed most of the available timber for several miles about the town. Ashland was linked to central Kentucky and Cincinnati in the early 1900s by the Chesapeake and Ohio railroad, and by 1920 it had begun a new phase of economic development becoming one of the state's most important industrial centres. In the Ashland-Ironton (Ohio)-Kenova-Huntington (West Virginia) region are important iron, metal working, chemical and petroleum industries. (T. D. C.)

ASHLEY, SIR WILLIAM JAMES (1860–1927), English economist and historian of English economic development, was born in London on Feb. 25, 1860, and educated at St. Olave's Grammar School and Balliol College, Oxford. He was successively professor of political economy and constitutional history in Toronto University (1888), professor of economic history at Harvard University (1892), professor of commerce and finance in Birmingham University (1901), and dean of the faculty of commerce there (1902).

Ashley made most important contributions to the history of English industry and the economic development of England in general in his *Early History of the English Woollen Industry* (1887) and his *Introduction to English Economic History and Theory* in two parts. The *Introduction* remained for many years the standard work on the subject and was translated into German, French, and Japanese. He was foremost among the economists who supported Joseph Chamberlain in his campaign for protection for British industry. His *Tariff Problem* (1903) was republished in a new and enlarged edition in 1920.

In addition to his professional and literary work, Ashley sat on many important public committees and commissions of inquiry. He also was joint author of the *Report* of the Unionist social reform committee on industrial unrest (1914). He died on July 23, 1927.

ASHTABULA, a city of Ashtabula county, O., U.S., on Lake Erie, 55 mi. NE of Cleveland. The city derives its name from the river flowing through it called *Hash-tah-buh-lah* (Algonkian, "river of many fish") by the Indians. (For comparative population figures *see* table in OHIO: *Population.*) The first permanent settler arrived in 1803. Matthew Hubbard came in 1804 and became a principal proprietor of the town; Hubbard house, built in 1834 by his brother Col. William Hubbard, was the last station on the underground railroad running from Kentucky to Lake Erie and is still in use standing on a high bluff overlooking the lake at Walnut beach. Because of its location on both the land and water routes from New England, Ashtabula became a stopping place for pioneers entering the Western Reserve. The village was incorporated in 1831 and received a city charter in 1891.

Because of the river, a deep gorge divides the city. One of the most tragic accidents in railroad history occurred on Dec. 29, 1876, when a train of 11 wooden coaches and 2 heavy engines laboured in a blinding snowstorm onto the bridge spanning the gorge. Suddenly the bridge collapsed, plunging 156 persons 75 ft. into the chasm, where the cars caught fire from the heating stoves and oil lamps and 85 people perished.

Industries include shipbuilding, the manufacture of automobile forgings, wood products, farm tools, leather processing, corrugated boxes, sheet metal boilers, plastic auto bodies and cabs, Fiberglas and greenhouse vegetable cultivation. The city is also an important chemical centre. In the 1950s oil drilling was resumed in the area. Two 2,000-ft. docks were added to the harbour facilities to accommodate St. Lawrence seaway shipping. (J. A. TA.)

ASHTON, FREDERICK (WILLIAM MALLANDAINE) (1906–), associate director of England's Royal Ballet and its principal choreographer, was born in Guyaquil, Ecuador, on Sept. 17, 1906. Ashton studied dancing in London under Léonide Massine, Nicholas Legat and Marie Rambert. Mme. Rambert encouraged his first choreographic efforts, in *The Tragedy of Fashion* (1926) and *Capriol Suite* (1930).

Ashton joined the Vic-Wells (later the Royal) Ballet in 1935 and distinguished himself as a mime and character dancer (*e.g.*, Carabosse in *The Sleeping Beauty*, the Gigolo in *Façade*), and as versatile choreographer of about 30 ballets including *Cinderella, Sylvia, Daphnis and Chloë* and the film *Tales of Hoffman* (1950). (LN. MR.)

ASHTON-UNDER-LYNE, a municipal and parliamentary borough of Lancashire, Eng., on the River Tame, a tributary of the Mersey, 6½ mi. E. of Manchester. Pop. (1961) 50,154; on April 1, 1954, part of the rural district of Limehurst was added to the borough and the population thereby increased to 51,335. The derivation from the Saxon *aesc* (ash) and *tun* (an enclosed place) accounts for the earliest orthography, Estun. The addition *subter lineam* is found in ancient deeds because the place is below the line or boundary of Cheshire, which once formed the frontier between Northumbria and Mercia. The manor was

granted to Roger de Poictou by William I, but before the end of his reign was transferred to the Greslets as part of the barony of Manchester. The mayor of the manor still holds the court leet half-yearly. There was a church or chapel there in 1261–62, but the church of St. Michael, begun in 1413, is almost entirely modern. Its stained glass windows are among the finest in England.

The ancient industry was woolen, but soon after the invention of the spinning frame the cotton trade was introduced and as early as 1769 the weaving of cotton yarn by machinery became the staple industry. In addition to cotton, important industries are gas and oil engines, air-conditioning plant, filter equipment, cigarette making, leather and leather goods, plastics and machine tools. There are large collieries in the neighbourhood.

Stamford park, presented by Lord Stamford, is shared with Stalybridge. Ashton-under-Lyne has two technical colleges (one opened in 1954) and a school of art. In 1847 a charter of incorporation was granted.

ASHUR (Assur), the ancient religious capital of Assyria (*q.v.*), identified with modern Qal'at Sharqat in northern Iraq, on a rocky headland overlooking the west bank of the Tigris river about 15 mi. above the mouth of the Little Zab. The first scientific excavations were conducted by a German expedition led by W. Andrae (1903–13).

The place was originally occupied about the middle of the 3rd millennium B.C. by a tribe that probably had reached the Tigris from Syria, for historical tradition refers to a succession of 17 kings dwelling in tents. In the early records Ashur was written as a Sumerian ideogram A-USAR, which may be interpreted as meaning that the place had quay walls. Ashur, or Ashshur as it was subsequently called, was a name applied to the city, to the country and to the principal god of the ancient people known as the Assyrians.

Strategically, Ashur was less well situated than Nimrud (Kalakh) and Nineveh, the other principal cities of Assyria, which were upstream on the opposite bank of the Tigris. But the religious sanctity of Ashur, associated with the memory of the earliest settlers, ensured its continuous upkeep until 614 B.C. when the city was destroyed by the Babylonians. At various periods its citizens enjoyed exemption from taxation. Between the 11th and 7th centuries B.C. several monarchs were buried within the city walls; a space was also reserved for the memorial stelae of the kings of Assyria from Adadnirari I to Ashurbanipal, including one of Queen Sammuramat (Semiramis).

Although it was the religious capital, Ashur was smaller than Nineveh, Kalakh and Dur-Sharrukin (modern Khorsabad). The inner city, which in the 9th century comprised about 150 ac., was defended by a circuit of walls nearly 2½ mi. long. On the eastern side it was washed by the Tigris, along the line of which massive stone and brick-built quays were first erected by Adadnirari I (reigned 1307–1275 or perhaps 1305–1273 B.C.). These were extended and repaired by subsequent kings. On the north side there was an arm of the river and a high escarpment reinforced by a system of buttressed defenses and by a powerful sally port named the *mushlalu*—a semicircular tower of rusticated stone masonry, built by Sennacherib, probably the earliest known architectural example of the kind. Tukulti-Ninurta I (reigned 1244–08 or perhaps 1243–06 B.C.) dug a ditch 20 m. wide along the western side, and 400 years later Shalmaneser III, who built the inner wall, shortened the line of defense and so made it easier to hold. Along this western wall there was a system of towers at intervals of 29–31 m. with a frontage of 8–10 m. projecting 4 m. from the wall. The towers were probably not less than 15 m. high and stood behind a curtain wall 11–12 m. high.

A text of Sennacherib mentions 13 gates as standing in the 7th century B.C., of which seven have been located. The earliest was the *gurgurri* gate in the northwestern corner. This is typically Assyrian in form, defended by heavy flanking towers with staircase leading from an inner guard chamber up to the battlements and closed by three double-leaved doors. Within the city there were paved streets sometimes reinforced with timber balks. A processional way led out of the *gurgurri* gate to a temple built by Sennacherib, the forecourt of which was planted with trees. A catalogue of the town buildings inscribed in the reign of this monarch shows that there were 34 temples in Ashur. Of these temples less than one-third have been found, including those of Ashur-Enlil, Anu-Adad, Sin-Shamash, Ishtar and Nabu; two of the three named are ziggurats, of which that of Anu-Adad, a mighty staged tower of burnt brick, is the best preserved.

Historically the most interesting temples are those devoted to the cult of the goddess Ishtar, or Inanna as she was known to the Sumerians. The associated objects show clearly that the first two foundations (*c.* 2600–2500 B.C.) bore the imprint of Sumerian culture. The fifth in the series belonged to a period when Ashur was ruled by an independent line of rulers, *c.* 1900–1800 B.C., and had trading colonies in Cappadocia. A break thereafter corresponds with a time when Ashur became subject first to Babylon, then to Mitanni, and was of no political importance. The cult however was revived by Tukulti-Ninurta I, who erected a temple to Ishtar-Dinitu ("of the dawn"). There is evidence to support the theory that at this time sexual intercourse took place within the temple under the aegis of the goddess, a practice later on ascribed by Herodotus to Babylon.

In addition to the temples, three palaces were identified. The oldest, ascribed to Shamshi-Adad I (fl. *c.* 1810 B.C.) was a building with a frontage of 112 by 98 m. and followed the plan of one that had been erected at Tell Brak in northern Syria five centuries earlier. Later this building was used as a burial ground. The many private houses found in the northwestern quarter of the site were often spaciously laid out and also had family vaults that were dug beneath their floors and contained many valuable votive deposits, including jewelry, weapons, metal bowls and pottery. The irregular planning of the town and its tortuous streets indicate a strict respect for property rights and land tenure. Other aspects of Assyrian law, particularly relating to women, are known from a series of tablets compiled in the period 1450–1250 B.C. Many inscriptions found include historical and especially religious texts, as well as business documents. Stone sculpture, both in the round and in relief, illuminates the history of Assyrian art at many different periods, as do the thousands of small objects found in the ruins.

Evidence of the sack of Ashur is seen in the violent burning of the *gurgurri* gate, the breaching of the walls and the presence of sappers' tools and arrowheads. When in 401 B.C. the army of 10,000 Greeks commanded by Xenophon passed by, even its ancient name had been forgotten. Even so, some pottery types appear to indicate traces of occupation in the Seleucid period. A part of the city was revived either shortly before or shortly after the Parthian conquest of Mesopotamia (140 B.C.) when a temple was dedicated to Ashur and Sherua, and a vast palace with peristyled courts and pillared hall was erected. *See* Babylonia and Assyria.

ASHURBANIPAL (Assyrian Ashur-bani-apli) (reigned 669–630 or 626 B.C.), the last of the great kings of Assyria, had been proclaimed crown prince of Assyria during his father Esarhaddon's reign, his brother Shamash-shum-ukin being simultaneously nominated crown prince of Babylonia. His first military concern at his succession was the settlement of Egypt, which Esarhaddon had conquered shortly before his death. The former Egyptian king Tarku (biblical Tirhakah), who had invaded the delta from the south, withdrew at the approach of the Assyrian army, and Ashurbanipal set up an administration under native princes, backed and controlled by Assyrian garrisons. Intrigues between the delta princes and Tarku were discovered and the ringleaders arrested and sent to Assyria. Here Ashurbanipal showed his statesmanship and, forgoing revenge, appointed Necho, one of the princes concerned, as paramount ruler over the delta under Assyrian tutelage. An invasion by Tarku's successor provoked a further Assyrian campaign in Egypt (663 B.C.), during which the Assyrian army destroyed Thebes—an event recalled in

Nahum iii, 8. In the same year Necho died and was succeeded by his son Psamtik.

The pacification of Egypt allowed Ashurbanipal to deal with the Phoenician city of Tyre, which, after siding with Egypt during Esarhaddon's reign, had since withstood a long siege. The kings of Syria and Cilicia hastened to make submission, while Gyges of Lydia, farther west, sought assistance against invading Cimmerian hordes. The Lydian alliance was short-lived, for soon afterward Lydia supplied troops to Psamtik, who had become supreme in the delta and now asserted his independence, expelling the remaining Assyrian garrisons from Egypt by 654 B.C.

The former good relations between Assyria and Elam were ruptured by an attempted Elamite invasion of Assyrian territory during the Egyptian campaign. Once Egypt no longer engaged the Assyrian army, Ashurbanipal, after a brief campaign in the northeast, turned his attention to Elam, conquering the land and setting up a pro-Assyrian king.

In Babylonia Shamash-shum-ukin, loyal to his brother for more than 15 years, now organized a hostile coalition and in 652 B.C. rebelled. His principal ally, Elam, was paralyzed by dynastic troubles, and the Assyrian army was able in 648 B.C. to starve out the Babylonian cities, despite attempts by Arab allies to break the siege. Shamash-shum-ukin himself committed suicide, and Babylonia was placed under a puppet ruler Kandalanu.

With Babylonia settled, Ashurbanipal attempted to re-establish order from the chaos into which Elam had fallen. After several unsuccessful efforts at setting up friendly Elamite princes, Ashurbanipal lost patience and undertook a major punitive campaign in which the principal cities and shrines suffered severely.

Little is known of the events of the final years of Ashurbanipal's reign, but it is clear that the decline of Assyria had set in: the immediate cause was probably economic, the intrusion of Cimmerians and Scythians to the north and of Indo-Aryan peoples to the east having dislocated vital trade routes.

Ashurbanipal's most lasting achievement was in the realm of culture. Some would discount his boast of special ability in the scribal arts, but he certainly showed great interest in literature in collecting at Nineveh a great library of cuneiform texts. This library, discovered in the early days of Assyriology, still forms the basis of that science and is of unique value for the light which it sheds on ancient life and thought. *See* BABYLONIA AND ASSYRIA; *see* also references under "Ashurbanipal" in the Index.

ASHURNASIRPAL (Assyrian ASSUR-NASIR-APLI, "the god Ashur is guardian of the son"), the name of two Assyrian kings.

ASHURNASIRPAL I, son of Shamshi-Adad IV and uncle of Tiglath-pileser I, ruled Assyria *c.* 1049–31 B.C. His few surviving inscriptions show that the country was impoverished by frequent intruders from the western deserts against whom he warred constantly. Ashurnasirpal I lived in a large palace southwest of the ziggurat at Ashur and used Nineveh as an alternative capital, if a sculptured obelisk found there (now in the British museum) is to be attributed to him rather than to Ashurnasirpal II.

ASHURNASIRPAL II was king of Assyria from 884 to 859 B.C. His great achievement was the consolidation of the conquests begun by his father, Tukulti-Ninurta II, leading to the establishment of the New Assyrian empire. In seven years of arduous campaigning he first subdued the Aramaeans in the upper Euphrates valley and imposed taxes on the states of Laqe and Hindanu. He also marched unopposed to the Mediterranean sea and received tribute from the cities of Phoenicia.

In the north he thwarted Aramaean pressure on the Assyrian city of Damdamusa by storming the rebel stronghold of Kinabu and ravaging the land of Nairi (Armenia). He organized a new Assyrian province of Tushhan to control the border, and there he received tribute from his father's former opponent Amme-ba'ali. In 879 B.C., however, the tribes in the Kashiari hills revolted against Tushhan and murdered Amme-ba'ali. The Assyrian revenge was swift and ruthless.

One reason for the growth of Assyrian prestige and wealth during this reign was Ashurnasirpal's ability to maintain authority over the peoples in the hills to the east. Early in his reign he publicly flayed the rebel governor of Nishtun at Erbil (Irbil) and, in a brief expedition in 880 B.C., dislodged the rebels holding the Babite pass which controlled a main caravan route. Zamua was then made an Assyrian province with a new capital at Atlila.

Ashurnasirpal used the many captives from his campaigns to build a new capital at Kalah (the modern Nimrud). By 879 B.C. the main ("northwest") palace in the citadel, the temple of Ninurta and Enlil, shrines for nine other deities and the city walls had been completed. Botanical gardens and a zoological garden were laid out, and water supplies were assured by a canal from the Great Zab river. The inscriptions and reliefs from this city, to which the king moved from Nineveh, are the principal source for his reign. One of these described his campaigns, building activities and the feast given for ten days to 69,574 people to celebrate the opening of Kalah. A statue of the king (now in the British museum) was found by Sir A. H. Layard in the Ninurta temple in 1847.

See BABYLONIA AND ASSYRIA; NIMRUD.

ASH WEDNESDAY in the Western Church is the first day of Lent, the fast of 40 days (in imitation of Jesus Christ's 40-day fast in the desert) in preparation for Easter. In the 8th century, Lent in the west began six weeks before Easter and thus 40 days before Good Friday, but as there was no fasting on Sundays it included only 34 days of fast. In order to make up the number of fasting days to 40, four days were added before the first Sunday, and Good Friday and Holy Saturday were counted in also. Lent therefore began six and a half weeks before Easter, on the Wednesday preceding the first Sunday in Lent.

At about the same period in Rome the rites of public penance for notorious sinners coincided with the beginning of Lent. The ceremony of admitting penitents occurred on this Wednesday; they were sprinkled with ashes, dressed in sackcloth and obliged to remain apart until the end of the period of public penance and their reconciliation with the Christian community on Maundy Thursday. When these rites fell into disuse (8th-10th centuries), the beginning of the penitential season of Lent was symbolized by the imposition of ashes on the heads of the whole congregation, clergy and people. Nowadays the ceremony takes place with the marking of a cross on the forehead with the ashes obtained by burning the palms used on the previous Palm Sunday.

In the Anglican Book of Common Prayer a commination service replaces the earlier penitential discipline on this day. Ash Wednesday is also observed in Lutheran churches. Orthodox churches begin Lent on a Monday and therefore do not keep Ash Wednesday. *See* also LENT; CHURCH YEAR.

See H. Thurston, *Lent and Holy Week* (1904); N. M. Denis-Boulet, *The Christian Calendar* (1960). (L. C. S.)

ASHWELL, LENA (originally LENA POCOCK) (1872–1957) British actress, who during World War I organized entertainment for the troops at the front, was born on board ship in the Tyne, on Sept. 28, 1872. She acted with Sir Henry Irving in 1895 in *King Arthur,* and again in 1903 in *Dante,* but established her reputation in Henry Arthur Jones's *Mrs. Dane's Defence* with Sir Charles Wyndham in 1900. Other successes were *The Darling of the Gods* (1903) and *Leah Kleschna* (1905).

From 1907 to 1915 she managed the Kingsway theatre. Later she formed the Lena Ashwell Players and for several years produced good drama at low prices at the Century theatre. In 1908 she divorced the actor Arthur Playfair, whom she had married in 1896, and married Henry (later Sir Henry) Simson. In 1916 she received the Order of the British Empire for her services during the war. She died in London on March 13, 1957. (W. J. M.-P.)

ASIA, the largest of the continents with an area of 17,139,445 sq.mi., has as its conventional western boundaries the Ural mountains and Ural river to the Caspian sea, the Caucasus to the Black

sea, the Mediterranean coasts of Asia Minor and the Levant, and the Red sea. In the east, the Indonesian archipelago and the island chains stretching north through Japan to the Kamchatka peninsula are considered Asian. Viewed on the globe, Asia is a great isosceles spherical triangle having two sides of 6,500 mi. extending from Bering strait to Aden and Singapore respectively, the third side measuring 4,500 mi. and enclosing the Arabian sea and the Bay of Bengal.

This article is organized according to the following outline:

I. PHYSICAL GEOGRAPHY

A. Geologic History

Continents are thought to be formed by the addition to relatively stable nuclear areas, or shields, of fold mountain systems formed from sediments accumulated in geosynclinal troughs. Four major mountain-building episodes may be recognized in Asia, during which portions of previous systems and of the ancient nuclei themselves have been incorporated into the new system along with the younger sediments (*see* fig. 1). Two main groups of Pre-Cambrian shields are distinguishable. The northern, comprising Angaraland and the lesser nuclei (largely submerged) of the Kara and Chukchi seas, appears to have played a more active part, while the southern Gondwanaland group, including Arabia and the Indian peninsula, remained relatively unaffected by movements. The extent of these land masses in Pre-Cambrian times was probably very much greater than that of their present known area, outcropping or concealed beneath later formations. Angaraland together with the Cathaysian land mass, fragments of which formed nuclei in south China and around the Gulf of Chihli, are regarded by some authorities as part of a vast northern continent, Laurasia, stretching through Asia to Europe and North America. A geosynclinal trough, the Tethys sea, separated Angaraland from Gondwanaland.

Little is known of Pre-Cambrian movement in Asia, though one such mountain-building period occurred in south India. The first orogeny for which widespread clear evidence is known, the Caledonian, lasted from Cambrian to Devonian times. The Sayan and Altai mountains show Caledonian structures also found partly obscured by later folds in the Verkhoyansk range. Movement probably took place over a wide area in Outer Mongolia and even in the Himalayas and Indochina. Around the Kara sea nucleus the trends run through Severnaya Zemlya, and west of the Chukchi nucleus through the New Siberian Islands (Novosibirskie Ostrova).

The Variscan or Altaid orogeny spans Carboniferous to Triassic time and has a more extensive influence than did the Caledonian, a good deal of which was probably reabsorbed by the new movements. Fresh folding took place around the Kara sea nucleus, particularly on the west in Novaya Zemlya, whose structures continue in the Urals on the mainland. Hidden Variscan folds may underlie later deposits in the west Siberian plain, and represent extensions of the structures outcropping in the Kazakh uplands. These in turn are linked to fold systems encompassing the southwestern corner of Angaraland; *e.g.*, the Altai, Tarbagatai mountains and Dzungarian Ala-Tau. Much of central Asia was molded at this time, when local nuclei of Fergana and Tarim in the west and Ordos in the east formed stable regions, later to founder as basins, around which fold mountain chains were thrown up. The east-west Astin Tagh (Altyn Tagh), Nan Ling and Tsinling ranges follow the Variscan trend, which may also be seen in parts of the Himalayas, in the Shan states of Burma, Thailand, Malaya and west Borneo. Possibly Formosa, Japan and Korea have Variscan folds, around the east of the south and east China nuclei.

In the far east generally, however, the Yen Shanian (Jurassic-Cretaceous) orogenic epoch was more important. Block faulting, vulcanicity and granitization were more significant than folding in the central parts of this region. Thick Triassic-Jurassic deposits between Angaraland and the Chukchi nucleus were folded up in the Verkhoyansk and Cherski ranges. The Sikhote-Alin (U.S.S.R.), South Korea and south Honshu were all affected, while between the east China and Ordos nuclei occurred the folds of the Shensi coal field. The Nan Ling and other east-west trends of the south China coast are of the same epoch, and continue through the northern Indochina peninsula, Thailand and Malaya into southwest Borneo.

The products of the final phase of mountain building stretch in an immense chain flanking on the south and east all earlier systems and abutting onto the massifs of Arabia and India. Starting in Turkey the ranges run eastward converging on the Armenian knot where they open out southeastward. The Caucasus, continued across the Caspian as the Kopet Dagh, join the system in northeast Iran. In Afghanistan and Baluchistan the influence of the Indian shield is seen in the northward sweep of the Kirthar and Sulaiman ranges and the narrowing of the fold belt in the Pamir knot. In northeast India the trend turns sharply south in the hills of north Burma and continues through the Andaman and Nicobar islands to Sumatra, into the tortuous arcs of Indonesia. Continuing northward in Formosa and Japan, the mainland is reached again in Kamchatka. Severe earthquakes have occurred in the 20th century throughout the Alpine-Himalayan belt in Asia. The greatest instability, evidenced by active vulcanicity and frequent earth tremors, is associated with the island arcs of Indonesia and the far east, where it is possible the orogenic epoch has not yet reached its climax.

B. Geology and Relief

Asia presents a great variety of relief forms generally of an incomparable scale. The open ancient landscapes of the plateaus of Arabia and India merge almost imperceptibly with the youthful alluvial plains of the Tigris-Euphrates and the Indus and Ganges where the deltas of mighty rivers continually extend the land area. Above the plains rise abruptly the flanks of the youngest and most vast mountain system, which borders in its turn the high plateaus, block mountains and basins of the "roof of the world." Northward, high Asia gives way to the broad sweep of lowlands and low plateaus which extend from east Siberia to the Atlantic. To the east great spurs, between which the diligent rivers have built up the flat alluvial plains now teeming with humanity, reach toward the Pacific.

For more detailed treatment of geology and relief, Asia may conveniently be divided into eight regions: (1) the Arabian massif and plains of Iraq; (2) peninsular India and the Indo-Gangetic plain; (3) the mountain belts of Turkey, Caucasia, Iran, Afghanistan; (4) the Himalayan system from Baluchistan to Burma; (5) central Asia; (6) the lowlands of Asiatic U.S.S.R.; (7) the Pacific borderlands; (8) the island arcs.

Arabian Massif and Plains of Iraq.—Pre-Cambrian rocks are extensively exposed along the Red sea and in central Arabia. From Cambrian times onward marine strata have been laid down, Mesozoic and Tertiary being well represented. These formations, generally little disturbed, are arched and faulted west of the Jordan and slight rucking of the strata is found as the Alpine fold belt of Turkey, Iran and Oman is approached. There occur the important oil fields of the middle east. The dominant structural feature of the region is, however, the rift valley system of Tertiary age, to which the Red sea, Dead sea and Jordan valley belong. Vulcanicity accompanied the strong fault movements, producing the prominent lava flows that form the high ground in Yemen (up to 12,336 ft.), northern Hejaz (9,400 ft.) and southern Syria (5,938 ft.).

From its high western rim the Arabian plateau slopes gently to the plains of Iraq and the undulating coastlands of the Persian gulf. Seasonal watercourses abound and many features indicate

FIG. 1.—STRUCTURAL HISTORY OF ASIA

more humid climates of the past. Only the Tigris, Euphrates and a few Mediterranean rivers are perennial.

Peninsular India and the Indo-Gangetic Plain.—Stability has characterized the geologic history of the peninsula since early Cambrian times, though faulting, large-scale movements of the earth's crust and the outpouring of the Deccan lavas complicate its surface evolution. Over a great area the gently undulating landscape is composed of very ancient granites and gneisses above which rise abruptly occasional isolated granite hills. The larger masses of highland in the south, *e.g.*, the Nilgiri hills (8,640 ft.), and in Ceylon appear to be due to post-Jurassic upthrust.

A unique feature of India's structural evolution was the sinking of fault-bounded troughs and the accumulation therein of fresh-water deposits over a period lasting from about the close of the Carboniferous to the early Cretaceous. The most important area of these Gondwana rocks, in which thick coal seams occur, lies along the Damodar valley. Apart from evidence of marine Permo-Carboniferous limestone near Jabalpur, only the fringes of the peninsula experienced marine incursions, in Mesozoic and Tertiary time. In the northwest of the peninsula the eruption of the Deccan lavas in the late Cretaceous or early Eocene covered 200,000 sq.mi. with flat basalt flows.

The Western Ghats form the plateau edge to the west and stand 4,000 to 5,000 ft. above the Arabian sea. Eastward the plateau slopes gently to broad plains in Madras. A number of rugged hill groups toward the east reach 3,000 ft. but plains and broad valleys dominate the landscape. In the northeast the more extensive Chota Nagpur plateau reaches from 2,000 to 3,500 ft. and the Shillong plateau beyond the Ganges delta represents an outlier of the peninsula block. Across the north centre of the peninsula, the Tapti and Narbada rivers and the Satpura and Vindhya ranges form an important dividing zone, north of which the southwest-northeast-trending Aravalli hills gradually become submerged beneath the recent deposits of the plains.

The Indo-Gangetic plains are remarkable for their level surface broken only by steep river bluffs. Delhi, 1,000 mi. northwest from the Ganges' mouth, is 718 ft. above sea level. Toward the Himalayan foothills clays and silts give way to coarse gravels—the "bhabar" country.

Turkey, Iran and Afghanistan.—These countries with west Baluchistan are made up of numerous fold and block mountains enclosing broad basins, often with interior drainage. The Elburz (Mt. Demavend, 18,580 ft.) and Koppeh Dagh in north Iran run east in the Hindu Kush of northeast Afghanistan, while to the south lies the broader Zagros system with several peaks over 14,000 ft. and having a northwest-southeast trend through south Iran, branching into Oman and sweeping north in Baluchistan. The principal oil fields of the middle east are associated with the Zagros and its "ripple folds" against the Arabian massif. The two mountain systems enclose several saline basins, *e.g.*, Seistan, Lut, where also recent volcanic cones occur.

The simplest elements of the more complicated structure of Turkey are the Pliocene volcano, Mt. Ararat (16,945 ft.), from which the Anti-Taurus and Taurus run toward and along the Mediterranean coast, and the Pontic mountains along the Black sea. The fringing ranges enclose several basins on the Anatolian plateau, some containing bitter lakes; *e.g.*, Lake Tuz and Lake Van. Around Zonguldak on the Black sea lies an important Carboniferous coal field and elsewhere there are extensive chrome and manganese deposits. Modern earthquakes indicate the continuing instability of the region.

The Himalayas.—The influence of partly hidden extensions of the massif of southern India on the changes in direction of the fold systems of Tertiary age has been referred to above. The main 1,500-mi. chain of the Himalayas has generally five longitudinal divisions. Separating the system from the Tibetan plateau are the valleys of the upper Indus and Brahmaputra (Tsangpo), from which rise to the south the Great Himalaya with about 60 peaks over 24,000 ft., culminating in Everest (29,028 ft.). Nanga Parbat (26,660 ft.) and Namcha Barwa (25,446 ft.) mark the extremities of the range, south of which spreads a deeply dissected apron of spurs with summit levels of about 15,000 ft. The Lesser Himalaya comprise a number of ranges, sometimes over 12,000 ft. and enclose some basins, the largest being the vale of Kashmir. An abrupt descent follows to the Siwalik hills, with a maximum height of 6,345 ft., formed of coarse detritus brought down from the rising Himalayas in mid-Pleistocene times.

Central Asia.—The Tibetan plateau averages about 16,000 ft., rising in the Karakoram on the southern edge to 28,250 ft. in K2 (Godwin Austen). Heights of over 20,000 ft. are reached in the Pamirs and the west-east-trending Tien-shan, while several basins sink to about 9,000 ft.; *e.g.*, Tsaidam swamp in the Tsinghai province of China. The unique Turfan oasis lies 505 ft. below sea level. The range of altitude is more significant than absolute height above sea level. Many of the basins are enclosed drainage systems and those to the northeast, *e.g.*, the Gobi desert, have suffered much wind erosion.

Lowlands of Asiatic U.S.S.R.—This term is strictly relative

as the region includes the low central Siberian plateau, below 1,000 ft., between the Lena and Yenisei valleys. West of the Yenisei the unfolded Mesozoic and Tertiary deposits of the west Siberian plain stretch to the Urals which are conventionally regarded as in Europe. The surface is often marshy as in the Vasyugane swamps. To the southeast the Kuznetsk and Minusinsk basins, containing Paleozoic coal, form foothills to the Altai and Sayan ranges. The Kazakh uplands, averaging 1,000 ft., form the southern limit of the plain. There are a number of inland drainage basins, the climate being increasingly arid toward the Kirgiz steppe to the south, which includes the open plains of Turan east of the Caspian. The Syr- and Amu Darya rivers provide strips of irrigated cultivation. There are considerable tracts of sand, clay and alkali desert; *e.g.*, Kyzyl-Kum and Kara-Kum. Oil fields are exploited around the shores north of the Caspian.

Pacific Borderlands.—These include a variety of regions stretching from east Siberia through China to Malaya. East of the Lena, the Verkhoyansk and Cherski ranges rise to 8,200 ft. Kamchatka, with active volcanoes rising to over 15,000 ft., consists of two north-south ranges enclosing a basin. The relief of the Bureya highlands and Sikhote-Alin on either side of the Amur river is below 8,000 ft.

China is characterized by rejuvenated relief of fault blocks of Yen-Shanian orogeny and very young alluvial plains. Manchuria is a plain of erosion flanked by tilted blocks: the Greater Khingan, Jehol and Liaotung, the latter being cut off by the sea from the similar Shantung peninsula block. Korea is compounded of dissected plateaus and zones of mainly Mesozoic folding. The southeast China block is much faulted as is also the broad folded zone to its west. The P'o-yang and Tung-t'ing lake basins and the Hsi Chiang (or Si Kiang) valley occupy structural depressions in clays and slates. Westward two broad steps deeply dissected by valleys lead into the 6,000-ft. plateau of west Yünnan. Its spurs enclose the Red basin of Szechwan, to the north of which the Tsinling Shan, with rugged ranges up to 13,474 ft., forms a major divide across China.

The Ordos plateau, rigid since Permian times and covered with great thicknesses of undisturbed loess and older terrestrial deposits, forms the nucleus of northwest China. Loess redistributed by rivers clogs the valleys and has been carried down the Yellow river (Huang Ho) to form the north China plain. Both Yellow river and Yangtze plains are very young; lakes and alternative channels abound, and disastrous floods have been common.

The Yünnan plateau continues south of China into the Shan plateau of Burma and Indochina, deeply cut by the Salween and Mekong rivers. The highlands branch southward to enclose the deltas of the Chao Phraya or Mae Nam and Mekong. Rarely do heights exceed 10,000 ft. and in hilly Malaya the highest point is 7,186 ft.

The Island Arcs.—From Sumatra to Japan lies a belt of great instability. In Indonesia the evidence of volcanic chains, double island festoons and anomalous gravity values has been taken to indicate that orogeny is there in its infancy. A Mesozoic block including Malaya and west Borneo has probably been a buffer to Tertiary folding, and the Tertiary deposits include petroleum. The highest peaks are usually volcanic cones of which Java has several over 10,000 ft. In Japan faulting rather than folding is combined with vulcanicity. An outer, eastern rugged mountain zone on older folded strata cut by faults is distinguished from an inner western zone of younger block faulting and active vulcanicity. A deep rift in which rises the cone of Fujiyama (12,388 ft.) cuts across central Honshu. Plains of young alluvium, flanked by older gravels, occupy a relatively small area in this land of steep slopes.

C. Climate

The classic theory of the monsoons as explaining the climate of much of Asia has undergone radical revision in the light of the more intensive meteorological research into the dynamics of the upper atmosphere that took place during and after World War II. Among the most important factors influencing the climate of a place is its position in relation to the general planetary circulation of the atmosphere, upon which the distribution of high mountains and of land and sea masses has an effect. Local factors also have their effect, such as distance from and altitude above the sea and the configuration of the land surface.

As far as Asia is concerned, the planetary circulation consists of three elements:

1. The circumpolar vortex of the westerlies extending into the upper layers of the atmosphere, within which lies the jet stream, generally at a height of over 30,000 ft. and sometimes several hundred miles wide. Within the jet stream the velocity of air flow is much above that of the main body of the westerlies. According to G. T. Trewartha, the jet stream has an important regenerative and guiding effect on the depressions which follow beneath it. In summer the jet stream lies over the U.S.S.R. north of the mountains of central Asia and cyclonic disturbances tend to follow tracks west to east across central Siberia bringing rain to the steppes. In winter, with the southerly shift of the circumpolar vortex, the jet stream is caused to split in two by the highlands of central Asia, one branch passing south of the Himalayas and a weaker branch fluctuating in position north of the highlands. Over central China the branches converge to flow northeastward across Japan.

2. Equatorward of the westerlies there lies at the surface a belt of easterlies: the trade winds. These are strongest over the west Pacific ocean at all seasons, but are operative only in winter over the Indian ocean.

3. Air rising over the easterlies joins the general westerly whirl of the atmosphere at high altitudes. At the surface there is also a countercurrent, however—a belt of equatorial westerlies, normally quite narrow over the sea. It has been suggested by H. Flohn that this stream of air widens in summer to produce the so-called southwest monsoon over India and southeast Asia and presses eastward to meet the west Pacific trade-wind flow over China.

The climate of Asia can in large measure be described in terms of these three wind systems and the cyclonic disturbances that they generate through bringing into contact air masses of contrasting character, through dynamic causes due to air flow over the irregular surface of the land and through thermal causes due to the differential heating of the surface. The details of the climate may best be treated under the following regional divisions: Asiatic U.S.S.R., southwest Asia, India-Pakistan, southeast Asia and the far east.

Asiatic U.S.S.R.—With the exception of Transcaucasia, the Soviet Union's "greenhouse" sheltering south of the Caucasus, the whole of the U.S.S.R. lies exposed to influences from north and west. The lack of mountain barriers in this vast area stamps its climate with certain common traits: cold winters, warm to hot summers and low rainfall.

Siberian winters are notoriously cold and the lowest temperatures recorded in the northern hemisphere are almost invariably to be found there. The Siberian high-pressure system engenders calm, sunny weather as a rule and rarely can depressions break through bringing dreaded blizzards. Only the southern Caspian and Black sea coasts have January means above freezing. Summer follows winter with amazing rapidity. The Arctic ocean and large lakes tend to reduce temperatures locally, but south of the Arctic circle July means are over 60° F. and Verkhoyansk's record is 93°. In the central Asia republics July means of over 80° F. are found.

Only Transcaucasia, the middle Amur basin and Kamchatka have more than 20 in. of precipitation. Large areas in the central Asia republics and toward the Arctic circle receive less than 10 in., leaving a belt tapering eastward from the Urals with 10–20 in. Rainfall is generally concentrated in the summer months when frequent shallow depressions pass eastward across the steppes. Transcaucasia has rain at all seasons, while the fringe of the central Asian highlands receives most rain in winter. In the far eastern region a slight monsoonal effect brings late summer rain and polar frontal depressions pass parallel to the coast. In neither case, however, does precipitation extend far inland. There and on the Arctic coasts summer fog is prevalent.

Southwest Asia.—Despite the penetration of the Red sea and the Persian gulf, aridity is the keynote of this area, which lies between the Mediterranean and West Pakistan and south of the U.S.S.R. Most of what little rainfall the region receives is brought by westerly depressions moving in winter under the jet stream from the Mediterranean toward India. The summer is dry except in the areas bordering the Black sea, which enjoy convectional storms, and in the southern tip of the Arabian peninsula, which is high enough to extract some moisture from the monsoon air stream flowing toward India.

Temperature contrasts are very great. In winter the plateaus become extremely cold and there is widespread snow. Kabul has a January mean of 31° F., Tehran 34° and Ankara 28°, and the mean minima indicate even better the severity of winter: Tehran 26°, Ankara 17°, Mosul 32°. Everywhere, except perhaps on the southern Arabian coasts, temperatures may vary rapidly from day to day with the passage of depressions, in the advance of which warm air is drawn northward from the southern deserts, raising temperatures as much as 40°, to be followed by an equally sudden fall brought by cold northwesterly blasts in the rear. Only the coastlands of the Mediterranean (Beirut, January mean minimum 50° F.), the Persian gulf, Makran and, above all, the southern fringes of Arabia (Aden, January mean minimum 73° F.) can claim really mild winters.

Summer is everywhere very hot, tempered in the north by altitude (though by day enclosed mountain basins may be ovenlike) and elsewhere by winds, which though often dust laden help to make high temperatures bearable. Almost the whole of the region apart from Turkey and western Iran has daily maxima exceeding 100° F. in July. The slightly lower temperatures of coastal areas, *e.g.*, the Persian gulf and Aden, are much more uncomfortable because of the higher relative humidity.

India-Pakistan.—The seasonal rhythm of climate in the subcontinent is apparently linked to the alternating dominance of the winter jet stream and the equatorial westerlies. The northeast trade winds are a minor factor in winter. Depressions, some probably of Mediterranean origin, traveling along and developing in the zone of convergence beneath the jet stream, bring vital winter rainfall to northwestern districts. South of the jet stream subsiding air from aloft maintains winter drought over central India. The removal of the jet stream to north of the Himalayas in summer seems an essential precondition to the sudden inflow of moist equatorial air from the southwest, which brings heavy rainfall to the Western Ghats (Mahabaleshwar 261 in.), Bengal and Assam (Cherrapunji 428 in.) and the eastern Himalayas (Darjeeling 123 in.). Precipitation diminishes in the rain shadow of the Ghats (Bijapur 20 in.) and up the Ganges valley, becoming negligible in the Thar desert and farther west (Jacobabad 4 in.). In the northeast the main period of the rains is preceded by increasingly frequent storms from March onward. It is a popular misconception that the monsoon rains fall continuously for weeks. Rather they come with marked periodicity, rainless episodes of increasing length occurring as the season progresses and the distance from the sea increases. A notable feature of the rainfall is its variability from year to year, this being most pronounced in areas of low average precipitation.

With the reappearance of the jet stream south of the Himalayas in the autumn, rain-bearing air masses can no longer penetrate from the south and the dry season begins. Southeastern India, however, and northern Ceylon experience their season of maximum rainfall from October to December as the equatorial air masses retreat south, giving way to northeast trades over the Bay of Bengal. Tropical cyclones add to the autumn precipitation.

Temperature conditions emphasize the vast extent of the subcontinent and one can refer to a "continental" northwest and a "tropical" peninsular India. In the plains of the Punjab several slight frosts may be experienced each cold season, though day temperatures may rise into the 70s. The hot season brings excessively high temperatures to the same region, with mean June maxima over 110° F. in places. The arrival of the rains brings welcome relief by day, though night temperatures may remain in the 80s. The annual and daily range of temperature is much less in the lower Ganges valley and the peninsula. In the far south Trivandrum has a yearly range of 5° F. compared with 20° at Calcutta and 40° at Lahore, and a daily range of only 12° in January, *cf.* Lahore 29°.

Southeast Asia.—This area includes the broad peninsula lying between India and China, tapering southward into Malaya and the Indonesian archipelago. Except in the interior of the mainland, maritime and equatorial influences are all-important. Temperatures at sea level maintain a daily mean of about 80° F. in the archipelago. The annual range increases northward: Singapore 3°, Rangoon 10°, Mandalay 20°. Air flow across the equator alternates seasonally and rainfall regimes depend largely on aspect. Thus the coastal uplands of Vietnam lie across the path of the west Pacific trades in winter and with the northern flanks of the islands receive rain at this period. The equatorial westerlies of summer impinge most strongly on Burma, Thailand, South Vietnam and the south coasts of the islands. The Philippines and Vietnam also have much rain from late summer typhoons. Between the seasons of fairly constant air flow, Malaya and Indonesia are in the doldrums and calm thundery weather predominates.

Much of the archipelago and Malaya have rain at all seasons but on either side of the equator occur dry seasons characteristic of monsoon climates. From east Java to Timor the islands have a dry season during the southern winter. Northern Malaya has one month dry and the period lengthens northward: Akyab (Burma) has four months with under 2 in. in a total of 203 in. The dry season is accentuated in the "dry belts" of Korat (Thailand) and central Burma, where Mandalay, total 33 in., has only 0.8 in. between December and March.

The Far East.—China north of the Tsinling Shan has a severely continental climate, characterized by extremes of temperature and low rainfall. Central and south China and Japan by contrast have a humid temperate to subtropical climate. In winter the difference between these two major divisions is greatest; *e.g.*, January mean temperatures: Mukden 9° F., Peking 23°, Tokyo 37°, Hong Kong 60°. The southern branch of the jet stream in the westerlies is joined by the weaker northern branch over central China, and depressions intensify there and during their passage northwestward across the China sea and the Japanese islands. Some develop dynamically as passing lee depressions in air sweep across the Tsinling Shan from the high-pressure centre of northeastern Asia. The depressions draw moist air into central China and bring rain, while the north remains dry because of its outflowing air streams. Japan's winter rain and snow are heaviest on the west which is exposed to cold blasts from the mainland.

In summer China becomes the meeting ground of the equatorial westerlies and the trade winds. As in India, the removal northward of the southern branch of the jet stream is the signal for the beginning of the early summer *baiu* rains. Precipitation, heavy over south and central China (from 40 in. to more than 60 in. annually), decreases northward to less than 10 in. in the bend of the Yellow river. The coasts of southern China and southern Japan may suffer destructive typhoons from June to November. Because of its maritime position Japan has over 60 in. of rainfall except in the north. Unlike winter, summer temperatures are remarkably similar throughout the far east; *e.g.*, July means: Mukden 76° F., Peking 78°, Tokyo 78°, Hong Kong 82°.

D. VEGETATION

Two major factors which determine the vegetation of much of Asia are the monsoon winds and the lofty mountains which intercept them. The seasonal alternation of the monsoons in the south and east causes an alternation of wet and dry seasons. In these regions there has developed a vegetation composed of plants which can reduce their activities during the dry season. This condition

parallels that in the north, where there is an alternation of warm or temperate and cold seasons. The central and southwestern portions of Asia for the most part can support only desert or steppe communities, because the surrounding mountains and the great distances from the seas prevent moisture-laden winds from reaching these areas. These general conditions are greatly altered in various parts of the continent because of local conditions and so give rise to a great diversity in the vegetation of Asia.

The flora of northern Asia is essentially similar to that of northern Europe and is composed largely of the same genera. Indeed, many species are circumpolar in their distribution. Some Mediterranean genera extend eastward across northern Asia Minor and on to the Himalayas, and a few elements reach as far as China. The deserts of interior Asia are continuations of the desert areas of Africa and Arabia with much the same types of plants; many of the genera are found throughout.

The vegetation changes somewhat toward central Asia in accordance with the change of climate from the hot and dry conditions of the southwest to the alternate extremes of hot summers with cold nights and cold winters at the high altitudes and latitudes of Tibet, Chinese Turkistan and Mongolia. These deserts lack such distinctive plants as the succulent cacti of the new world and the peculiar euphorbias which are characteristic of the drier parts of Africa.

Temperate and subtropical eastern Asia has the richest flora of any similarly located region of the world. Although the region is controlled by the alternating monsoons, great floral diversity results from variations in the configuration of the land and its range from the uniformly hot climate of the tropical zone northward into latitudes where severe winters prevail. This flora has many elements in common with the Himalayan and Indo-Malayan floras and shows striking relationships with the flora of eastern North America. There are also many genera and even families which are unique to this area.

FIG. 2.—MAJOR VEGETATION REGIONS OF ASIA

Southern and southwestern Asia has a rich tropical flora reflecting the generally abundant summer rains and mild to hot climate. The vegetation of India is composed of somewhat different floral elements from that in Indochina, the Malay peninsula and the Malay archipelago. They are differentiated as the Indian and the Indo-Malayan floras respectively. Especially in the southeastern part of the Malay archipelago there are many representatives of the distinctive Australian flora.

Northern Asia.—The combination of low humidity and severe winters along the arctic margin of the continent results in a scanty low vegetation known as tundra. The vegetation of the plateau region beginning east of the Yenisei river and reaching to the Stanovoi mountains forms the great tundras of Siberia, composed of low, flowering plants, such as sedges, dwarf birches and willows, with numerous mosses and lichens. The area is better drained and the winters are even more severe than they are toward the west. Forests of small trees occur in the lower and more sheltered parts with the tundra stretching southward on the ridges. Farther south occur distinctive forests or taigas, often swampy, which extend to the coniferous forests and meadows of the Siberian highlands in the general vicinity of Lake Baikal.

South of the swampy forests and meadows of northwestern Asia are found the grassy steppes of Siberia. They are best likened to the Great Plains of the western United States and extend as similar formations into European Russia. They gradually give way toward the south to the desert formations of Turkistan. Eastward the steppes extend far into Dzungaria and across northern Mongolia, ascending the highlands of Siberia. There the grass grows longer and makes better pasturage.

Northeastern Asia.—In this area high mountains intercept some of the most severe northern winds and allow the better saturated winds from the Pacific to exert a more benign influence on the climate. Hence a more luxuriant flora of a cold-temperature nature is found. It is composed largely of the same genera as occur in Europe and northern North America. Below lichen moors on the edge of the northern plateau in the Okhotsk region are dwarfed forests of hardy northern trees with coniferous forests at the lower levels. Tundra outliers are evident along the coast, but the deciduous forests of farther south are lacking. In Amur and the maritime provinces of Kamchatka, Sakhalin and Hokkaido extensive deciduous broad-leaved forests may be found interspersed with coniferous forests, especially at higher altitudes. Throughout the area are distinctive north temperate meadows with a varied flora, especially noteworthy being tall umbellifers.

Eastern Asia.—This region extends from Manchuria to Indochina and from the edge of the Tibetan plateau to the Japanese islands. The temperate deciduous forests of farther north reach down to the Shantung plain and give way toward the west to the desert vegetation of Mongolia. Oak, elm, ash, walnut and many other trees are found. Some hardy bamboos survive in Korea. Mongolia is the eastern end of the central Asiatic desert region and owes its dry condition to the inability of the summer monsoons to penetrate far inland because of the mountain chains that fringe

its southern and eastern borders. The better, though by no means abundant, vegetation of the loess region, which lies below the Yellow river and north of the mountain ranges extending east from Tibet, is the result not primarily of greater precipitation, but of the greater water-holding capacity of this richer and finer soil. Central China, comprising largely the Yangtze valley and including most of the Yünnan plateau, contains much of the rich and distinctive warm temperate flora which characterizes eastern Asia. A similar type of flora is also found in central Japan. This central China area is cut off by mountains from the severe northern influences and is bathed by summer monsoons from the China sea. The irregular weather of the northern part frequently results in droughts which profoundly affect the vegetation and the conditions of human life. The southern portion of this middle area contains a larger proportion of more southern plant forms, such as broad-leaved evergreen trees—laurels and banyans—which are absent in the north. Members of preponderantly tropical families such as the tea (Theaceae) and mahogany (Meliaceae) are also found. The natural vegetation throughout much of China has been highly altered during centuries of human exploitation by a dense population. In the west, bordering the high interior plateau, remain unexploited forests, passing from temperate deciduous trees upward through various zones of coniferous forests to dense rhododendron thickets below rich alpine meadows with primulas, poppies, asters, etc. Living trees of the dawn redwood (*Metasequoia glyptostroboides*), previously known only by fossil specimens, were discovered in 1945 in a few moist valleys of central China. The subtropical vegetation of southern China extends northward along the shore of the China sea east of the coastal mountain range as far as Chekiang province, and on to Formosa and southern Japan. Apparently much of the lower land once supported tropical or subtropical evergreen rain forests, which may still be found on Hainan. There now exist largely bare deforested and grass-covered hills with at best a meagre secondary type of savanna forest.

Southeastern Asia.—The continental portions of this region have a tropical climate and are wholly monsoon controlled. The monsoon type of tropical deciduous forest is found at its best at medium altitudes. Teak is one of the principal components and Dipterocarpaceae (*q.v.;* a family of timber- and resin-yielding trees) abound. These forests are limited below by evergreen lowland forests which result from a greater soil saturation, and at higher altitudes by evergreen rain forests. The mountain ranges that intervene between the great rivers which diverge from the narrow gorges of western Yünnan cause diverse conditions. The Malay peninsula is covered with dense tropical rain-forest jungles, reflecting the higher humidity and greatly lessened influences of the dry monsoons. There the vegetation is composed very largely of wholly tropical genera and families. Especially noteworthy are palms, rattans and tropical orchids and members of the Leguminosae, Euphorbiaceae, Rubiaceae, Annonaceae, Melastomaceae and Moraceae (*qq.v.*). The Malay archipelago and the Philippine Islands have a fairly homogeneous tropical flora diversified by altitudinal changes in climate with generally drier types of vegetation on the sheltered sides of the islands, which are more or less monsoon controlled. Certain mountain ranges extend above the tree limit and show a floristic similarity to the eastern Himalayan region. There is a generally decreasing humidity with less luxuriance of vegetation eastward from western Java.

Southern Asia.—High-mountain and temperate floras predominate in the Himalayas beyond the maximum influence of the monsoons. In this area are found forests of oak, characteristic conifers, rhododendrons and rich mountain meadows, extensions of the vegetation of far western China but with significantly different species. In the eastern Himalayas and Assam occur some of the heaviest rains and densest evergreen rain forests in the world. The vegetation varies with increasing altitude, beginning at the coast with rich swampy jungles and ending in mountain meadows and shrubby stony slopes around 16,000 ft. In a large part of India the more or less prolonged dry season results in a tropical deciduous savanna (parklike) type of forest, of which teak and *Shorea robusta* are prominent members. The vegetation in many parts of India is as highly altered by exploitation as it is in central China. Its original character can only be surmised. Peninsular India has a dry interior plateau with a semidesert type of flora rich in thorny trees and shrubs, especially acacias. More luxuriant forms of vegetation occur in the dissecting valleys, where water is more abundant. There the sandalwood tree is at home, although it was probably introduced long ago from the Malay islands. The Malabar coast, a very humid strip backed by the highest mountains (8,800 ft.) south of the Himalayan chain, contains evergreen rain forests with genera and families of plants scarcely represented elsewhere but with some elements in common with the Malayan region. Much of the east coast of the Deccan peninsula has a semievergreen flora with a considerable proportion of thorny species. The estuaries on both coasts, as well as on the other shores of the Bay of Bengal, have extensive mangrove swamps.

Ceylon should naturally be covered with forests, but there are now extensive areas of savannas, grasslands and fernlands of secondary origin. The western Himalayan flora is less rich than the eastern and lacks many of the tropical and certain of the temperate genera found in the latter. It includes, however, some European genera, principally representatives of the Mediterranean flora. Thus the deodar (a cedar) is found there, but larch, common in the east, is lacking. The plain of the northwestern part of the Indian subcontinent is dry and desertlike, with a corresponding flora. It is, indeed, only an arm of the great arid region of southwestern Asia. Its dryness is mitigated by extensive irrigation from the snow-fed Indus river.

Southwestern Asia.—Most of this area from Asia Minor and Arabia to the western margin of Tibet and the Kirgiz steppes is desert or steppe, except where the mountain ranges are high enough to intercept the more northerly winds and rob them of their meagre moisture. Where the larger rivers, such as the Tigris and Euphrates, traverse broad valleys the desert can be made to grow productive crops.

The flora of Arabia is poor in the number of species, and plant communities consist of large numbers of plants of only two or three species. They are strikingly pale green, gray or even whitish.

The Mediterranean flora of characteristic gray-green aspect, such as the olive and evergreen oak, stretches eastward from the shores of Asia Minor, especially along the well-watered northern slopes of the Black sea and on across northern Iran and the southern Caspian coast to Afghanistan and the western Himalayas. The mountains likewise bear coniferous forests of distinctive species.

Northern Iran is a better watered region where deciduous forests occur, as in Europe, but they are composed of a larger number of species. An extensive growth of box scrub is found at higher altitudes in certain places. The chief characteristic of the Iranian flora is the preponderance of thorny and prickly plants, of which more than 500 species have been counted, various kinds of *Astragalus* being among the most noteworthy. The sand wastes and salt tracts in the desert plains support characteristic vegetation, as tamarisk bushes, saltbush and wire grass. Date palms, however, occur in the oases.

The flora of Russian Turkistan reflects the cold desert conditions which prevail in this plain, cut off by high mountains on the east and south. One of the principal desert plants is the saxaul of the Chenopodiaceae, a family especially well represented in the desert vegetation of inner Asia. Vegetation sufficient to support human life is confined to the vicinity of the two rivers which flow from the mountains into the Aral sea and to the strips along the mountains where irrigation has permitted the growth of cities and centres of culture.

In the mountainous highlands of Russian Turkistan occur coniferous forests of an open parklike character, bordered above and below by grassy meadows. Flocks come there when the heat of summer dries up the pastures lower down.

Central Asia.—The vegetation of this high and dry plateau, which is divided by mountain chains into several basins, is very meagre. The great height of the plateau and its northern location result in extremes of daily and seasonal temperature, so that the plants which survive are of the hardiest types. The vegetation is arranged roughly in concentric zones about the most sterile sandy wastes and salt tracts. Extensive swamps occur, backed by better-

drained grasslands and thin scrub formations. The streams are often bordered by willows, poplars and elms. Eastern Tibet is partly grassland. Toward the northern side of this plateau the vegetation is composed of more northern elements, but in the south there are more genera and species related to the Himalayan flora. Characteristic mountain forests are found in the Pamirs, where the mountains converge toward the west. (W. B. T.)

E. Animal Life

It is obvious that the animal life (fauna) of a large continent such as Asia, ranging from inside the Arctic circle in the north to well into the tropics in the south, and from the arid Arabian regions in the west to the rain forests of the Malay archipelago in the east, must be very diverse. If climate were the only factor controlling the distribution of animals, a gradual change of the fauna from north to south would be expected. However, the Himalayas, stretching from west to east, form a barrier which prevents many northern animals from dispersing southward as well as many southern animals from extending their range northward.

The part of Asia north of the Himalayas, Iran, Asia Minor and Israel belong to what is called in zoogeography the Palearctic region. This region includes the whole of Europe and the Mediterranean countries of Africa. Asia south of the Himalayas is called the Oriental or Indian region. The boundary between the Palearctic and the Oriental regions east of the Himalayas is not well marked, as there the mountain chains often have a north-south trend, facilitating instead of preventing the migration of the Palearctic fauna southward and of the Oriental fauna northward.

Palearctic Region.—The Palearctic fauna of Asia is by no means uniform. Distinction can be made between a tundra fauna in the north, followed southward by that of the taiga, the belt of coniferous forests bordering the tundra to the south, which again merges into the steppes with a fauna of their own. In the tundra the deeper soil remains frozen the whole year round, hence burrowing animals cannot live there and, as the tundra is partly free from snow only during the short summer, conditions for life are poor. Most of the animals, such as reindeer, arctic hare, arctic fox and wolf, occupy this region in summer only and migrate southward in autumn, but the lemmings stay there and remain active under the snow, feeding on the buried herbage. Hibernation, as is the rule for many animals in countries with a cold winter, is impossible in the tundra, for the short summer does not allow the necessary accumulation of food reserve in the body.

Birds also desert the tundra in winter but here too there is an exception—the willow grouse and the ptarmigan live in tunnels in the snow, feeding on berries. During the summer birds are numerous. Many species of waders which in Europe are known as migrants only, such as the gray plover, sanderling, knot and several kinds of sandpipers, breed there, feeding principally on the mosquitoes which occur in the wet parts of the tundra in enormous numbers. These insects also form the staple food of the passerine birds that breed in the tundra, such as the snow bunting and the Lapland bunting. Peregrine falcons, rough-legged buzzards and skuas prey on these smaller birds, but principally on lemmings. Several kinds of geese and ducks, arctic tern and black-throated and red-throated divers occupy the moist parts of the tundra.

The taiga fauna is much richer than that of the tundra. This is the haunt of the brown bear, wolf, glutton, otter, ermine, sable, lynx, elk, forest reindeer, hare and several kinds of squirrels. Among birds, capercaillie, black grouse, hazel hen, black woodpecker, greater and lesser spotted woodpeckers, three-toed woodpecker, pine grosbeak, crossbill, siskin, redpoll, red-spotted bluethroat, rubythroat, redwing, fieldfare, nutcracker, Siberian jay and many others inhabit these forests, and where marshes and pools occur the terek sandpiper, oyster catcher, green and wood sandpipers and several other waders may be found.

The rivers of northern Asia are inhabited by many fresh-water fishes which are common in European inland waters and, besides, by several kinds of sturgeons, among them the sterlet. Lake Baikal has a peculiar fauna, including many native species of sponges, worms and crustaceans and a native species of seal.

The fauna of the steppes differs as much from that of the taiga as that of the tundra. There many burrowing rodents occur such as jumping mice or jerboas, marmots and piping hares (*Ochotona*). The large grassy plains are the home of antelopes. Typical birds are the bustards, quails, sand grouse and the red-legged hobby. Hoopoes and rollers are common locally, and where the banks of rivers offer convenient nesting grounds, bee eaters and the common sand martin may be found. Enormous reed beds lie along the courses of the great rivers, and these are inhabited by waterfowl of many kinds, and also by a locust. Certain conditions give rise to a migratory phase in these locusts when they swarm out in incredibly large numbers and start their devastation of crops.

The mountains and the plateau to the north of the Himalayas have a mountain fauna which partly reaches the Himalayas proper. Many kinds of wild sheep and goats live there. Tibet is the home of the yak.

The eastern part of the Palearctic region—Manchuria and eastern China—has several peculiar kinds of deer. The giant panda inhabits parts of China bordering Tibet; the lesser panda is a Himalayan animal. From the wastelands of the higher Himalayas came many legendary accounts of the "abominable snowman" (*q.v.*).

The large rivers of China have a rich fish fauna among which *Psephurus gladius* from the Yangtze and Yellow rivers is of interest, as it is one of the two survivors of an otherwise extinct family, the other being the paddlefish (*Polyodon spathula*) of North America. Another fresh-water animal, its nearest relative living in North America, is the giant salamander (*Megalobatrachus*) from Chinese and Japanese waters.

The Japanese fauna has many species identical with or closely allied to continental Palearctic species, but also peculiar species, such as a monkey allied to the Gibraltar monkey and a mountain goat allied to the serous (*Capricornis*) from the Himalayas and western China.

The fauna of Asia Minor (*q.v.*) is much like that of other Mediterranean countries but Israel, Syria and Arabia have an African element in their fauna, such as a species of coney (*Procavia*) and, in Lake Tiberias and the Dead sea, fishes of the African genus *Tilapia*.

Oriental Region.—For its greater part the Oriental region is situated inside the tropics. The northwestern part is dry and partly even desert, where the fauna is poor. The northern part, south of the Himalayas, has dry, cool winters and very hot, wet summers. In the southern part of the Indian peninsula and in the southeastern peninsula (Thailand, Indochina and Malaya) and in the Malay archipelago the temperature is nearly constant, seldom rising above 30° C. (86° F.). These are the regions where tropical rain forests prevail. Monkeys are common, but apes are found only in the rain forests, being represented by gibbons in Assam, Burma, the southeastern peninsula and the Greater Sunda Islands, whereas the orangutan is restricted to Sumatra and Borneo. Among carnivores the lion is now confined to the Gir forest of the Kathiawar peninsula, where it is protected. The tiger ranges from the Himalayas to Sumatra, Java and Bali. It is absent from Borneo and from Ceylon. Panthers range all over the Oriental region, but have never been found in Sumatra. Civets and mongooses are numerous; the latter do not extend their range so far to the southeast as the former, some species of which even inhabit the Moluccas. Among badgers the ratel (*Melivora*) lives in the hilly districts of peninsular India but its range goes as far westward as Israel. Jackals are plentiful in India; the striped hyena is confined to drier parts. Both are absent from the eastern part of the Oriental region. Flying and ordinary squirrels are common in forests and woodland. The gaur (*Bibos gaurus*) is an inhabitant of the larger hill forests of India and Burma, the banteng (*Bibos banteng*) lives in the lighter forests of Burma and south to Borneo and Java, but it is absent from Sumatra. The most common antelope is the black buck which may be found in bushes and cultivated plains all over India, except the Malabar coast. The nilgai (*Boselaphus tragocamelus*) and the four-horned chousingha (*Tetracerus quadricornis*) occupy the hilly regions south of the Himalayas. There are several species of deer in the Oriental region. The musk deer lives in the pine zone of Kashmir,

Nepal and Sikkim; the sambar deer and its allies are distributed practically over the whole of the region; the barking deer also has a wide distribution, ranging northward into China. Typical beasts are the chevrotains (*Tragulus*) and wild boars are widely distributed. The Indian one-horned rhinoceros is at present confined to Nepal and Assam; the Javanese rhinoceros, too, formerly had a wider distribution but its range is now restricted to Malaya, southern Sumatra and western Java, and the two-horned rhinoceros ranges from Burma to Sumatra and Borneo. The Indian tapir is an inhabitant of dense forests in southern Tenasserim, Malaya and Sumatra. The Indian elephant can be found in suitable places throughout the Oriental region, including Ceylon and Sumatra. Scaly anteaters or pangolins are characteristic, but occur also in Africa.

Among the many birds which inhabit the Oriental region, game birds play an important part. The Indian peacock is met throughout India, whereas another one is restricted to Java. Numerous species of pheasants live in the forests of Burma, Thailand, Indo-china, Malaya, Sumatra and Borneo. Jungle fowl are found only in the Oriental region. Pigeons occur in great variety, but the number of species of parrots is small as compared with that of other tropical regions; the most conspicuous one in India is the rose-ringed parakeet, replaced to the east by the moustache parakeet. Water kingfishers as well as wood kingfishers are represented by many species. Hornbills, although not restricted to the Oriental region, show their greatest development there. The Indian hoopoe is rather common in India but is only met as a migratory bird in the southeastern part of the Oriental region. Among cuckoos the brain-fever bird is well known. Eagles, ospreys, falcons, hawks, kites and buzzards all occur, and in the western part vultures are numerous and can be found even in towns. The forests are inhabited by many species of woodpeckers. The barbets are characteristic, the best-known being the coppersmith bird. Bee eaters and rollers are common in India, but whereas the former can be found as far as the Malay archipelago and beyond, rollers are absent from the southeastern part of the Oriental region but reappear again in Celebes. The passerine birds are too numerous to survey at length. The house crow, the Indian grackle and the common mynah are familiar birds in India. Drongos, flycatchers, bulbuls, tailorbirds, orioles and many others are widely distributed and broadbills (Eurylaimidae) are typical birds. Many passerines, such as swallows, pipits and wagtails, have both resident and migratory species and the same can be said of many plovers, gulls, terns, ducks, storks and herons. Among the last named the cattle egret is a common bird in suitable localities all over the Oriental region, whereas spoonbills, cranes and gulls are confined to the western part.

Of the crocodiles the gavial is restricted to the large rivers of northern India, a species of an allied genus is found in Sumatra and Borneo and the mugger and the estuarine crocodile have a wider distribution. Fresh-water turtles and land tortoises are well represented. Lizards are numerous, including geckos, skinks and monitors, and flying lizards (*Draco*) are typical of the region. Chameleons are chiefly African, but one species is found in peninsular India and Ceylon. Snakes are numerous too, among them the poisonous krait, cobra and Russell's viper. Frogs and toads belonging to several families are abundant. True tree frogs (Hylidae) are absent, but some species of other families have taken to an arboreal mode of life.

The fresh-water fish fauna of the Oriental region is rich. The carp and catfish families have many native genera and species. The labyrinth fishes, to which the climbing perch and the gurami belong, and the spiny eels (Mastacembelidae) are characteristic of this fauna, although a few species live in Africa.

Insects, arachnoids, mollusks and other invertebrates inhabit this region in great numbers. The large and gorgeous bird-winged butterflies (*Ornithoptera, Troides*), allied to the well-represented swallowtails, are typical, although they occur in the Australian region as well. Almost all known families of scorpions are present. Among land shells the absence of Helicidae, common in the Palearctic region, is noteworthy. Their place is taken by other forms, such as *Hemiplecta,* and by operculate land mollusks.

(L. F. De B.)

II. NATURAL RESOURCES

Stretching from near the north pole to south of the equator, possessing some of the driest as well as the wettest regions of the world, the coldest as well as the hottest, and embracing rocks of every age and type, Asia has natural resources which are understandably varied. Its soils include the alluvium of the teeming rice-growing deltas of the monsoon lands, the arid expanses of southwest Asia and West Pakistan where snow-fed rivers enable the desert to bloom, and the fertile black earths of the Russian steppes. In mineral resources Asia holds an enviable position. Reserves of almost every important mineral occur and much of its wealth has yet to be surveyed and developed.

For convenience Asia can be divided into six major regions, each having some degree of homogeneity whether of culture, po-

FIG. 3.—PRINCIPAL LAND-USE REGIONS OF ASIA

litical regime or state of economic development. These regions are: Asiatic U.S.S.R.; southwest Asia (including Afghanistan); India-Pakistan; southeast Asia with Indonesia and the Philippines; China (including Tibet and the inner provinces and Formosa) with Mongolia; and Japan and Korea. It should be noted that information regarding resources in the U.S.S.R. and China comes mainly from government sources and can rarely be checked independently.

Asiatic U.S.S.R.—The great size and climatic variety of this region are reflected in the range of soil types. Tundra soils, peaty and overlying a frozen subsoil, occur along the Arctic coast and more extensively east of Lake Baikal. Podsols are developed over great areas in Siberia, often sandy and marshy in the west Siberian lowland, sometimes stony on the central Siberian plateau. Some podsols lie on permanently frozen subsoil in northeast Siberia. Gray podsolic forest-steppe soils mark the southern limit of the podsols and the beginning of the unleached pedalfer soils in the chernozem (black-earth) belt which extends in a narrowing zone from the southern Urals east to the Ob river and then in isolated patches close to the southern frontier of the U.S.S.R. These are important agriculturally; *e.g.*, Minusinsk steppe and areas in the upper Angara valley, and near Chita farther east. With increasing aridity the chernozem gives way southward to chestnut soils in the Kirgiz steppe and then to brown desert-steppe soils with extensive tracts of sandy desert. On the Caspian coast are areas of salt marsh and solonchak (saline soils). In Transcaucasia there are dark brown podsols developed under moister conditions and a small patch of subtropical red-yellow earths on the Black sea coast.

Water resources for irrigation are of particular importance along the Syr- and Amu Darya rivers in Soviet central Asia. Rivers have been harnessed for hydroelectric power at several stations in the same region and in Transcaucasia, but the greatest potential probably lies in the rivers of southern Siberia. Oil and coal are the main sources of energy, however. There are oil fields on the eastern and northern shores of the Caspian near Krasnovodsk and along the Emba river. The Fergana valley field in central Asia is of some importance, and small fields are worked in the Lena basin (Yakut Autonomous Soviet Socialist Republic) and on the island of Sakhalin. Coal is of more immediate industrial value. The Kuznetsk basin in west Siberia is the Soviet Union's second in production and supports a major industrial region. The Karaganda field in Kazakhstan provides coking coal for metal industries in the Urals. In east Siberia the Irkutsk field and in the far eastern region the Bureya and Vladivostok fields are of value to local industry and to traffic on the Trans-Siberian railway. Lignite deposits in the central Asia republics and west Siberia are of minor significance but vast coal fields are thought to underlie the Tunguska and Lena basins.

Other mineral resources are considerable, even if the varied wealth of the Urals is held to be conventionally in Europe. The Soviet Union's principal source of uranium is in central Asia at Tuya-Muyun. Iron ore is mined in the Kuznetsk region and at Khabarovsk, both areas supporting iron and steel production. Of the ferroalloys, manganese is found in the Kuznetsk basin and in Kazakhstan, which also has large chrome deposits, cobalt and molybdenum; the latter occurs in several localities east of Lake Baikal. Tungsten is mined in southern Siberia, vanadium in the Kirghiz A.S.S.R. Nonferrous metals are widely distributed and few are unrepresented. Kounradski on Lake Balkash is a major copper producer and there are half a dozen other mines in Kazakhstan, central Asia and west Siberia. Tin is found near Chita, east Siberia. The Kuznetsk basin has the Union's main lead-zinc ore complex and more is mined in Kazakhstan and in the far eastern region. Nickel is mined at Norilsk within the Arctic circle. Aluminum minerals are found at Akmolinsk (Kazakhstan) and in the Kuznetsk basin. The Lena valley is probably among the world's chief sources of gold. Other minerals worthy of note are mica, asbestos, mercury, beryllium and silver.

With such a plethora of resources, it is not surprising that industry has developed rapidly at a number of centres, especially under the stimulus of wartime necessity when much of the U.S.S.R.'s European industry in the Donets basin (Donbas) and elsewhere was overrun by the Germans. However, production is still secondary to that of the European part of the U.S.S.R. The Kuznetsk basin is important for heavy industry of many kinds but engineering is widespread in towns along the Trans-Siberian railway and in Soviet central Asia. Textile industries are concentrated in the latter area and in Transcaucasia but are also found in the Kuznetsk basin, Irkutsk and in other large towns.

Of all the countries of Asia the U.S.S.R. probably has the greatest area of productive forest, almost all of it coniferous softwood. The taiga forest stretches across the whole of Siberia, flanked by the steppe grasslands to the south and by the bleak tundra strip to the north. Forest exploitation is mainly along the Trans-Siberian railway and navigable rivers accessible to it or, like the Yenisei, penetrable from the Arctic sea during the brief summer. Lumbering is important also in the far eastern region in the vicinity of Vladivostok.

Agriculturally, as industrially, Soviet Asia is something of a colonial territory compared with its European counterpart and still contains virgin land suitable for development. The black-earth belt, especially the Barnaul steppe, is one of the Soviet's surplus grain areas. Wheat, rye and oats (the latter notably in east Siberia where the growing season is short) are the food grains. Cultivation is generally extensive rather than intensive. Projects for increasing agricultural production by cultivating the virgin steppelands have concentrated attention on the chestnut-soil belt on the semiarid southern margins of the black earths. Irrigated cotton is the main industrial crop in Soviet central Asia and Transcaucasia, sunflowers for oil in the black-earth belt and some flax on its northern fringe. The drier steppelands support sheep and goats, as do mountain pastures, while cattle are associated with the agricultural areas and reindeer herding with the tundra and more open taiga. Grapes grow well in Transcaucasia and in irrigated gardens in central Asia, and the sheltered subtropical western corner of Transcaucasia has a small area of tea plantations.

Southwest Asia.—As most of this region can be regarded as semidesert and desert, except for its northern and western fringe, water resources are of the utmost importance to agriculture and pastoralism. Apart from Turkey, where the need is less pressing, water resources are used very intensively. Well over half the agricultural area of Iraq is irrigated by the Tigris-Euphrates system, while in Iran the irrigated area comprises lands in a great number of internal drainage basins. Syria, Lebanon and Israel irrigate from 12% to 20% of their cultivated land, and would include more if water were available. Long summer drought causes river regimes to be very irregular, militating against their use for power production. Syria (Yarmuk river) and Turkey generate hydroelectric power on a small scale.

The region is fortunate however in its resources of oil and coal. Turkey, with little oil, has a valuable coal field supporting industry around Zonguldak. Iran mines coal near the Caspian coast, and Afghanistan north of Kabul. Oil is of immense importance but chiefly as a source of foreign exchange. Iran and Iraq have extensive oil fields in the foothills of the Zagros mountains but the more recently developed fields on the Arabian shore of the Persian gulf in Kuwait, Bahrein, Qatar, etc., are even more productive. The countries on the Mediterranean coast have neither oil nor coal.

Turkey is most fortunate in possessing a variety of minerals. Iron ore from Divrigi is smelted at Karabuk close to the coal field; manganese is found at Eregli and on the Mediterranean coast. Turkey ranks first in world production of chrome, of which Afghanistan has small reserves. Copper is mined at Madan (Turkey) and a little gold in Saudi Arabia. The rest of the region is poor in metalliferous minerals but among nonmetals mention should be made of the Dead sea potash, sulfur in Turkey and phosphate rock in Jordan. As, however, much of southwestern Asia has been little explored it is quite possible that further resources will come to light.

The countries bordering the Mediterranean have about one-fifth to one-quarter of their area under cultivation but eastward in Afghanistan the proportion falls to under 2% and is negligible in Saudi Arabia. Much uncultivated land is of value as grazing for sheep and goats and seminomadic pastoralism is the way of life

over wide areas of semidesert. Turkey and Syria, with agriculture supported by rainfall to a large extent, and Iraq with its irrigated plains normally export a surplus of agricultural products, notably wheat. This is the main food crop, but barley takes first place in Iraq and Israel. Maize and rice are also grown, the latter as an irrigated crop in Iraq, Turkey and on the Iranian shores of the Caspian sea. Turkey, Iran and Israel grow sugar beet but cotton is a more important industrial crop, especially in Turkey, Syria, Iran and Iraq. The cotton-spinning industry is established in a number of centres in Turkey, Syria, Lebanon, Israel and Iran and in the capital cities of Iraq and Afghanistan.

Citrus fruits are Israel's principal export, important too in Lebanon and Syria, while Iraq produces four-fifths of the world's dates. The latter grow in Arabia wherever water is available. Grapes are grown on a large scale to be dried as raisins in Turkey and Iran. Dried figs are exported from Turkey, where tobacco is locally important, and olives are grown on the Mediterranean coastlands. The climate of the region is against the rapid growth of forests which are extensive only in the better watered mountains of Turkey and Iran, particularly around the Caspian.

India-Pakistan and Ceylon.—An authoritative soil survey of India-Pakistan has yet to be made. The Indian states of Rajasthan, Uttar Pradesh and Punjab, with the whole of West Pakistan, have mainly dry steppe soils with a saline tendency toward the margins of the Thar desert. The eastern part of the Ganges valley has prairie soils giving way to young alluvial soils in the delta. Over most of peninsular India red soils are developed on Archean rocks while the Deccan lavas give rise to the characteristic black sticky regur. Laterites are found capping the Western Ghats and on parts of the Bastar hills and Chota Nagpur plateau. The Shillong plateau and some "older" alluvium in Bengal bear red-yellow soils best described as lateritic.

To the peasant agriculturalist the workability of the soil, its water-holding qualities and the possibilities for irrigation are more immediately significant facts than those concerning its chemistry and genesis. The soils of the Indo-Gangetic plain and of the more restricted valley plains and deltas of the peninsular rivers are thus agriculturally of outstanding importance. Except on the moisture-retentive regur soils, agriculture on the uplands is generally poor and of very secondary importance. The concentration of rainfall in the summer months, followed by three to six months of drought, emphasizes the importance of irrigation. There is hardly a corner of the subcontinent that would not benefit from an assured all-season water supply, but this has only been attempted in the northwest in many areas of which agriculture would otherwise be impossible. The great rivers rising in the Himalayas and fed in the dry season by melting snows bring life-giving water to the plain of the Indus and its tributaries and to the Ganges system. Their waters have been extensively controlled and utilized for irrigation. In some saline-soil areas in the Indus basin seepage of water from canals and overirrigation have caused alkali efflorescence rendering the land unusable. The regime of the peninsular rivers, lacking snow fields as a dry-season reservoir, is highly variable. Many of them dry up just when their waters are most needed and the major existing irrigation systems distribute floodwater rather than storing it for dry-season use. There and in Ceylon there are numerous crudely embanked shallow tanks storing floodwater, but they rarely outlast the dry season and command only small areas. Some large multipurpose river-development schemes were in hand in the mid-20th century to increase the irrigated area. Innumerable wells by which ground water can be brought to the surface supplement canal irrigation in the northern plains. These are most important in the submontane belt in the Punjab and Uttar Pradesh, but deeper modern tube wells are increasing in number on interfluves beyond the command of canals. All told, about 10% of the area of India-Pakistan is irrigated, more than half of this by canals.

The rivers of the subcontinent are of great value as sources of hydroelectric power. The abrupt descents of the Western Ghats, Nilgiri and Cardamom hills have been so utilized for several years but the potential of the Himalayan rivers has been relatively neglected, Malakand and Mandi being for long the only stations. Since attaining independence, India, Pakistan and Ceylon have set about developing hydroelectric resources to feed new industry. In West Pakistan the Jhelum river has been harnessed and an ambitious multipurpose scheme is at Warsak on the Kabul river. In East Pakistan the Karnafuli river project is designed to produce 80,000 kw. India's schemes are mostly designed to control floods and to provide irrigation water at the same time as power. The Bhakra-Nangal project on the Sutlej river is one of the biggest constructions, but others have been completed on the peninsular rivers, *e.g.*, Damodar, Mahanadi, Tungabhadra (tributary of the Krishna), and in Ceylon the Gal Oya. In these schemes water storage over the dry season is a major problem.

India's coal resources are relatively abundant compared with those of Pakistan. They are concentrated in the northeastern part of the peninsula, in the Damodar valley particularly, where there are limited reserves of coking coal. In Assam and West Pakistan there are poor-grade, mainly Tertiary coals. Petroleum is found in the Digboi field of Assam (insufficient for India's needs) and in the Attock field of West Pakistan. Intensive search has failed to reveal further major oil fields but there have been important finds of natural gas in both West and East Pakistan.

India's reserves of iron ore, mainly high-grade hematite, and manganese are among the greatest in the world. Both minerals are found in the northeast part of the peninsula. West Pakistan has some inaccessible iron ore in Chitral and its only significant minerals are chromite in Baluchistan, rock salt, alum, gypsum and salts of magnesium and potassium, all in the Salt ranges. India is endowed with a variety of nonferrous metalliferous minerals: copper, lead, chromite, gold and bauxite are all worked in various parts of the peninsula. Salt is mined in Rajasthan but much is evaporated from sea water in Bombay and Madras states. India's production of mica from Chota Nagpur amounts to about 80% of the world's supply. Important deposits of the "atomic" mineral monazite are worked in Kerala. Ceylon lacks coal and oil and is very poor in other minerals also.

Between 50% and 60% of the subcontinent is cultivated, agriculture being the mainstay of the population. Rice, millets (bajra and jowar) and wheat are the staple food crops. Rice is dominant in areas of good rainfall (60 in. and higher), notably in Bengal, Assam and Orissa, the west coast of the peninsula and in Ceylon. On the east coast deltas, in Madhya Pradesh, Uttar Pradesh, and to some extent in Bihar, rainfall is commonly supplemented by irrigation, while in West Pakistan rice is grown irrigated in a near-desert climate. Drought-resistant millets are favoured in peninsular India but are also grown as an insurance crop in drier parts of the Ganges plain. Wheat, grown in the cool season, is the food crop of West Pakistan, the Indian Punjab and western Uttar Pradesh and is of some importance on the Deccan lavas. Various pulses and oilseeds are widely grown. Jute is confined to East Pakistan and adjacent West Bengal. Cotton is irrigated in West Pakistan but rain fed on the regur soils of the Deccan. More restricted in their location, but important in the export trade, are plantation crops. Assam, West Bengal, Sylhet (East Pakistan), south India and Ceylon have extensive tea gardens. Rubber is grown in Kerala and Ceylon; coffee in Mysore.

Pressure of population has caused the replacement of much original forest by agriculture or scrub jungle used for grazing, and productive forests are mainly limited to sloping areas. Even there, as in Assam, East Pakistan, parts of the Western Ghats and Ceylon, shifting cultivation prevents the optimum utilization of forests. The middle slopes of the Himalayas in the drier west bear valuable pine and deodar forests, while in the east are broad-leaved evergreen species with much bamboo, especially as secondary growth up to about 9,000 ft. Sal forest is dominant in the Siwalik hills and over the northeast of the peninsula. The Western Ghats and the hills bordering Burma have tropical evergreen and semievergreen forests including valuable teak, while the Sundarbans on the tidal fringe of the Ganges delta is a region of dense mangrove forest.

Except in India's heavy industrial region between Jamshedpur, the Damodar valley and Calcutta, and in the cotton textile dis-

FIG. 4.—PRINCIPAL MINERAL-PRODUCING AREAS OF ASIA

trict stretching north from Bombay to Ahmedabad, manufacturing is generally scattered. Calcutta shares the jute industry with the East Pakistan towns of Narayanganj, Khulna and Chittagong. Many large towns have textile industries and miscellaneous manufacturing often based on agricultural raw materials, foodstuffs, leather, etc.

Southeast Asia and Indonesia.—This region displays considerable soil contrasts ranging from the excessively leached lateritic soils of upland equatorial areas to the dry soils of central Burma. As far as man's utilization of the region is concerned, by far the most important soils are those developed on the alluvium of the several great and many minor delta plains. Next to these young alluvial areas the most productive soils are associated with basaltic lavas, widespread in Java and of some significance in South Vietnam. The more common acid igneous rocks and arenaceous sedimentary material generally give rise to soils poor in inorganic plant nutrients.

Mineral resources, exploited for export rather than for internal industrial development, fall into two main groups: the metalliferous minerals of the structurally older blocks of the Shan plateau, Malaya and southwest Borneo, and the petroleum fields of the belt of Tertiary folding surrounding this older core. The only important coal field is in North Vietnam, where anthracite is found, but Malaya, Sumatra and Borneo have minor deposits. From a global viewpoint oil is more significant. There are productive fields in Sumatra, Java and Borneo and in central Burma. Malaya and the Philippines have iron ore but there is no heavy industry in the region and the ore has been used in Japan. North Vietnam, Malaya, Java and the Philippines are minor producers of manganese. Ores of nonferrous metals, particularly tin, are of greatest importance. Malaya and Bangka-Billiton (Indonesia) rank first and third as world tin producers, Thailand was fifth and Burma was eighth; North Vietnam is also a producer. The Burmese centre of Bawdwin mines lead, zinc and nickel. Chromium is found in the Philippines (fourth world producer) and North Vietnam; bauxite and titanium in Malaya; the phosphate deposits of Cambodia have not been developed. The Philippines has a number of gold-mining districts but elsewhere, in Malaya, Sumatra, Thailand and South Vietnam, output is less important.

A major drawback to industrialization in the region is the lack of power installations. Water-power potential is considerable on the many rivers, great and small. The Mekong river could be harnessed to supply Laos, Vietnam, Cambodia and Thailand with electricity but capital funds and an assured market are lacking. Some hydroelectricity is generated in Malaya and Java but most of the small output of power comes from thermal generators in the major cities. Manufacturing regions do not exist, the principal industries being concerned with the processing of raw materials for export. Singapore smelts much of the region's tin ore. Java has a number of sugar mills. Textile industries making cotton goods for local markets are established in Burma, Thailand, Indonesia, the Philippines and North Vietnam.

Forests are relatively abundant in the region compared with the densely populated neighbouring countries. Burma and Thailand have valuable teak forests but the equatorial hardwoods of Malaya and the archipelago are little developed. Shifting cultivation with its periodic burning of the vegetation is responsible for reducing the quality of the forest cover in many areas, notably in Laos, Vietnam and Borneo.

The predominant agricultural activity is rice farming on the alluvial lowlands. The deltas of the Irrawaddy (Burma), Chao Phraya or Mae Nam (Thailand) and Mekong (South Vietnam) have long been major producers of rice for export, while in the Red river delta of North Vietnam and in Java rice cultivation has been even more intensive to support high densities of rural population. In Java and the Philippines hillsides have been terraced to grow rice and there are carefully tended systems of water control. Irrigation supplements rainfall in the drier parts, *e.g.*, central Burma and the Korat plateau of Thailand, and inundation canals are found on all the major river systems. Adequate storage provision has yet to be made for dry-season irrigation. Among the most important field crops after rice are tobacco (grown in all countries of the region but especially in Java), sugar cane (Java and the Philippines), soybeans (Java) and peanuts (Java and central Burma).

Plantation crops are of great importance. Malaya and Indonesia together grow most of the world's natural rubber and some is grown in South Vietnam and Thailand. The Philippines has a near monopoly of the abacá (manila hemp) trade and leads Indonesia and Malaya in copra production. The oil palm is increasingly popular in Malaya and Sumatra, which seek to diversify their plantation economy, while tea is a minor product of Java.

China and Mongolia.—About two-thirds of this region consists of the high plateaus and mountains of central Asia, much of it steppe and semidesert, where nomadic peoples rear sheep, goats and horses, exporting livestock and animal products, *e.g.*, hides, wool, etc., to lowland China and the U.S.S.R. Cultivation of

grains, mainly wheat, millets and barley, is restricted to irrigated strips along streams issuing from the mountains. Little is known of the mineral resources of this vast area but Mongolia mines some coal, iron, gold and nonferrous metals and oil fields are being developed in the Chinese provinces of Sinkiang and Kansu and in the Tsaidam basin in Tsinghai province. Mongolia has some engineering industries at Ulan Bator but is very dependent on U.S.S.R. manufactures. Urumchi (Sinkiang) and Lan-chou (Kansu) have textile mills. There are mountain forests in west Mongolia and Tibet but inaccessibility prevents their being of economic importance.

By contrast, eastern China with Manchuria has considerable resources. There are two principal soil types: brown podsols in north China grade inland with increasing aridity into chernozems developed on loess, while China south of the Tsinling Shan has the more tropical podsolic red earth. The north-south contrast is due basically to climatic differences which are also brought out by agricultural differences. In the north, wheat with drought-resistant millets and kaoliang, barley and soybeans are the principal food crops but the south and Formosa are dominated by rice. Soybeans incidentally are also a valuable industrial crop of which Manchuria produces a surplus. Along the Yangtze valley the rice and wheat regions overlap. Maize in the north and in Szechwan is a minor crop. The chief industrial crops are cotton grown widely in the north China plain and the middle Yangtze, and tea from the south China hills and Formosa. The tung-oil tree is of some importance in the south but the main sources of vegetable oils are sesame in the north China plain and rapeseed in Szechwan and central China. China leads the world in tung oil, sesame, rapeseed and soybean production. Peanuts, also in the north China plain, are another source of oil. The subtropical south China coast lines and Formosa grow sugar cane. Tobacco, for which China is second only to the U.S. in output, is grown extensively but particularly in Szechwan and the north China plain. Citrus fruits thrive in the south and in Formosa but rarely on a commercial scale.

Although large irrigation works were under construction by the middle of the 20th century on the Yellow river to protect the dry north from both flood and famine, small irrigation schemes command much of the cultivated land in south China. Everywhere farming is intensive and primarily for subsistence, though less so in Manchuria, an area of relatively recent agricultural colonization, where it is more commercialized. Intensive land use for agriculture and the demand for fuel and for grazing land has led to deforestation, until little real forest remains and that is confined mainly to the Tsinling Shan, the southern hills and the mountains bordering on Tibet and Burma. The mixed forests on the Greater and Lesser Khinghan ranges in Manchuria are, however, probably of greater economic significance.

China has long been recognized as possessing considerable hydroelectric power potential, particularly in its great rivers, the Yangtze and Yellow, and in the well-watered mountains of eastern Manchuria and southern China. Among important schemes completed or in hand in the 1960s were the Ta-feng-man (Sungari river) and Shui-feng (Yalu river) in Manchuria, and San-men on the Yellow river. There are also stations on the Yangtze near Chungking, on the Min river in the southeast and in Formosa.

Coal is likely to be of far greater value to China's industrial development, and China ranks second in estimated reserves of bituminous coal, including some good coking grades. Hardly a province lacks coal but the main field lies in the northwest in the provinces of Shensi, Shansi and Honan, a field comparable in extent with the American Appalachian field. Southern Manchuria and northern Hopeh have the largest production, but rapid development is taking place in Shansi. Of the southern coal fields the most extensive is in Szechwan. The principal iron-ore mines are in Manchuria near An-shan and Pen-ch'i. Other sources are Hsüan-hua or Suanhwa (Hopeh), T'ang-shan (Shantung), Ta-yeh and Ch'i-chiang (Kikiang) on the Yangtze near Hankow and Chungking respectively, and near Pao-t'ou in Suiyüan. The precise state of development of mining and manufacturing in China is not known. In certain key nonferrous metals China holds an important position, notably in tungsten and antimony, both mined in the south. Tin occurs in Yünnan, manganese in south central China, copper in Formosa and Manchuria, vanadium in the north, lead and zinc in the south and in Manchuria; generally, all these resources are on a small scale. Shantung, south Manchuria and Hainan have bauxite and Kiangsu produces some rock phosphate. Manchuria has a large output of magnesite, asbestos and gold, while gold and mercury are found in the south China hills. Mineral salt is obtained in Szechwan but much comes from evaporation of sea water.

With such a range of resources it is not surprising that despite a late start China is developing rapidly as an industrial power. Heavy industrial regions are concentrated in the north around An-shan, Pen-ch'i, Mukden, Harbin and Dairen in Manchuria, at Hsüan-hua northwest of Peking, inland at Pao-t'ou, at Wu-han on the middle Yangtze, at Chungking and at Shanghai. There is an increasing tendency for manufacturing districts to grow inland, especially near the major coal fields, but the textile and other light industries are still located mainly in the coastal cities such as Shanghai, Canton, Tientsin and Tsingtao, though important new centres inland include Cheng-hsien (Cheng-chow), Sian and Ch'eng-tu.

Japan and Korea.—These areas are alike in having rugged terrain and restricted development of plains. Soils are generally podsolic, tending to subtropical red in southern Japan, but agricultural methods are so intensive that water-holding capacity is of more importance than soil chemistry. Rainfall, especially in Japan, is adequate for plant growth but the traditional popularity of rice as the mainstay of farming makes irrigation important as a means to maximum yields. Only in North Korea is rice displaced by millets and wheat as the main food crop, though in South Korea barley is quite important; wheat and barley are becoming more popular in Japan as second crops after rice, and oats is a main crop in the cooler north in Hokkaido, though rice is grown there too. The principal commercial crops are cotton in Korea, mulberry trees (for silkworm fodder) and tea in southern Japan. Apples and pears grow in eastern Korea and northern Japan, citrus fruits and tobacco in the subtropical south.

In Korea mineral wealth includes low-grade iron ore, anthracite, tungsten, beryllium and lead-zinc in the north, molybdenum and some tungsten in the south; gold and fluorspar are also mined. Hydroelectric power is generated particularly in the north along the Yalu river. The main industries are cotton textiles in the south, rayon in the north using local timber resources. The north also had heavy metal and chemical industries, though these were interrupted during World War II and the Korean war.

Japan, after the U.S.S.R., is the most industrialized country in Asia but depends much on imported raw materials to supplement its own resources. It possesses several coal fields, the chief being in Hokkaido and Kyushu, and has a small output of oil from fields on the west coast of Honshu and Hokkaido. Water power is highly developed, the wet climate and mountainous relief there being an advantage, especially in central Honshu. Vulcanicity ensures the country an abundance of sulfur and pyrites, but except for widespread copper, and some chrome in Hokkaido, the great variety of the mineral resources are quite inadequate for Japan's industries. Thus it has a little iron ore, manganese, tungsten, lead zinc, tin, mercury, gold and silver.

Manufacturing is concentrated in a belt of cities extending from Tokyo west-southwest through Nagoya to Kōbe-Osaka on the shores of the Inland sea and the industrial cluster of northern Kyushu centring on Yawata and ending at Nagasaki. This belt includes both heavy and light industry. Outside it there is manufacturing on the Hokkaido coal field at Muroran and at Kamaishi on the iron-ore field in north Honshu. Heavy industry includes shipbuilding, heavy engineering, vehicles and chemicals, but Japan is better known in foreign markets for its textiles. Utilizing its own timber resources, Japan produces cellulose rayon and newsprint and has been an important supplier of cement to south Asian countries.

III. ANTHROPOLOGY

In this section the word anthropology is used to cover two aspects of the science of man. The first is cultural and depends on social inheritance or nurture; the second is physical and depends on biological inheritance or nature. Both may be affected by environment in the widest sense of the term. The study of culture is the province of archaeology, ethnology, social anthropology and linguistics. The archaeologist traces the spread of past cultures from what is left of their tools and other implements and art forms. The ethnologist does the same by comparing the cultures of present-day peoples. The social anthropologist studies the social institutions and related beliefs of peoples. The linguist, in establishing the relationships between languages, makes possible inferences about the previous connections of their speakers.

A major aim of the anthropologist is to reconstruct the biological and cultural history of mankind at all times and in all places. As documentary evidence is available to him for only a small number of cultures (and then is often confined to the most recent period of their existence), to fill in the blanks in space and time he draws upon the findings of paleoanthropology, anthropography, archaeology, ethnology and linguistics. Any discussion of Asia as an anthropological unit divorced from adjacent areas is necessarily artificial. Europe is properly only a western peninsula of Asia; Africa is linked with Asia at the isthmus of Suez; the American mainland may be seen from the eastern cape of Siberia; and the islands of Indonesia and Melanesia lead like steppingstones from southeastern Asia into Australia and Polynesia. As a result of this geographical propinquity the peoples of Europe, Africa, America and Oceania show, in varying degrees, physical, linguistic and cultural affinities with those of Asia. Within itself, moreover, Asia contains the widest variations in physical types and cultures of all the continents and a diversity of languages apparently exceeded only in the Americas. The intensive anthropological study of Asia is, however, only beginning. In proportion to its area and population, less anthropographic, linguistic and ethnographic research has been done in Asia than in any other continent. The consequent paucity of evidence permits only tentative generalizations. (J. C. Tr.)

A. Ethnology and Languages

The cultures of Asia may be grouped into six major areas, each of which occupies a more or less distinctive natural habitat. These culture areas are as follows:

1. Northern Siberia, comprising the treeless tundra of the northern coasts and lowlands and the forest zone or taiga. The basic subsistence pattern is fishing, the hunting of land and sea mammals and reindeer breeding. Social organization and technology are relatively simple.

2. Interior Asia, comprising the steppe zone, a transition zone of steppe-forest in the north, a central steppe-desert system and highland. This generally arid region includes Sinkiang or Chinese Turkistan, Russian Turkistan, Tsinghai province and northern Kansu, Outer and Inner Mongolia, parts of southern Siberia and Tibet. The traditional economy is nomadic pastoralism, with enclaves of farming where water is made available. Hunting is a subsidiary means of getting food, clothing and shelter. Some of the peoples of Turkistan depend on both herding and farming.

3. East Asia, comprising China proper, Japan and Korea. The territory of China within this area is that within the Great Wall, or monsoon China. Intensive agriculture is the predominant means of subsistence; peoples who live by other means are few and scattered. Manchuria is a crossroads of the Siberian, east Asian and interior Asian zones in both culture and natural environment.

4. The Indian subcontinent, comprising India, Pakistan, Ceylon, Nepal, Bhutan and Kashmir. The cultural range, like that of terrain and climate, is great. The predominant culture is Indic but variations are found in Pakistan, which is Moslem, in Buddhist Ceylon and among various indigenous tribes.

5. Southeast Asia, comprising the peninsular states of Burma, Thailand, Malaya, Laos, Cambodia and North and South Vietnam. Cultural relations there have not been as clearly defined as in the other areas. The broad cultural range within this wet, tropical region includes primitive groups with simple technology and social organization who live by fishing, hunting and collecting wild plants, as well as civilizations with intensive agriculture, fairly advanced technology, complex social and political organization and literary traditions.

6. Southwest Asia, comprising Afghanistan; Iran; the Arab states of Saudi Arabia, Syria, Iraq, Jordan, Lebanon, Aden protectorate, Yemen, Kuwait, Bahrein and Oman; Israel; and Turkey. Much of the region is desert; among the few well-watered zones are the "fertile crescent" (in James H. Breasted's phrase) region of northern Iraq, Lebanon and Syria, extending to northern Israel, and parts of the coast of Turkey. The Islamic people predominate save for the Israeli enclave, the Christian communities of Lebanon and minor sects. All the main branches of Islam are centred in the area. The inhabitants are predominantly agricultural but a significant portion of the populations of the Arab countries, Iran and Afghanistan are nomadic pastoralists and some groups combine cultivation and herding.

The cultures and languages of these six areas will be discussed in order.

Northern Siberia.—The indigenous inhabitants of central and northern Siberia fall into three main linguistic stocks: Uralic, Altaic (*q.v.*) and Paleo-Asiatic. The Uralic-speaking peoples include the Samoyed, Ostyak (Khanty), Vogul (Mansi) and Selkup in western Siberia and the Yukaghir of northeast Siberia. The Uralic groups are small; the largest of them, the Nenets of the Samoyed and the Khanty, each numbered fewer than 20,000 in 1926. Others range from a few hundred to a few thousand in size.

The Altaic stock is represented by two families in the area, the Tungusic and the Turkic. The most numerous of the Tungusic peoples are the Evenki and Eveni (Lamut). In addition, there are a number of small groups (Negidal, Udege, Oroki, Orochon, Olchi and Nanai or Gold) in the Amur river region in southeastern Siberia and northern Manchuria. There are two Turkic-speaking peoples, Yakut and Dolgan. The Yakut have moved north into the Siberian forest over a long period, primarily from the forest-steppe of southern Siberia, but also from east Asia. In Siberia they combined with indigenous peoples. The Yakut are by far the most numerous of the native peoples of Siberia, with a population of about 300,000. Their economy is chiefly the breeding of horses, cattle and, in the extreme north, reindeer. The Dolgan are a small group who are in the main Tungusic clans become yakutized.

The Paleo-Asiatic peoples form a residual category with no intrinsic unity other than membership in the north Asian cultural area and a generalized cultural resemblance. In northeastern Siberia they include the Eskimo, Chukchi, Koryak, Kamchadal (Itelmen) and Gilyak (Nivkhi). The genetic relationship of the Chukchi, Koryak and Kamchadal languages is well established. A suggestive hypothesis needing further exploration is the Eskimoan-Chukchian connection. The Gilyak have no known relation to the other northern peoples. The Ket (Yenisey-Ostyak) of western Siberia is a small remnant group unrelated to any of the others. Most of the groups number in the hundreds; the largest, the Chukchi, numbered about 12,000 in 1926.

The arctic and subarctic peoples share a number of traits in their technology, house types, clothing, food getting and religion. Their physical type is northern Mongoloid. The northerly habitat has played a central role in the formation of the material culture; the rigours of climate have limited the cultures to certain types. These boreal peoples place heavy reliance on furs and pelts for clothing and shelter. The dog is domesticated there as it is throughout Asia. None of these groups is limited to a single source of livelihood. The Chukchi are divided into two groups, the Maritime Chukchi, whose main subsistence base is the hunting of sea mammals and fishing, and the Reindeer

Chukchi, who depend on reindeer milk and meat for food and obtain clothing and shelter from the pelts and hides. The Evenki, the largest Tungusic tribe, are divided into sedentary and nomadic groups that live chiefly by hunting and fishing and by reindeer breeding, respectively. Some of the nomadic Evenki who live in the vicinity of the Mongols of southern Siberia (Buryat A.S.S.R.) and Outer Mongolia raise herds of horses and cattle. The Samoyed also have double-faceted economies.

The most widespread religion of the north Asian peoples is shamanism (*q.v.*), the basis of which is the establishment of close relations between the chief practitioner, the shaman, and a spirit. In invoking the spirit, the shaman induces a trance state through autosuggestion or narcosis. Shamans preside over religious rites and act as healers and seers. The basis of their supernatural powers is their intimacy with their spirits.

With the exception of the Yakut, who alone have traces of a past aristocracy, the social organization of these peoples is simple. They live in the forests and tundra, banding together in small camps or settlements. They have no writing, and their history prior to the 17th century must be pieced together from the few hints afforded by the archaeological record and oral traditions.

Russians moved into the area in large numbers from the 17th century on and have effected profound changes in the life of the indigenous peoples. (*See* CHUKCHI; GILYAK; KORYAK; OSTYAK; SAMOYED; TUNGUS.)

Interior Asia.—The indigenous populations of interior Asia are Mongols, Turks, Tibetans and Tajiks. Chinese are settled in Inner Mongolia, Sinkiang and Russian Turkistan. Their habitat, the steppe zone of Asia, extends from the mountains of western Manchuria to the Caspian sea.

Speakers of modern Mongol dialects are divided into three branches, eastern, western and northern. The eastern Mongols have their main seat in Inner and Outer Mongolia. The Khalkha Mongols dwell in Outer Mongolia; the Chahar, Ordos and others, forming the largest number of Mongol peoples, live in Inner Mongolia. The western Mongols or Oyrats live in the western parts of Outer Mongolia, Sinkiang and in the north Caspian plain, where they are known as Kalmucks. The Buriats, or northern Mongols, live in the vicinity of Lake Baikal in southern Siberia. There are small groups of Mongols speaking archaic dialects; the Monguor of Kansu, the Dagurs of the Amur river region and the Mongols of Afghanistan. (*See* BURYAT AUTONOMOUS SOVIET SOCIALIST REPUBLIC; MONGOL.)

Among the Turks, the Uygurs live in Sinkiang, Altai Turks in the Altai mountains and a number of small Turkic groups in southern Siberia, from the Tuva Autonomous Region to the Ural mountains. These are the Hakas, Tuvinians and Shori and others, whose names are taken from their locality, such as the Baraba Turks. There are a few peoples of Samoyedic origin who have become turkicized. Among these last are the Motor (Mator or Koybal) and Karagas (or Tofalar). In Russian Turkistan, the chief Turkic groups are the Kazakh, Kirgiz, Uzbek, Turkmen and Karakalpak. A small number of Kazakhs live in Sinkiang. Finally, a group of Turks known as Saryg ("yellow") Uighur (Uigur or Yogur) live in Kansu. In western Mongolia and in the Altai there are small groups of turkicized Mongols and mongolized Turks. (*See* TURKIC PEOPLES.)

The Mongols and Turks have both moved far to the west in a number of waves during the past 2,000 years. The Kalmuck Mongols have inhabited the north Caspian plain from about 1600. The Turks have moved west and south where they encountered the Iranian Tajiks, the prior inhabitants of what is now southern Turkistan. (*See* TADZHIK SOVIET SOCIALIST REPUBLIC.)

The Tajiks are a sedentary agricultural people. The Mongols are nomadic pastoralists by tradition, as are the Kazakhs, Kirgiz, Turkmen, Karakalpak, Altai Turks, Uzbeks and others of the Turkic peoples mentioned. The Uighur of Sinkiang farm the oases of the arid Chinese province; the once nomadic Uzbeks have taken up farming in the close neighbourhood of the Tajiks in recent centuries. Turkic pastoralists had a minor traditional dependence on farming, which is now of major importance.

The pastoralism of north Asia is simple; it is focused on the reindeer, except among the Yakut, who brought in cattle and horses from the south. The southern complex could not be maintained and all native pastoralism except reindeer breeding has declined in recent centuries. The pastoralism of interior Asia, by contrast, is more highly developed, involving herds of sheep, goats, cattle and horses. In the steppe-desert of interior Asia camels form as much as one-sixth of the herds; in the highlands the yak and a yak-cattle hybrid are raised; in the southwestern parts of the area (Uzbekistan, Turkmenistan) the donkey and the mule play a prominent role.

The agriculture of the Uighur, Tajiks and Uzbeks is intensive, with irrigation. The aridity of the steppe region limits farming to a few oases and river valleys, notably the oases around the Tarim basin of Sinkiang and the Fergana and Zeravshan valleys of Russian Turkistan. There, through careful use of water supplies, high yields of food grains and cotton are achieved. Agriculture is a supplementary source of subsistence for the Kazakhs, Turkmen and other Turkic nomads who cultivate small plots near their winter encampments. There is a small amount of farming on the slopes of hills and mountains, utilizing the seasonal floods of the melted snow. This form of agriculture, locally called *bugara*, is highly uncertain.

The Mongols had little farming in the past; considerable development of agriculture in Inner Mongolia followed Chinese settlement and influence. The Kazakhs, Kirgiz and other Turkic peoples have been settled in collective farms in the Soviet Union the change effected by official policy; but longer-range factors also influenced the change-over from pastoralism to agriculture. Chinese and Russian farmers moved into the steppe zone from the mid-19th century and settled in those lands with the best agricultural potentialities. These are at the same time the richest grasslands. The nomads were thrust back on the more arid wastes, which are their own reserves. The herders had to take up farming because of population pressures and limits on soil utilization as well as political policy. Farming is a more efficient basis of subsistence because it can support more people per acre than herding.

The Monguor of Kansu have been greatly influenced by Chinese culture. Their farming and social organization are Chinese and their political system has long been part of the Chinese system.

The Mongols have been Buddhist since the days of their great empires in the 13th century; of greater relevance to the present is their second conversion in the 16th century. The Turks are Sunni Muslims. (*See* BUDDHISM; ISLAM.) In both cases, the religions of higher culture origin have been combined with indigenous shamanist cults.

The organization of these peoples is complex. They have had a long tradition of hereditary nobility. Slavery was practised on a minor scale. The kinship system is based on patrilineal descent; family authority is vested in the patriarch; the son lives with the father in a common camp. The political institutions were evolved to a considerable degree but lacked stability during imperial times. However, the steppe peoples developed sporadic empires during the past 2,000 years, achieving a climax under the Mongol leader Genghis Khan and a second climax under the Ottoman Turks. These empires joined in a political unity herdsmen and farmers who had a crude sort of economic integration. Numerous smaller political enterprises preceded, accompanied and followed the empires of world-historical importance. The kin groups combined into great political entities and in the process of expansion their pattern of differentiation into social classes was evolved. Thus political and kinship structures are historically interrelated.

The common genesis, subsistence base and social organization of nomadic pastoralism, the common polity and the development of historical processes make the steppe Turks and Mongols into a cultural unity. The geographic features of aridity and interior drainage have made their impress on the cultures of the region. The aridity limited the areas of agriculture; the lack of waterways caused the development of overland trade routes between the Mediterranean and the far east.

Tibet is a specialized subarea in interior Asia. The main features of the region extend into the Tibetan highland; nomadic

pastoralism is as important as agriculture. The herds are composed of sheep, goats, yaks, cattle and horses. There is no intensive agriculture; farming is poorly developed, although sedentary. Tibet is the avenue whereby Buddhism was introduced into interior Asia. In southern Tibet, near the Indian border, animism is dominant. Elsewhere, in addition to the native Lamaism (mo-

FROM NORTON GINSBURG (ED.), "THE PATTERN OF ASIA," ENGLEWOOD CLIFFS: PRENTICE-HALL, INC. © 1958

FIG. 5.—MAJOR LANGUAGE GROUPS OF ASIA

nastic Buddhism), is found the Bon faith, a form of shamanism. Tibet is a theocracy in which the chief of state is believed to be a reincarnation of the Buddha and is the chief of the religion. The nomads of Tibet are patrilineally organized. A feature of Tibetan marital practices is a form of polyandry, the marriage of a woman to two or more brothers.

East Asia.—East Asia is an agricultural region: the Chinese have the largest number of peasants in the world. The densities of population in parts of China, such as the coast near the mouth of the Yangtze river, are among the highest in the world. Intensive exploitation of the soil is a necessity for the immense population, which occupies an area not much larger than continental United States. Agriculture is based on a complex organization of water resources by dams, dikes, ditches, canals, reservoirs for flood control, irrigation and conservation. Land falling under the water-conservation effort was about one-fifth of the cultivated area in traditional China. In the late 1950s it was nearly half the cultivated area. Political control in China rested on water control by the rulers.

China is relatively homogeneous in population; the Chinese spread over their present territory in historic times by their march to the tropics. In consequence, China is 94% Chinese. There is considerable linguistic and cultural diversity but at the same time solidarity through sharing of the symbolic value of Han nationality.

Rice cultivation dominates in the south and wheat in the north; the Yangtze valley is a transitional zone. The sweet potato has gained increasing importance in the south, where conditions for cultivation are favourable. The Chinese parts of interior Asia—Mongolia, northern Kansu, Tsinghai, Sinkiang and Tibet—have agriculture mainly in oases and protected valleys. In China proper there is little pastoralism. Whereas in Outer Mongolia there are about 30 head of stock per person, in China there is only one head of stock for every two or three persons. Animals bred for work and used only secondarily for food include the water buffalo in the south; the donkey, horse and mule in the north; the ox in the north and south. The pig is raised for food, hides and bristles; sheep and goats are raised for meat, hides and wool.

China, aside from the peoples of interior Asia and Manchuria, has a number of less numerous peoples scattered through the country. Some of them have been displaced and some absorbed in the course of the Chinese movement southward. These peoples are part of the Sino-Tibetan-Burman-Thai stock. The most important are Thai-speaking peoples in southwest China, chief among these the Chuang of Kwangsi, the largest non-Han nationality of China, numbering about 7,000,000. They are rice farmers, like the Thai peoples in southeast Asia. Also inhabiting the mountainous region of southwest China are the Puyi, Nung, Sha, Sishuang and Tehung; these are less numerous Thai peoples related to the Chuang. More distant linguistic and cultural relatives are the T'ung, Shui and Maonan of south China, and the Li peoples of the mainland and Hainan Island. The Yi and Kachin of Burma and adjacent China and the mountain-dwelling Miao and Yao peoples of central China are members of the same speech stock. (*See* also THAI PEOPLES.)

Typical are the Payi of the Tibetan-Burman group, in the valleys of the upper Mekong and the Salween in the Burmese-Yünnan border area. They live by rice agriculture and stock raising; the buffalo is used as a draft animal. They share traits with the Burmese in following the Hinayana or Lesser Vehicle (southern) branch of Buddhism; on the other hand, they are strongly acculturated to Chinese ways; *e.g.*, in burial customs. The Tibetan-Burman-Thai groups are an earlier population whose areas have been considerably restricted by Chinese southward movement.

Japan shares a number of traits with China, including a high rural population density, the careful management of resources and the terrace-rice agricultural system found throughout Japan and in parts of China (*e.g.*, the Szechwan basin). The intensive exploitation of the land means low development of stock breeding. Horses and cattle are few, and are used as work animals. Hogs are of greater importance for food, as in China. Other than the grains, the chief source of food comes from the sea, and a number of fishing techniques of wide Pacific distribution are found in Japan, such as employment of the harpoon, the fish spear (used through the ice) and various fishhooks. Japan shares with China the use of birds in fishing. A number of features of social organization and religion also bring China and Japan together.

The Japanese have a relatively homogeneous culture, combining traits of indigenous, Chinese and Pacific-wide distribution. The population and culture of Japan are virtually all Japanese. In the extreme north of Japan, and on Sakhalin and the Kuriles, are a small number of Ainu (*q.v.*), a non-Japanese people who are not placed with certainty with respect to linguistic, cultural or physical type. They are probably responsible for introducing a number of arctic traits into Japanese culture; they are possibly related to the Gilyaks and to the Japanese linguistically.

The neighbours of the Japanese to the south are the Ryukyu islanders. The Ryukyuans are related to the Japanese in language; they appear to have preserved a number of archaic Japanese features and have adopted the Japanese script and Buddhism. The culture of the islands reflects certain southerly connections of the archipelago generally, in the preparation of wine for religious ceremonies by chewing rice kernels, in tattooing and in the construction of houses on piles.

Korea is the third main member of the far eastern culture area. Much of the material culture, such as house forms and settlement patterns, are of Chinese derivation; moreover, Korea has been the avenue of transit of a number of traits from China to Japan, among them stock breeding, musical instruments, large portions of the vocabulary and certain aspects of Buddhism. The Chinese system of writing has been reworked both by Koreans and Japanese to transcribe their own languages. The three languages are genetically independent. Outside their native country Koreans have settled in neighbouring parts of Manchuria; there is also a large Korean colony in Japan.

Korean civilization, which covers two millenniums, is a combination of indigenous traits and long-term Chinese influence. Until the early 20th century Koreans maintained such forest traits as tiger hunting with the use of imitative calls, spears, lances and trained dogs.

Manchuria is the homeland of the Manchus of the Tungusic family of the Altaic stock. They have strong north Asian connections. The Manchus formed the last conquest dynasty of China, 1644–1912, in the course of which most of them became thoroughly sinified. Only a few remnant groups scattered in Manchuria and a few colonies in Sinkiang kept apart from the process of absorption by Chinese culture.

Manchuria has been the arena of a combination of steppe and northern forest elements. The Manchus, of northern origin adapted the Mongol script and politico-military organization which they put to their own use in the conquest of China. Chinese culture traits were early introduced into the area. Manchuria has been settled during the 19th and 20th centuries by Chinese farmers, a movement comprising one of the greatest mass migrations in history.

There are a number of common features of social organization in east Asia. Kinship is generally reckoned in the paternal line among the Chinese, Japanese and Koreans. A system of patrilineal clans identified by name forms the basis of the traditional society. The veneration of eminent ancestors is found through the area, and is the focus of a number of cult practices: ceremonial offerings, prayers, sacrifices. In China and Korea there is a strong tradition of exogamy on the basis of family names. By tradition the typical, extended family is composed of several generations of kin; married sons remain with the parents together with their families, provided the family lands can support them.

The religious picture is exceedingly complex. Ancestor worship has been mentioned, together with family and clan temples and cults. In addition, shamanism is widespread. Taoism (*q.v.*) has a long history in China and Korea; Confucianism (*q.v.*) has had a great influence both in China and in neighbouring countries. Buddhism, introduced into China from India during the T'ang dynasty, has been long and deeply rooted in Korea and Japan. The dominant form is northern Buddhism, the Mahayana or

Greater Vehicle. However, there are Hinayana areas in south China. The cult of the emperor and the state traditionally was given a focus in the religions of the area: Confucianism (to the extent that it is a religion) in China and Korea; Shintoism in Japan.

The Indian Subcontinent.—This region is predominantly agricultural; certain areas, such as the delta areas of East and West Bengal (East Pakistan and India), achieve densities of population no lower than the Yangtze valley. These are regions of intensive rice and fibre plant (cotton, jute, hemp) cultivation; irrigation and water technology generally are well developed. Much of the northwest of the subcontinent is desert. The summer monsoon brings needed rainfall, failing which India is subject to drought and famine. The great mountain ranges of the north form a natural limit correlative with that of the Indian cultural pattern.

Within the broad frame of cultural and natural unity of the region there is vast diversity which was emphasized by the partition of the subcontinent in 1947 into the two states, Hindu India and Muslim Pakistan. The cultural divisions within Hindu India are complicated by the caste system (*see* CASTE [INDIAN]).

The present population of the Indian subcontinent has been formed out of the union of Indo-Aryan invaders of the 2nd millennium B.C. with the indigenous peoples: Dravidian, Munda or Kol, Sino-Tibetans and a number of smaller groups. The population of India is second in size only to that of China; the rural population predominates over the urban in a ratio of 5 to 1, only slightly less than in China. The degree of urbanization of Pakistan is about on the level of China.

The ethnic diversity of India is far greater than that of any of the far eastern countries. In India after the partition there remained four chief linguistic-cultural constituents: Indo-Aryan, Dravidian, Munda and Sino-Tibetan (*see* INDIAN LANGUAGES).

1. Indo-Aryan. These peoples, who appeared for the first time in India during the middle of the 2nd millennium B.C., are settled chiefly in north India. They are divided into a number of subgroups on the basis of provincial, linguistic and caste differentiation. The principal linguistic divisions are west Hindi, centred near Delhi, and Urdu (a dialect of west Hindi with numerous Persian, Arabic and Turkic loan words); east Hindi, with its four chief dialects, Bihari (in Bihar), Oriya (Orissa), Bengali (East and West Bengal) and the Hindi dialect of Assam. In the west, Gujarati, Rajputani, Sindhi and Punjabi are the main languages of the Indo-Aryan family.

Together with the neighbouring Iranians, the Indo-Aryans form the Indo-Iranian grouping of the Indo-European linguistic stock. The Baluchis, who live partly in Iranian and partly in Pakistani Baluchistan, belong to the Iranian group. The Kafirs, who live partly in Afghanistan and partly in Pakistan, belong to a group of their own, which, according to the Norwegian linguist G. Morgenstierne, branched off from Indo-Iranian at a time when both language groups were closer together than they are today; the Kafir and closely related Dardic languages, including Kashmiri, and the dialects of the Northwest Frontier (Chitral), Gilgit, etc., are closer to the Indic than to the Iranian language family. The Gypsy language belongs to the Kafir-Dardic-Northwest linguistic group. The entire group numbers from 200,000,000 to 250,000,000 speakers.

2. Dravidian. The speakers of this language family are primarily in south and central India and on northern Ceylon. Tamil, Telugu, Malayalam and Kanarese (Kannada) are the chief Dravidian languages of southern India; Tamil is dominant in northern Ceylon. Related to Kanarese are Tulu, Kodagu and the languages of the Toda and Kota tribes. Dravidian languages of central India are Marathi, Gond, Kui, Oraon, Malto and Kolam. These once occupied a larger region than they do today through the expansion of the Indo-Aryan languages. Far to the northwest, in Baluchistan, are found the Brahui, Dravidian speakers who suggest a once far wider distribution of the Dravidian tongues. There are one-third to one-fourth as many Dravidian as Indo-Aryan speakers.

3. Munda or Kol. Their main distribution is in Bihar (the Chota Nagpur district), Madras and Madhya Pradesh. Their linguistic affinities lie to the east, with the Mon-Khmer peoples, forming the Austro-Asiatic linguistic stock. The agricultural Santal are the largest group of the Munda family; to this family belong the Karmali, a caste of ironworkers; the Mundari proper and a number of others: Birhar, Koda, Kurku, Kharia, Patua, Ho, Sabara and Gadaba. The Nicobar islanders are Austro-Asiatic (their exact placement is still under debate); the Khasi of Assam are of the Mon-Khmer language family of the Austro-Asiatic stock.

Some of these peoples have introduced a Negroid element into the physical types of India. A number of them, like the Birhar, are forest dwellers; others have special occupations, like the Karmali, noted above, and the Koda, who are road workers. They are *in toto* far less numerous than the Dravidian peoples.

4. Sino-Tibetan. In the Himalayan districts of India and in neighbouring Bhutan the great majority of the people are Sino-Tibetan speakers. North and east of Kashmir are the peoples of Baltistan, Ladakh and Lahul who are related to the Tibetans in language; in Baltistan or Little Tibet are islamized Tibetans, the only ones so converted. The population of Nepal is Tibetan speaking. Also in the Sino-Tibetan family are the Lepcha of Sikkim and the Bhutani, Bhotia and Lhopa.

In the western Himalaya region are found smaller groups which are unrelated to their neighbours, such as Burushaski; R. Bleichsteiner has suggested that their morphology is reminiscent of languages of the northeast Caucasus. In Assam are a number of peoples who live by hunting and slash-and-burn agriculture. These were related by B. S. Guha and, following him, S. K. Chatterji to a Negrito folk once widespread in India. Negritos (*q.v.*) were found in the Andaman Islands; they have left traces of their physical type in Cochin and Travancore (south India) and in eastern Bihar (northeast India). For the most part they have been absorbed by later arrivals.

The traditional Indian extended family was undergoing change in the 20th century, being in part replaced by a family with only one conjugal pair. The Indian rural scene through most of the country is built around villages which are nucleated or grouped and led by headmen. However, in Travancore-Cochin and west Madras, houses tend to be dispersed rather than grouped. The nonnucleated village has a wide, if sporadic, distribution in north Persia and in both east and west Turkistan. There, agricultural populations, often numbering several thousands, may aggregate in formless masses with no perceivable pattern or clustering. Nonnucleated villages are governed at the district rather than the village level.

Marriage in Hindu India follows caste endogamy; an important variant is the practice of hypergamy, the "upward" marriage of women. The patriline is the standard mode of descent; however, the Dravidian Nayar of Malabar and the Vedda of Ceylon are well-known matrilineal groups. The Toda have double descent and practise polyandry. Matrilineal organization is widespread in south India among the non-Indo-Aryans; *i.e.*, the Dravidian and Munda peoples. Likewise the christianized Khasi of Assam have a strongly matrilineal organization. Inheritance among these peoples follows in the maternal line and residence is matrilocal. On the other hand, the Dravidian Baiga, Bhuiya, Coorg, Gond and Reddi were classified as patrilineal and patrilocal by G. P. Murdock.

The religious systems of India are complex (*see* HINDUISM). Variation of the dominant Hinduist creeds is multiplied by caste cults. Islam is the official religion of Pakistan; there the Sunni doctrine predominates, but there are also Shi'ite and Ismailian peoples. Buddhism, which had its historical foundation in India, spread far beyond to other Asian countries, but has only a small number of members in India proper. Jainism is an early independent offshoot of Hinduism. The Parsis are Zoroastrians and dualists in belief. The Sikhs have their own monotheistic religion, which was a 15th-century Indic response to the Islamic incursion in the Punjab. There are small Jewish and Christian colonies of great antiquity in the south of India.

Ceylon is closely related to the Indic cultural area. The chief

population is Sinhalese, an Indo-Aryan people. The Tamils have settled in the north of Ceylon, reversing the age-old pattern of movement, since it is the Indo-Aryan which gave way. The Sinhalese of Ceylon are Hinayana Buddhist. However, Sinhalese also form the chief population of the Maldive Islands, where they are Muslims. The Laccadive Islands, off the west coast of India, are inhabited by Malayalam-speaking Muslims.

Southeast Asia.—This is an area which exhibits indigenous features, but which has also been subject to long-term and profound acculturation with India and China. It is the least clarified of the main cultural areas of Asia. There are three main linguistic stocks: Mon-Khmer, Sino-Burman-Thai and Malayo-Polynesian. The Mon-Khmer languages include Mon, Cambodian, Kha, Moi, Wa, Khasi and Garo; the Sino-Burman-Thai languages include Thai or Siamese, Laotian (Lao), Miao, Yao, Li, Yi, Kachin and Chuang; Malayo-Polynesian includes Malayan and Moi (as distinct from Mon-Khmer Moi). There are also isolated languages, whose presence may antedate the distribution of the larger stocks on the peninsula. These are spoken by small, relatively primitive groups who inhabit the forests and live by hunting and gathering plants: Yumbri of the Thailand-Laos border area; Senoi and Semang of Malaya; "Sea Gypsies"—Orang Laut and Bajau of Malaya and Indonesia, and Salon (Selong) and Mawken of Burma. Semang is a collective designation for a group of Negrito tribes of Malaya. The Negrito peoples are a distinctive type, small in stature, with a relatively homogeneous culture. They are widely distributed in the Philippines, the Molucca Islands, the Andaman group, and on the mainland in Malaya and Thailand. It is evident that the Negrito, both as a physical type and as a culture, once had a wider distribution than today. Their economy, social organization and technology are simple.

The Sea Gypsies are not a homogeneous cultural group. The Mawken have two divisions, one in close symbiosis with Malayans and Chinese of the region, the other in isolation. They live by the products of the sea. H. A. Bernatzik described their fishing as of simple technology. They have neither nets nor stakes, but fish with the spear and harpoon. The people live on boats, in extended families; a group of boats forms a community. Shamanism is reported among them.

The agricultural peoples are of two kinds: those with highly developed, intensive agriculture, with irrigation, fertilizer and the plow; and those with hoe or digging-stick agriculture. Rice is the main crop of both the advanced and the simple technologies. The simpler agriculture, lacking irrigation or fertilizer and usually carried on in poor, upland soil, is impermanent. Fields are frequently abandoned for long periods by the Miao, Yao and some Karen and Kachin. Those Karen and Kachin who live in the valleys use the plow. All the simpler agricultural peoples do some hunting, gathering and fishing.

The Burmese, Thai, Malay, Cambodian, Laotian and Vietnamese peoples have a high cultural development. They share a complex combination of indigenous traits with a heavy overlay of Chinese and Indic influences. The Malays, a large proportion of Indonesians and a small part of the population of the Philippines are Muslims. In addition to profound influences on the material and spiritual culture of southeast Asia, India and China have both contributed large numbers of migrants in recent centuries who form a major part of the commercial urban as well as some of the rural populations of the area.

City life and commerce, state organization, agricultural technology (irrigation, the plow, the cart, sericulture) are related to India and China. Taoism, Confucianism, Buddhism are omnipresent among the shamanist and Muslim peoples; Christianity has spread among the Karen.

Southwest Asia.—This region is remarkably homogeneous in its geographic features and in the dominant religion of the area, Islam. The Islamic religion is divided into two main branches, the Shi'ite, centred in Iran, and the Sunni, centred in Arabia. A third branch, Khawarij, in eastern Arabia, has little numerical importance. While Islam is the dominant religion in southwest Asia, there is a large Jewish population in Israel and there are significant Christian communities in Lebanon and Turkey.

There are three chief ethnic and linguistic components of southwest Asia: Semitic, Iranian and Turkic. The Semitic peoples are primarily the Arabs. Arabic is divided into a number of dialects in southwest Asia, the chief of which are those of the Arabian peninsula, Syria and Lebanon, and Iraq (*see* ARABIC LANGUAGE). Small groups of Arabs, both farmers and nomads, also live in southwest, central and eastern Iran. Arabic, both classical and modern, belongs to the southern branch of the Semitic family. There are scattered groups of Syriacs or Aysors in Syria, northwestern Iran and northern Iraq. Syriac is related to Aramaic of the northern branch; Hebrew is classified in the western branch of the Semitic stock (*see* HEBREW LANGUAGE). These tongues are not mutually understandable; however, there is a tendency toward uniformity among the Arabic dialects. (*See* also SEMITIC LANGUAGES.)

The Iranian speakers in the area are divided into two chief groups: west Iranian or Persian and related tongues; and east Iranian or Pashto (Pushtu), the official language of Afghanistan, and related tongues (*see* IRANIAN LANGUAGES). Persian, or Farsi, is the common and official tongue of Iran; its close linguistic relatives are Lur, Bakhtiari, Kurdish and Baluchi. Various dialects of Persian are spoken in Soviet Tajikistan, Afghanistan and in parts of Iraq. The Lur and Bakhtiari are mountain peoples of western Iran who speak a distinct language closely related to Farsi. The Kurds inhabit parts of eastern Turkey, northern Iraq and northwestern Iran. The Yezidi live in Kurdistan and speak Kurdish but have a religion which combines Muslim and Christian with other elements.

The Lur and Bakhtiari are partly agricultural and partly pastoral. They have developed agriculture significantly only during the 20th century, largely because of economic and political pressure from without. The Baluchi of southeastern Iran and neighbouring parts of Afghanistan and Pakistan are primarily herdsmen; Persian farmers live among them.

Gilak, spoken in northwest Iran, is related to Farsi. The Gilak are a mountain people with well-developed agriculture and practise some stock raising.

Talysh is an Iranian tongue, related to Kurdish and spoken in the Caucasus mountain districts of the Soviet Union and in the Caspian district of Iran.

Eastern Iranian languages related to Pashto include those grouped under the name Mountain Tajik or Galcha. These languages are spoken in the Pamirs by highly isolated communities, many of them of the Ismailian sect of the Shi'ites.

Pashto is the language of the Pathan of Afghanistan. The Pathans have a mixed agricultural and pastoral economy, like the Lur and Bakhtiari. Tajik (west Iranian)-speaking farmers live among them. The Mountain Tajik (east Iranian) also have a mixed economy. Irrigation is a necessity for agriculture throughout the region.

The Kafirs are an indigenous population of the Hindu Kush mountains, whose language has affinities to Indic and to Iranian. They were a mountain folk, converted to Islam in the latter part of the 19th century. Their pre-Islamic religion, still practised in distant and inaccessible parts of their country, is a dualist one: a good deity, Imra, is counterposed to an evil deity, Yush. Their closest linguistic kin is the Dardic group of languages.

The third major population in southwest Asia is composed of the Turks, most of whom have moved in during the last 1,000 years (*see* TURKIC PEOPLES). Those of Turkey are the largest numerically in this group. The Anatolian Turks are almost entirely given over to farming or to urban life; pastoralism is practised only by a few groups of Turks in the southeast. For the most part stock breeding is carried on by communities whose basic subsistence is agriculture. Azerbaijani Turks live in northwest Iran and in the contiguous Soviet Azerbaijan. They are an agricultural people, with secondary support from stock raising. The Turkmen of northeast Iran and north Iraq, originally a pastoral nomadic group, became largely agricultural and in part urbanized. The Gashgais of southwestern Iran are primarily pastoral nomads; a small proportion in western Iran are sedentary farmers. Uzbek farmers live in Afghan Turkistan, that is, the

low steppe-desert region near the Soviet frontier.

The Hezara of Afghanistan are a problem apart. By origin Mongols and nomadic pastoralists, they have become Persian-speaking farmers and urban dwellers. Only small groups in northern Afghanistan still retain the Mongol speech, which is heavily iranized. The Hezara are to this extent similar to the Manchus; in the process of conquest both took over the tongue of the conquered people and the local culture generally, save for tiny isolated enclaves.

Aside from these principal ethnic and linguistic groupings, there are a number of smaller groups. Armenians are Christians living in the Armenian S.S.R. and in nearby regions of Turkey. They are outstanding traders and comprise a considerable urban element throughout the area. Jews, aside from those resident in Israel, live in the cities of the middle east and have a role comparable to that of the Armenians in commerce.

The traditional family organization of southwest Asia is predominantly of extended type, patrilineal and patriarchal throughout the area. However, as urbanism develops, and as traditional folkways give way to modern, the family is changing in form to a nuclear or conjugal type in the cities and urban fringe. Nomadic groups such as the Arab Bedouin and Baseri, the Turkic Gashgai and Iranian Baluchi have retained a traditional family and social organization. The peoples with a mixed economy—Bakhtiari, Lur, Turkmen, Kurd, Kafir—have experienced a transformation in social organization. The Arabs of the oil territories in Kuwait, Bahrein and Saudi Arabia and the Persians and Arabs of Iranian Khuzistan have been transformed to an even greater degree. The continuation of traditional society may be found in enclaves such as Baluchistan that remain apart by reason of geographic inaccessibility or lack of significant raw materials.

Cultural Focuses.—The cultures of eastern and northern Asia are focused in China, in which the highest cultural development in the area was attained. Proceeding north from China, the cultural units become steadily smaller and the number of communities in a culture and population density decrease. To the north of the Chinese are the Mongol nomadic herders; to the west are the Turkic.

There is little difference between the steppe nomads and the sedentary Chinese in complexity of social organization; each culture area has a complex social stratification and proliferous specializations—economic, political, religious. The difference between the two groups appears to lie in the durability of institutions employing the various specialists. The Chinese and the nomads have many elements in common but the former have had metallurgy, writing paper, textiles, urbanism for a longer time and continuously.

The forest area contains still simpler peoples, measured by these criteria. The populations are smaller, and their densities significantly lower than those of the Turks and Mongols of the steppes. The largest indigenous population, the Yakuts, are historically recent in the area.

The forest economy is simpler than that on the steppe. Instead of raising variegated stock, forest dwellers have but one domestic herd animal, the reindeer. The Yakut have had horses and cattle but their stock are fewer both in absolute numbers and per capita. Moreover, their social institutions are simpler. Nowhere are there permanent social stratifications. However, the Tungusic and Samoyedic peoples live in kin villages which in turn have broader relationships traced in the paternal line. They are without writing of their own and have few specialized occupations other than that of shaman.

The tundra peoples are simpler yet. Their population sizes and densities are small, at the lower limit of the population sizes and densities of the taiga folk. They move in small bands which do not trace kinship with other groups and live mainly by fishing and hunting, which are supplementary sources of subsistence for the taiga and steppe peoples.

The cultural topography of eastern and northern Asia may be represented by a downward gradient from south to north. Westward from China is the arid zone of Turko-Mongol pastoral nomadism with enclaves of oasis farming. There are pockets of primitive hunters in the vicinity of the mountain lakes of Tsinghai and Sinkiang. South from China is an area of long and profound Chinese influence combined with indigenous and Indic traits.

Indic culture has achieved as dominant a position in south Asia as Chinese culture in east Asia.

There are two continent-wide networks of religious institutions. Southwest Asia has been the centre from which Islam spread to Pakistan, Turkistan, China, Indonesia, Malaya and the Philippines. Thus there is a great network of religious practice and doctrine in central, east and southeast Asia, whose historical and ideological focus lies in southwest Asia.

A religious institutional network has also spread from India. Ceylon, Burma, Thailand and parts of the Indochinese peninsula belong to the southern Buddhist tradition; Tibet, Mongolia and, to a considerable extent, China, Japan and Korea belong to one or another branch of northern Buddhism.

Aside from these, Taoist and Confucian influences may be perceived in the countries of Indochina. Christianity has had a sporadic but ancient distribution in Asia. The culture areas of Asia have been brought into various unifying combinations by the spread of religious institutions.

At different times in the history of Asia there have arisen a number of political enterprises which have brought together different cultural worlds in various combinations, such as the Chinese, Indian and Persian empires.

The Mongols and Turks have, during the past 2,000 years, created empires that temporarily combined all or parts of the steppe with all or parts of China, India and southwest Asia. The political and military framework within which the empires were formed was at the same time an economic framework. The movement of agricultural products from China to the steppe and of pastoral products from the steppe to China has been accomplished by trade, conquest, raiding and tribute collection. The economic interchange has formed a great institutional net, bringing together interior Asia and China and, to a lesser extent, south and southwest Asia.

Trade moved across Asia between Byzantium, Persia and Syria on the one side and China on the other along the "silk road" in ancient and medieval times. The Chinese have also traded with north Asia. Han artifacts have been excavated in Yakutia. India has had a long tradition of trade with southeast Asia. Economic, religious and political movements have spread from India to Burma, Thailand and Indochina, where a number of states have been formed with characteristic Indic institutions; these are the hinduized states of Indochina.

Agriculture is intensive—plow cultivation with fertilization and irrigation—in the high cultures of Asia. More primitive agriculture is practised in the uplands of southeast Asia and in adjacent parts of India and China. There the digging stick replaces the plow; fertilization and irrigation are little known and agricultural sites are changed in a steady round.

Nomads may be differentiated by their characteristic tents or house types. The nomads of southwest Asia live in black cloth tents. Altaic nomads of interior Asia live in felt tents on a lattice frame. The reindeer herdsmen to the north live in tents of larch, birch or other bark, or hides and skins, in wooden huts or semi-subterranean earth and wood houses.

Most hunting, fishing and food-gathering peoples of southeast Asia and Siberia traditionally live in isolated, relatively self-sufficient communities. Even groups bearing the same name, such as the Chukchi, divided as they are into hunting and herding branches, have little interdependence. Specialization and interdependence between herders and farmers throughout the rest of Asia is more highly developed.

For related material on the peoples of Asia, consult articles on individual countries (CAMBODIA; TIBET), regions (ASIA MINOR; LAPLAND), tribal and ethnic groups (MALAY; PATHAN), languages (FINNO-UGRIC LANGUAGES; THAI LANGUAGE) and religions (ARMENIAN CHURCH; TIBETAN BUDDHISM).

B. Physical Anthropology

It is convenient to consider physical anthropology (1) from the standpoint of paleoanthropology, which concerns itself with the study of the fossil remains of man and his nearest relatives in the animal kingdom; and (2) from that of anthropography, which deals primarily with measurements and other records of contemporary human populations. The evidence of paleoanthropology and anthropography may throw much light on the origins, migrations and histories of the physical types represented in a given area.

Fossil Man and Other Primates.—The Asian continent was undoubtedly the scene of a large-scale dispersal of early members of the natural order to which man belongs, the Primates; yet a supposed corollary of this event or series of events, that he also emerged there, has been generally abandoned in favour of his probable origin in Africa—a return to Charles Darwin's views of the 19th century. Nevertheless, Asia is the home of the only surviving genus (*Tarsius*) of the tarsiers, small nocturnal primates (about the size of a newborn kitten) nowadays confined to Borneo, Celebes and the Philippines, the fossil remains of which are of great importance in the study of man's remote ancestry.

Several tarsierlike creatures existed during the Paleocene and Eocene periods of the Tertiary epoch in North America and during the Eocene in Europe. A widely held opinion is that one of these gave rise to the catarrhine primates, namely, the old world monkeys, the tailless or anthropomorphous apes and man. Fragments of jaws and teeth of Upper Eocene age from Burma have been given the generic names *Pondaungia* and *Amphipithecus*, while the forms they represent are thought by some students of primate phylogeny to mark a stage in the transition of primitive tarsioids to catarrhines. The U.S. paleontologist George Gaylord Simpson considered them to be possible apes of uncertain affinities.

The extinct great apes belonging to the genera *Dryopithecus* (also European), *Sugrivapithecus* and *Bramapithecus*, whose remains have been recovered from Pliocene horizons in the Siwalik foothills of the Himalayas, are clearly too specialized to be accepted any longer as man's potential ancestors; but claims that the Lower Pliocene *Sivapithecus* (to which the Upper Pliocene *Ramapithecus* may be allied) of western Pakistan, Kashmir and northern India could be placed in the direct line of human descent were made by Guy E. Pilgrim in 1915 and 1927. In 1953 L. S. B. Leakey suggested that an African species of *Sivapithecus* from the Lower Miocene beds of Kenya might be a true representative of the stock from which man arose. Some enigmatic primate molars of enormous size sold in 1935 and 1939 as "dragon teeth" by Chinese pharmacists in Hong Kong and Canton to G. H. R. von Koenigswald, who proposed the genus *Gigantopithecus* to receive them, cannot be definitely assigned either to a great ape or to any member of the human family, the Hominidae. (Indirect evidence points to their having come from Middle Pleistocene deposits in Kwangtung and Kwangsi in southern China.)

There are no misgivings about the Lower and Middle Pleistocene remains (called *Pithecanthropus* or Java man) discovered at various sites in Java over the half century 1890–1941, or about those of Peking man or *Sinanthropus*, of Middle Pleistocene date, found at Chou-k'ou-tien near Peking during the 1920s and 1930s. Their owners were not only certain hominids but should, by the ordinary canons of zoological classification, be included generically in *Homo* (*see* Man, Evolution of).

Java man and Peking man (the best inclusive terms to use at the moment) stood upright and had low flat skulls of about 1,000-c.c. capacity in adult males—the average for present-day European men is 500 c.c. higher—with the greatest breadth as far down as the level of the ear openings, continuous bony bars above the orbits and across the occiput, a constricted frontotemporal region and mandibles lacking any chin projection. No artifacts can be directly associated with Java man, but Peking man made tools from stone and bone and knew the use of fire. Java man is represented by the parts of half a dozen craniums. Peking man was represented by more than twice as many, but the whole of the Chou-k'ou-tien material disappeared at the time of Japan's entry into World War II. The rest of the fossil hominids from Asia not of the species *Homo sapiens* are Upper Pleistocene in date.

Eleven or twelve fragmentary calvariae or brain cases, found with two shinbones at Ngandong on the Solo river in central Java in 1931 and 1933, constitute Solo man or, according to the original description, *Homo* (*Javanthropus*) *soloensis*. In appearance they resemble the skulls of Java and Peking man but have rather larger capacities. The human remains excavated in caves near Taghba on the Sea of Galilee in 1925, in the Mt. Carmel range near Atlit (Athlit) between 1929 and 1934 and in the Jebel Kafzeh near Nazareth during 1933 and 1934 belong to Neanderthal man. F. Clark Howell in the U.S. held that *Homo sapiens* evolved from Mt. Carmel and similar groups. This thesis was opposed by Henri V. Vallois in France, Gisela Asmus in Germany and others, who would seek our ancestry in a more generalized human form. The skeleton of a child aged about nine, discovered in the Teshik-Tash cave near Samarkand, Uzbekistan, in 1938 marks the eastern limit of Neanderthal man's distribution.

Distribution of Physical Types.—The single existing species of mankind, *Homo sapiens*, is polytypic and may be divided into four or five major racial groups or varieties, each composed of a number of races or subvarieties. Certain physical features tend to be constant within a particular major group and the average values of others distinguish its constituent races. These are the familiar anthropometric and anthroposcopic characters and to them may be added the discriminating powers of the various blood-group systems. Relative to the vast size of Asian populations, the data on their blood groups, apart from those of Japan and Indonesia, are meagre. Of the ABO and MNS systems, the high frequencies of the B gene, especially in Pakistan, northern India and central Asia, are probably adaptive, as are those of the M gene in southern Asia. A is often less abundant than B, and O loses its otherwise almost universal predominance. Eastern Asia, like Europe, has only a slight excess of M over N; and S, rare in China, is common in India Of the respective Rhesus and Duffy systems, CDe (R_1) becomes increasingly predominant from west to east, and Fy^a has a very high frequency.

Of the Mongoloid, Caucasoid, Australoid, Negroid and Khoisan major groups, all but the last, which includes the Bushmen, Hottentots and Sandawe of Africa, have Asian representatives. The majority of the inhabitants of Asia, however, are Mongoloids, who occupy most of the northern, central and eastern parts of the continent with outliers in Europe (Kalmucks and Samoyeds), Oceania (Micronesians and Polynesians) and the new world (Eskimos and American Indians). The Mongoloid races in Asia are the Mongolian, divided into Aralian, Tungusian, Sinian and Pareoean subraces; the Himalayan, with two main branches; and the Indonesian. The European or Caucasoid peoples in Asia from west to east and north to south are the Uralic (Voguls and Ostyaks) between the Urals and the Ob basin; the Ainu (*q.v.*), in Sakhalin and Hokkaido, Japan, and one of the nearby Kuriles; the Pamirian, from Anatolia to Sinkiang; the Mediterranean, with one subrace, the Heberian, in the Levant and Arabia, and another, the Caspian, in Iran, Afghanistan, western Pakistan and the Indo-Gangetic plain; and the Dravidian or Chersiote of peninsular India and Ceylon.

The only Australoid type in Asia is the Veddian, whose members are sometimes known as pre-Dravidians or proto-Australoids.

It comprises the Vedda of Ceylon and the Kadir, Kurumba, Paniyan and Irula of southern and the Bhil, Gond and Chenchu of north central India. Small pockets of Veddoids have been identified in Baluchistan and in the Hadhramaut and Yemen in southern Arabia. Asian Negroid groups are wholly pygmies of Negrito race who as a rule inhabit refuge areas. They include the Andaman islanders, the Semang of the Malayan jungles and the mountain-dwelling Aeta of the Philippines. In southern India the Kadars and the Pulayas display attenuated Negritoid traits, which recur in eastern Sumatra.

If the Malay archipelago is excepted, the continent can be separated into two main anthropological regions to the north and the south of the Himalayas. The presence of the Ainu at the periphery of the first suggests that they are descended from a Caucasoid race living on the mainland, probably south of the Amur river, toward the end of the last glaciation. The Tungus, who divide the Ainu from the Uralics, are the most specialized of the Mongoloids and show the results of adaptation to extreme cold. In the second region Negritos seem to have been succeeded in turn by Australoid and Caucasoid peoples to the west and by Australoids and Mongoloids farther east. It is also possible that links exist between the Dravidians of India and the Somali of the horn of Africa.

IV. HISTORY

A. PREHISTORY AND ARCHAEOLOGY

The Near East.—After about 1930 the chief attention of near eastern archaeologists turned from the capital cities of the ancient world, like Bogazkoy (Turkey), Ur (Iraq) and Susa (Iran), to the frontier regions between early civilizations. One such district is the plain of Cilicia, in southern Turkey, where J. Garstang's excavations at Mersin and those of Hetty Goldman at Tarsus illustrated the relations between Anatolia and Syria in prehistoric times. Another is the Amuq plain by the bend of the Orontes river, where Sir Leonard Woolley's work at Atchana revealed the culture of a rich Hittite dependency, in close contact with Mesopotamia, Egypt and the Mediterranean world. Nearby, his excavations at El-Mina at the mouth of the Orontes shed much new light on the trading contacts between the Aegean and the east in the early colonizing period of the 8th century B.C. This, together with the conclusions of the joint expedition from the British School at Athens and the University of Ankara to Old Smyrna, led to a careful review of Phrygian and Urartaean evidence and a revision of former views on the origins of the oriental elements in the art and civilization of early Greece.

In Syria important work was done by Claude Schaeffer at the coastal site of Ras Shamra. This was a very cosmopolitan centre in the 2nd millennium B.C., to judge from the wide variety of languages used on its clay tablets. Some of these were inscribed in a unique alphabetic cuneiform script.

At Kultepe, the ancient Kanesh, near Kayseri (Caesarea Mazaca), T. and N. Ozguc opened the *karum* or commercial suburb of Assyrian merchants, which flourished at the time when the Hittite civilization was taking form; while at Karatepe in the Taurus mountains, the headquarters were found of a small neo-Hittite kingdom of the 8th century B.C., among whose relics was a bilingual inscription in Phoenician and Hittite hieroglyphic, which made possible great advances toward the complete deciphering of the latter enigmatic script. The mound of Beycesultan near Civril, toward the western frontier of the Hittite realm, was opened in the spring of 1954 by the British Institute of Archaeology at Ankara. In the central Anatolian plateau, a series of excavations conducted by the University of Ankara illuminated the culture of the Stone Age and Copper Age. The most important single recent discovery in this region was that of the royal graves at Alaca Huyuk, opened by the Turkish Historical society. Their rich contents proved that a high civilization throve on the plateau in pre-Hittite times, in the middle of the 3rd millennium B.C.

An expedition from the University of Cincinnati made a careful check of the stratigraphy at Hissarlik. A brief but important Anglo-Turkish deep sounding at Polatli in 1949 provided a useful continuous stratification in a district between the full excavations at Alishar and Kusura. The art of the Phrygian kingdom was illustrated by the remarkable wall paintings uncovered by the Turkish Historical society in the fortress of Pazarli, while remains of the Phrygian capital itself, at Gordium, were in part uncovered by a party from the University of Pennsylvania (Philadelphia) museum, and those of the Midas City by an expedition from the French Institute of Archaeology at Istanbul.

The British School of Archaeology in Iraq, under the direction of M. E. L. Mallowan, turned its main attentions to the Assyrian levels of the mound of Nimrud at Nineveh. Comparable Assyrian material was recovered at Sultantepe near Urfa by the expeditions of the British Institute of Archaeology at Ankara during an exploration of the monuments of Harran and the surrounding country. Throughout the fertile crescent and neighbouring regions, much attention has been given to the search for the earliest traces of settled Neolithic civilization. These were found in deep diggings at Mersin, at Jericho, at Khirokitia in Cyprus and at Hassuna and the Jarmo cave in Iraq.

In Iran, Afghanistan and Baluchistan stratified excavations are very rare. The chief are those at Siyalk in central Iran, at Hissar in the southern foothills of the Elburz and at Geoy Tepe in Azerbaijan. The main problems there concern the links between Mesopotamia and the Indus valley, and the relative chronology of the plateau and the great river valleys. Contributions to these studies were made by the explorations in Baluchistan in 1950–51 by a party from the American Museum of Natural History in New York, and by the deep sounding by J. M. Casal at Mundigak near Kandahar in Afghanistan. Apart from researches in prehistoric strata, French archaeologists in Afghanistan, who by an agreement of 1922 were given special opportunities for work in that country, explored widely for remains of the Bactrian Greek civilization; and in 1951 at Surkh-Kotal in Bactria began excavations of a 2nd-century A.D. temple with a fragmentary inscription in Greek characters.

Modern work in Arabia has included explorations of the tumulus fields of Bahrein and Hasa; several reconnaissances in Yemen, the chief of which was that from Egypt, published by Ahmed Fakhry; and extensive journeys in search of epigraphic material by G. Ryckmans.

In the Syrian desert, ordinary methods of ground exploration were supplemented by the use of aerial photography in the study of the archaeology of the eastern Roman frontier. Père A. Poidebard pioneered this work in Syria, and it was continued in Iraq and Jordan by Sir Aurel Stein in his last major journeys, of 1938–39.

In Jordan in 1947 there appeared the first of the Dead sea scrolls, manuscripts in Hebrew and Aramaic of books of the Old Testament and other works probably compiled by the Essene sect in the 1st century A.D. Later protracted searches in the caves about Khirbet Qumran produced further documents.

India and Greater India.—In India, improvement in archaeological method resulting in increased knowledge makes it possible to present an almost complete narrative from earliest times.

Stone tools of the Paleolithic period have been found distributed all over India. In the north some of these are associated with river terraces corresponding with glacial and interglacial periods. Similar aggradation and downcutting of river valleys is produced

by the dry and wet periods of the south, where tools have been found in cemented gravels and pebble or gravel conglomerate, the most complete range of tools, from Clactonian types to microliths, in one section being that at Khandivli near Bombay.

Hunting, food-gathering Mesolithic peoples, who used microliths to point and barb their arrows and as knives and scrapers, were as widespread as their Paleolithic predecessors. In forest areas this cultural stage with its use of microliths persisted to the early centuries A.D. or even later. In the valley of the Son river and the Mahadeo hills and at Singhanpur, rock paintings, physically associated with microliths, have been compared with Paleolithic paintings in Europe: actually the majority are of the early historic period and none is earlier than 1000 B.C. At Kile Gul Muhammad near Quetta a Mesolithic settlement having mud-walled huts but no pottery was found, and it is in such communities that the approach to the Neolithic, food-producing stage is observed. The Neolithic period in India is the hardest to determine, depending mainly on the advance in agriculture to make its evidence apparent. Digging-stick cultivators would show no change in material possessions from those of the Mesolithic food gatherers. Hoe cultivation, possibly with terracing, needs stone hoes and slash-and-burn cultivation needs axes. By far the greater number of ground and polished stone axes have been found in the east and south. Excavations in Brahmagiri in northern Mysore and at other sites have shown that the use of such axes persisted to the 2nd century B.C. The first settlement at the megalithic site of Burj Hama in Kashmir is of a stone-ax-using people, not necessarily connected with the megaliths.

The small amount of copper found at some stone-ax sites hardly justifies their being classed as Chalcolithic, or copper- or bronze-using, and this applies to some extent to the peasant farmers of Baluchistan. It would appear also that up to the end of the 4th century B.C. the cultural progress of greater India followed the same pattern and that a Neolithic mode of life, of which highly polished stone axes and tanged stone adzes were the highest achievement, persisted until influenced by India and China at about that time. In the hill valleys of Baluchistan, from the Iranian frontier on the southwest to the Zhob on the north, many sites have been discovered—the settlements of early peasant communities whose remains are mostly a succession of painted pottery industries. Handmade pottery, as shown by the sites of Rana Ghundai in the Zhob and Kile Gul Muhammad, was followed by wheel-thrown painted pottery of Kechi Beg-Amri type, so-called after sites near Quetta and in Sind. This is the earliest ware of this type and its makers arrived from Persia after the breakup there of the painted-pottery cultures, between 2800 and 2600 B.C. Both near Quetta, where it appears with Late Kechi Beg, and in Sind, associated with Middle Amri, is an industry known as Togau ware which is also associated in Sind with very early Nal industry types, and as these and Amri ware overlap the appearance at about 2600 B.C. of the Harappa culture pottery, a basis for approximate dating has been obtained.

Various cultures, largely represented by their pottery, fill the period between 2600 and 1800 B.C. when they were all swept away by invaders from the west. The most important of these is the Kulli culture, widespread throughout southern Baluchistan, having metallurgy as highly developed as that of the contemporary Harappa culture and a painted ware with motifs deriving both from India and Persia. Of the Nal-Nundara culture much less is known. There are definite contacts with Amri in its earlier stages, but the site of Nundara has not been excavated and the Nal cemetery seems to have been used during a period when that site was deserted, between the disappearance of a Kulli occupation and the establishment of a Zhob settlement.

In the Zhob, communities with bichrome pottery of Amri type were ultimately displaced by a people who spread from Periano Ghundai in the north and who took over on all sites southward to that of Nal, bringing their characteristic black-on-red pottery and mother-goddess figurines with them. It was this people and those of the Kulli culture who were in occupation when the period of invasions started.

In the Indus valley the peasant communities were succeeded by an urban civilization, the Harappa culture, which suddenly appears complete with all its cultural characteristics fully developed. The area affected by this culture was considerable, the two chief cities, Harappa in the Punjab and Mohenjo-Daro in Sind, being 350 mi. apart. Its outstanding features are the high level of town planning, the developed system of drainage and sanitation and the measure of civic control which these imply, unique at that remote period. The dating proposed in the mid-1950s to cover the known development of this civilization was from 2500 to 1500 B.C.

The granary at Mohenjo-Daro and the coolie lines, granaries and grain-pounding platforms at Harappa show that the economic basis was large-scale agriculture. The metallurgy of this people was well developed. The processes of raising and sinking to make deep and shallow bowls, that of lapping for joins and the cire-perdue method of casting were known, but the majority of objects were hammered from rods or cut from sheet metal. Bitumen, which was obtained locally, was used to calk the great bath at Mohenjo-Daro. Cotton clothing was worn, sometimes decorated with embroidery or appliqué cloth. Wheeled transport and a system of weights and measures completes the picture of a civilized community. A vast number of steatite seals were unearthed displaying a line of script and a picture, usually an animal, the ox, elephant, tiger and rhinoceros predominating. The undeciphered script seemed to be a syllabary of stylized pictographs produced arbitrarily as the result of a knowledge of writing. Terra-cotta figurines have been found in great numbers, the majority being oxen; male and female figures may be either deities or votaries, and clay carts and some of the animals were probably toys. Large quantities of plain mass-produced wares and fewer slipped and painted black-on-red jars represent the household pottery of the Harappans. At the two principal sites the presence of a fortified area argues for citadel rule. The culture was Chalcolithic in character, copper and bronze being supplemented by a profusion of cherty flint blades which were the normal utility knives.

After 1942 there was a great increase in knowledge about the "dark age" period, from the ending of the Harappa culture to the invasion of Alexander the Great. In the northwest, invaders, having with them an increasing Aryan element and who buried their dead en route on the Shahi tump mound in Baluch Makran, occupied small towns in Sind, their remains being called the Jhukar culture. Similar invaders also seized Harappa where their burials have been unearthed. Polychrome ceramic industries such as that of Trihni in Sind spread also over the Zhob between 1400 and 1200 B.C. In northern India the first evidence for the appearance of iron is the arrival of a people in Baluchistan from Persia, who between 800 and 450 B.C. spread from Persian Makran to the Zhob. They were horse riders who buried their dead in cairns and used iron.

Excavations at Ahichhattra (Ramnagar; 1940–44) and Hastinapur (1950–52), sites of the historic period, produced ceramic industries which stretch back to meet the early wares of the northwest. Northern black polished ware found throughout northern India dates back to 400 B.C., and stratified below this appears a painted gray ware which would start at about 650 B.C. Associated with this, but possibly originating about 200 years earlier, is an ochre-washed ware that can be linked with the copper hoards of the Ganges valley, containing swords, daggers, harpoons and axes, which previously had no archaeological context. In south India an iron-using people who buried their dead in a variety of fashions notably in megalithic tombs, succeeded, during the 6th to 2nd centuries B.C., a Neolithic people who had as their equipment ground and polished stone axes and microliths.

The Far East.—The earliest traces of human activity in Asia have been found in limestone hills at Chou-k'ou-tien, about 30 mi. S.W. of Peking. In the 1920s excavations there led to the identification of a new type of fossil man, *Sinanthropus pekinensis*, from an unusual molar tooth. Later W. C. P'ei discovered the primitive skulls, hearths and roughly chipped stone implements. Excavation at the site continued until 1939 and was later resumed by the Chinese Academy of Sciences. The crude tools are distinct in shape and method of manufacture from the hand axes characteristic of the Lower Paleolithic, but they are of comparable antiquity, perhaps about 400,000 years old (*see* MAN, EVOLUTION OF: *Pithecanthropus*). Cultures corresponding to the Middle Paleolithic of Europe, with Mousterian-type tools, had not been found farther east than the Crimea, the Chusovoy valley in the Urals and the Abkhazia district of the western Caucasus by the mid-1950s. The great expanse of Asia to the east had yielded no cultural remains between Chou-k'ou-tien and a period corresponding, at the earliest, to the later Upper Paleolithic of Europe and to the terminating millenniums of the Pleistocene or Ice Age.

Southern Siberia has been relatively well explored by archaeologists. On the Angara river near Irkutsk (Verkholenskaya gora) and in the Yenisei basin (Krasnoyarsk *kray*) are found traces of a flint- and bone-using culture somewhat resembling the Magdalenian and Solutrean of Europe, with pressure-flaked flint points and bone harpoon heads, but lacking the developed art of the west. These cultures are perhaps 10,000 or 15,000 years old. Later the stone tools of eastern Asia include many tiny parallel-sided blades with little secondary trimming, intended for mounting in series. These microliths also echo the European and north African development but lack the geometric shapes which appeared in the west. The microlithic cultures lasted long, for in Siberia, Mongolia and Manchuria they are often found combined with Neolithic elements in the shape of polished or partly polished stone axes, crude handmade pots with rounded or pointed bottoms and small triangular arrowheads. At Ulan Khada on Lake Baikal a layer containing the Neolithic additions was found stratified over another, similar but for the absence of the Neolithic types. With the advent of pottery and stone polishing, probably about 3000 B.C., these cultures are termed Neolithic, although they knew nothing of farming or cattle raising. For food they relied on hunting, assisted by a domesticated dog. Some of their pottery is decorated with the impressions of cords and notched sticks and is thereby related to a broad tradition diffused across Asia from northwest Europe to Japan and even to North America. Microlithic stone industries are known from Sjara-osso-gol in the Ordos region of northwest China, and in Manchuria at Djalai-nor and Ku-hsiang-tun. At Lin-hsi in Manchuria and Singer in Sinkiang the microliths were mingled with Neolithic elements.

The northern belt of cultures described above reaches to the sea in Kamchatka. To the south lies the cradle of the High Bronze culture of protohistoric China, based on the easy agriculture of the Yellow river valley. The Neolithic cultures which preceded the Bronze Age in this area are much more advanced than the Mongolian Neolithic and their origins seem to owe nothing to it. The southernmost zone, comprising south China, Indochina and the great islands, also possessed a distinct pre-Bronze tradition. In the Tongking province of Indochina the excavated site at Hoabinh had only small chipped stone tools unlike anything found in the north, while Bacson produced an individual kind of stone ax, polished only on the edge, and some rough pottery with impressed decoration. But in the south investigation had not gone far at mid-20th century. Over the whole of the area are found rectangular polished stone axes, sometimes like the northern ones. Their distribution overlaps but does not coincide with the distributions of quasi-cylindrical and shouldered axes. In the southern coastal provinces of China the rectangular axes are found associated on surface sites with corded pottery. The use of stone in the southern zone continued into historical times.

The painted-urn culture of Kansu, the westernmost of the three Neolithic traditions of the central zone of China, was first investigated by Andersson in its numerous cemeteries around Lan-chou. The large, handmade, necked urns accompanying the extended earth burials are richly painted with formal patterns in black, red and purple. These splendid vessels resemble those found at Anau in Turkistan and in the Tripolye culture of south Russia, but not closely enough to warrant a direct cultural affiliation. Their ancestry is mysterious; there are no linking sites in the intervening territory. Andersson went on to discover the Painted Pottery Neolithic now called after the type site at Yang-shao-ts'un in Honan province. The techniques of painting and some simple geometric decoration link the Yang-shao Neolithic (which is now known from many sites in Honan) with the Kansu culture, but there was no evidence showing their exact relation in time and space. The third Neolithic culture of central China is called Lung-shan, after the type site in Shantung province discovered by K. T. Wu. It is characterized by a fine burnished ware in wheel-turned vessels of angular outline; abundant gray pottery; rectangular polished stone axes; walls built of compressed earth; and (at the type site) by a method of divination in which heat was applied to the shoulder blades of cattle, the resulting cracks giving the augur his clues. This Black Pottery culture is traced in eastern and northern Honan, in Anhwei and as far as the Kwangtung peninsula in the northeast. Its gray ware resembles that found on numerous unexcavated sites associated with raised-earth platforms in south central China. With the Yang-shao culture it shares the vessel with three baglike feet called *li*, which is characteristic of the Neolithic of central and northeast China and is not found elsewhere.

The Bronze Age of central China is known from excavations near An-yang in northern Honan on the site of the capital of the later kings of the historical Shang or Yin dynasty. The occupation covered the period stated by the literary tradition to extend from 1402 B.C. to 1122 B.C., dates considered by some scholars to give too short a period to this dynasty, which is now thought to extend from 1523 B.C. to 1027 B.C. (For an account of the contents of this rich culture and its paramount significance for the later history and art of China, the reader is referred to the articles ARCHAEOLOGY and CHINESE SCULPTURE. Here only some points of special archaeological interest are mentioned.) The most striking material achievement of the culture is its ritual vessels of bronze reflecting aspects of a primitive religious lore. The technique is unsurpassed in the bronze art of the ancient world. Excavation

revealed hundreds of storage pits; two large building foundations of rammed earth surrounded by the graves of human sacrificial victims; burials of complete chariots and great royal shaft tombs at which human victims had been immolated by the score. Thousands of inscribed tortoise shells and scapulae used in divinations have thrown light on religious and other affairs of the Shang dynasts and furnished unexpected corroboration of the majority of royal Shang names recorded in historical texts.

The general pattern of this Bronze Age civilization is familiar from excavations in the near east, at Ur and elsewhere, but there is nothing to support the idea of transplantation of a culture from the west into central China. That the roots of the An-yang culture go deep in China itself is shown by its links with the preceding Neolithic. Yet in China no more primitive version of Bronze Age culture has been discovered.

Bronze metallurgy seems to have arrived suddenly and to have been applied to forms already evolved in other materials. The characteristic weapon, the *ko* halberd, is undoubtedly a Chinese invention. The only type owed ultimately to the west is the socketed ax, of which very few were found. Versions of the *ko* occur in the little-known Dong-son culture of southwest China and Indochina, and in the Karasuk bronze culture of the Minusinsk basin of southern Siberia. From the latter region animal-headed bronze knives of Siberian type were imported into China. The rise of the Karasuk culture coincided with the appearance in southern Siberia of a Sinid people who may have been driven from the northwest march of the Shang state by military pressure.

Japan had no share in the spread of bronze metallurgy and weapon types from the Shang centre, and was hardly acquainted with the use of metal before the beginning of the Christian era, when iron had been in use in addition to bronze for about three centuries on the mainland. The introduction into Japan of Neolithic culture, with the use of polished and chipped stone tools and pottery decorated with the impressions of cords, shells and wooden stamps, may, however, be almost as early as the appearance of the Neolithic on the mainland of east Asia. It is interesting to note that the influences discernible are from the northern and southern zones, and that no connection with the early cultures of central China is apparent.

B. EXPLORATION

Little of Asia remains hidden from the sight and knowledge of man, but for centuries the broad belt of deserts and mountains from Arabia to eastern Siberia has attracted explorers by its very inaccessibility and by the secrets it offers of past civilizations, climates and landscape evolution. Modern exploration is rarely concerned with venturing into the unknown, but rather with the scientific investigation of the little known.

Early Period.—Europe's knowledge of Asia in classical times was derived mainly from contact with traders. The salt of northern India and that of Palmyra, traded between Syrian ports and the Persian gulf, were known before Alexander's day. Silk was imported at Cos before classical times, and knowledge of its cultivation spread westward from China through central Asia and Persia. Chinese pilgrims journeyed in Turkistan from the 5th century. The advancing Mongols in the later middle ages drew attention eastward. Franciscan friars made early journeys: Joannes Carpini (*q.v.;* 1245–47) and William of Rubruquis (*q.v.;* 1253–55) in central Asia. Giovanni di Monte Corvino (*q.v.*) was created archbishop of Peking in 1307. The travels of the brothers Polo to the court of Kublai Khan and their hearsay descriptions of the farther east added greatly to contemporary information. (*See* POLO, MARCO.)

19th and 20th Centuries.—Colonial expansion engendered exploration for its own sake, and the unknown heartland began to yield its secrets to travelers and surveyors. Father Évariste Huc (*q.v.*) crossed the Ordos and Koko Nor, reaching Lhasa in 1846. Nikolai Przhevalsky (*q.v.*) crossed the Gobi and mapped the sources of the great southeast Asian rivers in 1870–73. British Indian and Russian military surveyors filled in much detail in central Asia in the last quarter of the 19th century. The names of Sir Francis Younghusband (*q.v.*) in Tibet and Sven Hedin (*q.v.*) in Persia, Turkistan, the Pamirs and Tibet stand out, the latter discovering ancient cities apparently dependent on rivers and ground water more plentiful than at present. Sir Aurel Stein (*q.v.*) continued this work into the 1940s.

Modern exploration has become increasingly scientific, though the urge to climb the world's highest peaks has been a powerful stimulus. Ellsworth Huntington (*q.v.*) in the Tien-shan and Altai (1903), the Filippi expedition in the Himalayas and Karakorum (1913–14) and later researches, *e.g.*, Hellmut de Terra in Kashmir and Tibet, have sought to unravel the climatic changes from Pleistocene times, Stein, Hedin and others contributing archaeological detail. Workers, particularly in the Tibet-Himalayan field, became numerous in the 20th century. The conquest of Everest (1953) by a team led by Sir John Hunt crowned the efforts of three decades. Among other important researches may be mentioned F. Kingdon Ward's work on the China-Burma border, F. von Richthofen (*q.v.*) in China, R. C. Andrews (*q.v.*) and later R. D. F. Schomberg in Chinese Turkistan, P. A. Kropotkin (*q.v.*) and Baron E. von Toll (19th century) and V. A. Obruchev (1926) in northeastern Russia. In southwestern Asia, archaeological excavation dominated (*e.g.*, Sir Leonard Woolley's work in Iraq), but pure exploration of southern Arabia was continued by Bertram Thomas, H. St. John Philby and W. P. Thesiger, while the geologists G. M. Lees and J. V. Harrison worked in Arabia and Persia. (B. L. C. J.)

C. SUMMARY OF GENERAL SOCIAL-ECONOMIC AND CULTURAL HISTORY

Asia is a geographical, not a historical, concept. Civilizations, great and small, have arisen in Asia in history and have interacted one on the other, but their span in both space and time has prevented the emergence of anything like an Asian culture. Turks, Indians, Chinese and so on differ in many important points, and the term Asian, Asiatic or oriental is a mere convenience. The history of Asia to be intelligible must therefore be broken down into its component parts. In the 20th century a sense of Asianism, as Asian consciousness, emerged, rather as a reaction to European and western dominance.

The Pacific ocean has limited the spread of Asian peoples to the east, but on the west the borders commonly assigned to Asia are somewhat arbitrary. The Urals mark no real division of peoples and in both the Greek and Turkish empires, for example, Asia Minor has been as much connected with Europe as with the lands to the east. However, the Urals, the eastern Mediterranean sea and the Sahara desert may roughly be taken as marking historically the western limits of Asia. It may be noted that, in a narrow sense Asia was the name of the first Roman province east of the Aegean formed in 133 B.C. By the reorganization of Diocletian this Asia was broken up into several smaller provinces, one of which, with its capital at Ephesus, retained the name of the original province.

Religions and Major Influences.—The great religions of the world—Buddhism, Christianity, Hinduism and Islam—and others of considerable importance, such as Judaism, Parsiism and Taoism, all arose in Asia. However, Christianity, though Asian in origin, has expressed itself most fully in Europe and the west, and its most important forms owe little to Asia. It has made little progress to the east of Asia Minor, and the great Christian missionary effort in southern and eastern Asia from the 16th century onward made only modest headway. Although in earliest times the Nestorians penetrated to India and China, they never had anything like the success which attended Buddhism and Islam. Yet Buddhism and Hinduism never produced much impression west of India, and Islam later was alike rejected by Christian Europe and Hindu India.

The history of Asia in the past 2,500 years is primarily the result of the interaction of five main influences: (1) Chinese; (2) Indian; (3) Islamic; (4) European; including Russian; (5

central Asian. Of these, the first four represent different kinds of civilization. The fifth has little originality but has been of significance in affecting the distribution of peoples and of political power.

China has molded the civilization of eastern Asia including Japan, Korea and Annam and has been a primary influence on Mongolia, Tibet, Thailand, Cambodia and Burma. Wherever Chinese influence exerted itself, it introduced Confucianism, a distinctive style of art and, above all, the Chinese script.

Indian influence has mainly expressed itself through Hinduism and Buddhism. These are not merely religious in nature but have carried with them Indian art and literature and often an Indian alphabet, as in Tibet, Java and Cambodia. Indian influences have affected the peoples of central Asia and of southeast Asia, including Malaysia and Indochina. Buddhism spread into China and Japan, but Indian culture on the whole has itself been little affected by Chinese art, literature or ethics.

Islam spread widely in all directions from its original home in Arabia. It subjugated the near east, in which it is still the principal religion, also eastern and northern Africa. It spread for a time into eastern Europe and Spain. In the other direction it got a firm hold in the northwest and northeast of the Indian subcontinent, and the state of Pakistan now covers these two areas. Beyond India it reached the Malay archipelago where it submerged earlier Hindu influences. Through central Asia it reached and affected China, but it gained no foothold in Japan and Indochina. Islam, like Buddhism, took with it everywhere a special style of art and culture. It was usually accompanied by the use of the Arabic alphabet and the vocabulary of this language forms a large part of the languages of the Muslim peoples.

Central Asia has been the region into and through which these various powerful influences have been projected. Archaeological excavations have shown that early in the Christian era there flourished in the Tarim basin small states, such as Khotan and Kucha, which possessed a mixed culture comprising Chinese, Indian, Iranian and even Greek elements. Buddhist, Christian and Manichaean edifices have been found as well as libraries in many languages, two of which were previously unknown. Through central Asia Greek influences and later Islam penetrated India, and Buddhism passed from India into the far east and into parts of southeast Asia.

The various tribes of the area have no common name. Linguistically they fall into several groups such as Turks, Mongols and Huns and, in the face of difficult communications and terrain, only occasionally did several of the groups come together in one state. In history, central Asia has acted rather like a sponge, absorbing pressures and sooner or later transmitting them. Time and again these pressures have produced invasions of the peripheral regions and in the Christian era the following may be mentioned: the early invasion of Europe by the Avars, Huns and Bulgarians; the conquest of north India by the White Huns; the conquest of Russia by the Mongols; the conquests of Timur; the conquest of Asia Minor and eastern Europe by the Turks; the invasion of India by the Moguls; the conquest of China first by the Mongols under Kublai and later in the 17th century by the Manchus.

The Ancient Near East.—This term is a historical concept, denoting the extent, in space and time, of the earliest civilized societies. Through archaeology, it is known that in this area the change from food gathering to food production first began and that the diffusion of agriculture, not only in the knowledge of grains but also in the technique of harvesting, took place. Toward the 3rd millennium B.C. the emergence of river-valley civilization in Mesopotamia and Egypt set this area apart from the peasant cultures of the rest of Asia and Europe. The cradle of Mesopotamian civilization was the southernmost part of the Tigris-Euphrates valley, and there the first cities arose. As is known from the remains of their pottery, the earliest settlers of this marshy plain had descended from the highlands of southwest Persia. These peoples were probably Sumerians, speaking a very remarkable language which has not been brought into relation with any known tongue. Physically they belonged to the Mediterranean group of peoples. The high civilization of the Sumerian south penetrated the Semitic-speaking peoples of the middle regions of the valleys, whence arose the Akkadian (Accadian) dynasty under the ruler Sargon. The Akkadians finally absorbed the Sumerians, and out of this mixture emerged the state of Babylon under Hammurabi, the lawgiver, in the 18th century B.C. But the epics and books of wisdom of the Sumerians remained the classical texts of both Babylonians and, later, Assyrians. The Sumerian civilization had invented writing, at first as a practical requirement of the organization of their temples. They used pictograms, later supplemented them with phonetic signs. The form of the society which built the earliest cities has been called theocratic socialism. Its basis was a well-balanced mixed economy in which agriculture, stock breeding and hunting existed side by side. Through the export of rugs and textiles, weapons and jewelry, the influence of Sumerian civilization permeated the whole of the ancient near east.

The Babylonian state collapsed before invaders, the Kassites, from Elam, who controlled Babylon for five centuries. They adopted the civilization and Semitic language of their subjects. The Hittites, who first invaded Babylonia about 1595 B.C., created a considerable empire covering northern Syria and the greater part of Asia Minor in the 14th century B.C. In the archives found at their capital, eight languages are represented, including Sumerian and Akkadian. Subsequently the Assyrians, who seem to have been an offshoot of the Babylonians using almost the same language, asserted themselves and in the 11th century B.C. became the chief power. Their empire gradually broke up, finally succumbing before the Medo-Persian power at the close of the 7th century B.C. Babylon itself was taken by the conqueror, Cyrus, in 539 B.C., but its culture and religion continued to exercise great influence long after the Persian conquest.

In Egypt the cultural continuity was even stronger than in Mesopotamia, and there was never any change corresponding with the displacement of Sumerian by Akkadian in Mesopotamia. Whereas that land was dotted with autonomous cities, Egypt began in the upper reaches of the Nile valley as a royal domain which extended to cover the whole valley and to found a 1st dynasty about 3100 B.C. The administration and major activities of society were centralized to an extreme degree and it was accepted that in the person of Pharaoh, the living king, a god had taken charge of the people. With relatively minor breaks the established order continued for many centuries, Egyptian influence at times reaching eastward to the upper Euphrates. Up to about 1200 B.C. the history of the ancient near east had passed through two main phases, the emergence of the first great civilization in Mesopotamia and Egypt and subsequently the gradual spread of that civilization to the periphery. About 1200 B.C. new waves of invaders broke into Asia Minor and the Levant destroying the Hittite empire and disrupting Egypt, and after this the creative power of the near east waned. Its main achievement was in the consolidation of acquired knowledge. From this period the centres of power move both to the west and to the east of Egypt and Mesopotamia.

As has been seen, Persian power in the 6th century B.C. destroyed the Assyrian empire and in 539 B.C. captured Babylon and created the Achaemenid empire. The Persians, with whom the Medes are often coupled, appear to be Aryan in origin, their language and religion offering remarkable analogies to those of the early Hindus in India. These two peoples appear to have had a common origin in central Asia. The Achaemenid power at its greatest extended from the Oxus and Indus in the east to Thrace in the west and Egypt in the south, but it fell before Greece after lasting for more than 200 years. Darius and Xerxes were repulsed in their efforts to subjugate the Greek peninsula and Alexander the Great conquered their successor, Darius III, in 331 B.C. But the greater part of the empire continued to exist under new masters, the Seleucids, as a Hellenistic power which was of great importance for the dissemination of Greek culture in the east. About the same period (227 B.C.–A.D. 226) the Parthian empire arose under the Arsacids in Khurasan. The Parthians were probably a Turanian tribe who had adopted Persian customs. At one time their power stretched from India to Syria. They withstood the Romans but succumbed to the Persian dynasty of Sassanids who ruled for about four centuries, establishing the Zoroastrian faith as their

state religion and maintaining an equal conflict with the eastern Roman empire. But in the 7th century A.D. their power was overwhelmed in the first rush of the Mohammedan conquest which established Islam in Persia and in the neighbouring lands.

India.—The subcontinent of India is divided from the rest of Asia by the Himalayan mountain ranges. This has by no means kept India in isolation but it has resulted in the growth over a period of two to three millenniums of a Hindu civilization which in many of its aspects is unique. Archaeologists have unearthed the remains of a city civilization on the upper Indus valley which appears to have flourished in the 3rd millennium and to have had affinities with Sumerian civilization, but its inscriptions cannot yet be read and its history is still unknown.

Hindu civilization came about in the 1st millennium B.C. as a result of the intermingling of Aryan and pre-Aryan cultures. Entering India sometime between 1800 and 1500 B.C., the nomadic Aryans settled in the northwest, thence gradually during the 1st millennium B.C. encroaching eastward on the pre-Aryan peoples in the Ganges valley and producing a multiplicity of settled states and a fusion of cultures. Society came to be dominated by a hereditary priestly class of Brahmans. Political multiplicity is a characteristic of India's history and the occasions on which most of the subcontinent was united under one rule were few and relatively brief. Such periods occurred during the Mauryan rule of Asoka in the 3rd century B.C., the Delhi sultanate in the 13th and 14th centuries A.D., the Mogul empire of the 17th century and British rule in the 19th century.

India lacked a common political consciousness probably because its social consciousness had developed so strongly. The Indo-Aryan culture of the northern plains spread across the southern part of the peninsula during the second half of the 1st millennium B.C. and the Dravidian peoples of the south (Tamils, Kanarese, etc.) were at one with the north in accepting Hinduism and the caste system, a division of the population into groups, based partly on race, partly on occupation. In Hinduism, India cradled the oldest surviving world religion. India's greatest achievements lie in the intellectual and cultural field, and its religious and philosophical systems and Sanskrit literature stand among the finest achievements of the human mind. From the 4th century B.C. two scripts were in use—Kharosthi in the northwest and the more important Brahmi elsewhere. From the latter regional modifications developed not only for India but also for central and southeast Asia. Indian grammar, law, architecture, sculpture, painting, music, arts and crafts, such as metal casting, enamel work, jewelry, ivory and wood carving, were highly developed. In India the invention of calculation on a system of nine digits and zero took place. Indian art and science grew directly from its religions and philosophies.

In the main this was a Brahmanical achievement, but in the 6th and 5th centuries B.C. various reactions to Brahmanism began, the most important being the doctrines of Gautama the Buddha, which in the form of Buddhism grew into one of the greatest religions in the world. For many centuries the intellectual development of the Hindus depended mainly on the interaction of Buddhism and Hinduism, but Buddhism was finally absorbed and disappeared in India. But it proved acceptable on the frontiers and spread far and wide. Ceylon was converted. In the northwest it crossed the passes into Afghanistan and moved along the trade routes through Turkistan into China, bearing with it in literature, sculpture and painting, material forms of Indian culture. It passed into Korea and Japan, gradually adapting itself to its new environments. In the 7th century A.D. Buddhism was imposed on Tibet, and that country remains a stronghold of the faith, which there takes the form of Lamaism. To the south, in the early centuries of the Christian era, Buddhism followed the trade routes across the seas to southeast Asia and as a result mixed cultures sprang up in which Indian influences are discernible. In this direction, unlike the movements to the north, Hinduism also followed Buddhism, and petty Indianized kingdoms in Burma, Thailand, Malaya, Indonesia and Indochina were set up and a movement of traders, scholars and travelers took place. Some of the greatest surviving architectural creations in the Indian world, for example, Borobudur and Lara Djonggrang in Java and Angkor Wat in Cambodia, were conceived and built in southeast Asia. The kingdom of Champa in Indochina marked the farthest reach of Indian culture. There it came directly into contact with Chinese civilization which had molded the adjacent empire of Annam. Champa was overrun by Annamite armies in the 15th century A.D.

In general, the contacts between India and the west took place on the material plane. Trade, for example, between the Roman empire and southeast Asia via south India was considerable even in the early centuries of the Christian era. On the whole, western Europe was little affected by India until the end of the 18th century.

Southeast Asia.—The peoples of this extensive region belong to many races, of whom the first with a determinable history were the speakers of the Mon-Khmer languages still used in Pegu and Cambodia. Early in the Christian era Indianized kingdoms were established in Cambodia and in Champa. The Burmese, who are linguistically allied to the Tibetans, entered Burma from the northwest. By the 16th century A.D. Burma had become a united kingdom. The Thais or Siamese, who speak a language of the Chinese type but use an Indian alphabet, infiltrated from southern China and took power in Thailand in the 13th century A.D. The Annamites and Malays are discussed above. All these peoples have been closed about by the cultures of India and of China, and the higher elements of their civilization have been taken from these two primary sources.

China, Japan and East Asia.—Chinese civilization appears in northern China in the latter half of the 2nd millennium B.C. The discovery at An-yang in Honan province in 1899 of thousands of bone fragments, many of them inscribed, has confirmed the existence of the Shang dynasty (*c.* 1523–1027 B.C.), which previously had been thought to be legendary. Early Chinese civilization grew in the Yellow river plain extending southward toward the Yangtze and westward and northward along the Wei and Fen valleys in Shensi and Shansi provinces. During the Chou dynasty (1050–256 B.C.), the great formative age of Chinese civilization, the intervening areas populated by groups of a lower culture were conquered and absorbed.

In Han times (202 B.C.–A.D. 221) the centre of Chinese culture was still in the north but by the Sung dynasty (960–1279) the Yangtze valley began to outweigh the north in population and importance. Chinese expansion to the north, which reached the steppelands during the Chou dynasty, was much slower and it came to a halt on the steppe, among the nomadic herdsmen, where the Chinese system of settled agriculture could not be applied. This conflict between two ways of life resulted in the building by the Chinese of a series of defensive walls, finally linked together by the Ch'in dynasty into the Great Wall.

Korea and Annam came under Chinese dominance in the Ch'in-Han period, but the former broke free again in the 4th century A.D. and the latter in the 10th century. Both absorbed Chinese culture. On the other hand, Japan, which was a united power by the 4th century A.D., never came under Chinese rule. However, Japan received the first elements of higher culture from China through Korea and in later times Japan set itself with determination and success to absorb Chinese culture.

In early historical times in China, society was dominated by a hereditary ruling class whose religion, involving the cult of heaven and of the family and clan, was not shared by the masses. The rulers were the custodians of the written language and of the traditions, and the scholars among them gradually formed during a period of political troubles a system of ethics and political theory which the philosopher Confucius preserved and transmitted to posterity. These thinkers, moreover, had evolved the rational ethical ideal of the ruler, the "son of heaven," holding the mandate of heaven but not himself divine and capable of being replaced if his conduct betrayed his position. Theirs, too, was the ideal of the supremacy of learning and of the scholar-ruler which became the accepted standard of the mandarin administrators of imperial China.

Many centuries passed, however, before the ideal of government through bureaucracy, selected on the basis of learning, reached its

fulfillment. Not until the T'ang dynasty (A.D. 618–906) was the examination system, through which the mandarins were selected, functioning fully. This administrative system undoubtedly provided the backbone of the remarkable political continuity of the Chinese empire and helped to strengthen the ideal of political unity, "all under heaven," which was throughout a feature of Chinese political theory. The actual achievement of unity under the Ch'in dynasty (221–207 B.C.) set the standard for the following 2,000 years, a unity which persisted through about 20 successive dynasties. Different as was the empire of the 19th century A.D. from that of the Ch'in, it had in fact undergone no major political revolution in the interim. Rebellions might take place, provinces might break away, rulers might change or be changed, but the system persisted.

China's artistic achievement, like its ethical and political system, was greatly influenced by the scholar bureaucracy. This is especially true of those arts that were based on the written character, whether in the form of literature or calligraphy or a great deal of Chinese painting. But the main stream of Chinese culture was also affected from the outside. New ideas, especially in the early centuries of the Christian era, entered freely from India and the Iranian world. Of these Buddhism was much the most important, competing with Confucianism for the allegiance of the upper classes, deeply penetrating the later Taoist religion and providing a pattern for the organization of the Taoist Church. With Buddhism, too, came a deep influence on all Chinese art.

An outstanding characteristic of Chinese civilization was its inventiveness which produced, among other things, paper, printing, gunpowder, the mariner's compass, the sternpost rudder and the wheelbarrow. Chinese silks, ceramics, jades and bronzes early found a market in other parts of Asia and in Europe. The expansion of the Former or Earlier Han dynasty (206 B.C.–A.D. 8) into central Asia opened up a major caravan route through Turkistan which for centuries provided a link with the Roman world. China's relations with the nomad peoples affected the movements of peoples throughout central Asia, from time to time creating repercussions in the near east, in Europe, in northern India and Iran. By the 2nd and 3rd centuries A.D. a southern sea route was opened from India and the west around Malaya to Annam and south China; and by these land and sea routes trade and travelers passed freely. After the rise of Islam in the near east, trade by sea flourished and Arab ships were to be seen at Canton and Chinese junks in the Persian gulf.

In the 8th century the caliphate and the T'ang empires came into direct land contact and conflict (A.D. 751). Overland contact, interrupted from time to time by the pressures of the steppe peoples was maintained from this time until the 13th century. Then a sudden major outburst of the Mongols created for a short period a single empire reaching from south Russia to the Pacific, allowing Europeans for the first time to visit and write about China. The Mongol empire soon dissolved, but the legend of Cathay (*q.v.*) that was born in European minds lived on, and in the 16th century played its part in inducing the Portuguese to venture round the Cape of Good Hope and the Spaniards to cross the Pacific. Thus there came to the west a more detailed knowledge of Chinese civilization which in the 18th century created in Europe a craze for things Chinese. But by this time the Chinese Manchu empire was decaying, its administration rotting with corruption and its inspiration dead.

As seen above, Japan had early begun to assimilate Chinese culture and in A.D. 645 a deliberate and wholesale introduction of Chinese forms of government took place. But the administration remained subordinate to a number of great landed warrior families who fought among themselves for control of the country. The Fujiwara, the Taira and the Minamoto bore the brunt of the struggle, the latter emerging victorious and in A.D. 1192 establishing a dual system under which an emperor ruled in name while the real power rested in the hands of a hereditary military chief called the shogun. This system was carried on by the Ashikaga family (1336–1568) and the Tokugawa family (1603–1867). In the 16th century the Portuguese reached Japan and attempted to introduce Christianity. In the resulting ferment, ideas of conquest developed among a remarkable group of leaders, one of whom, Hideyoshi, organized the invasion of Korea. Death interrupted his plans and a reaction set in under his successor, Ieyasu, who decided on a policy of isolation. Christianity was forbidden and Japan was closed to foreigners, and it so remained until after 1854. The early history of Japan was chiefly remarkable for the single-minded way in which its people were able to close ranks and follow a set line of policy such as deliberately setting out to copy Chinese culture, adapting Chinese forms of government or shutting out the foreigner.

Islam.—The term Islam (*q.v.*) covers the peoples and states that accepted the faith and law of Islam and professed to live by them. Islam begins with the life and teaching of the prophet Mohammed in Arabia in the early 7th century A.D. The first Muslim state in Medina erupted in successive waves of conquest over Arabia into the fertile crescent and across Persia into central Asia. Its influence reached into China and northern Asia; at the same time it had also pushed westward across northern Africa to the Atlantic. Fresh impulses of conquest took Islam into southern Europe and through Spain into France. By sea first and then by land Islam was also carried into India, thence by sea again southeastward to Malaya and the East Indies. However, the heart of the Islamic world was and is the near and middle east. The caliphate under the Omayyads (Umayyads) of Damascus (661–750) and then the Abbasids of Baghdad (750–1258) became the principal power.

Wherever Islam was accepted it carried with it a sense of unity based on its strictly formulated faith and on its holy law which, despite much variation of custom over so vast a zone of conquest, remains a common ideal and pattern of belief and conduct for the whole Muslim world. Wherever it has gone it has taken its language, Arabic, which is the holy tongue of Islam, the language of the Koran and of the traditions of the Prophet. Almost all the languages of the Muslim world have borrowed heavily from Arabic and are written in its script. The art and architectural forms of Islam, too, are distinctive, proclaiming the unity of the Islamic cultural pattern. Through their military and political power, reinforced by their culture, the Muslims brought together two formerly conflicting worlds, the diversified Mediterranean tradition of the ancient near east, Greece and Rome and the rich civilization of Persia, a fusion which produced great scientific and philosophic developments. Islamic scholars preserved something of the heritage of Greek antiquity, which was later handed on to Christian Europe. Through the Arabs the Chinese art of paper-making and the Indian system of numerals reached Europe.

Arab power was explosive and quickly burned itself out and by the 11th century A.D. fissiparous tendencies produced a singularly complete collapse of the empire of which the European crusaders and traders in the 12th and 13th centuries took advantage by invading the near east. But the peoples on the periphery carried Islam with them. The khanate of the Golden Horde, which between 1241 and 1395 ruled from the Danube to the Urals, was a Muslim state as also were its successors in the Crimea, the Caucasus and the Volga. In the 14th century the islamized Ottoman Turks brought large areas of Europe under Muslim rule and created an Ottoman empire which lasted until 1922. Muslim dynasties ruled in Persia, and Islam was carried through central Asia in two main waves into north India by the Turks (1000–1526) and the Moguls (1526–1707). The Muslims never fully subjugated south India but their rule in the north under such rulers as Akbar and Shah Jahan was brilliant, both politically and culturally. But Hindu powers, especially western India, struck back at the Muslims in the 17th century, creating disorder and disrupting the empire. In these disturbed conditions European trading companies already established on the Indian coasts, especially the English and the French, were drawn in to compete for political supremacy.

Through trade Islamic influence had reached out in the 16th century from India to Malaya and Indonesia, peacefully overlaying Hindu culture in the main centres, though not in Bali.

The influence of Asia on Africa was until the 19th century greater than that of Europe. The ancient near east drew on the resources both in men and material of the regions beyond the

upper Nile valley. The ancient Abyssinian kingdom was founded by Semites from southern Arabia, and Islam penetrated both north and south of the Sahara across to west Africa. There was a continuous Arab migration to east Africa which founded a series of cities on the coast. There was also an ancient connection between India and eastern Africa, which was reinforced in the 19th century by Indian immigration.

The great civilizations of Asia spread out over immense areas. Although they were separated one from the other by distance and slow communication, their contacts were numerous and between them the cross-fertilization of ideas and material culture was extensive. They were slow growing and slow changing, based in the main on subsistence economies. Their upper classes, however, created an active trade in ideas and luxury goods and in each civilization developed a way of life, whether Indian, Chinese or Islamic, that was chiefly remarkable for its inner harmony. Each religion or ethical code formed a way of life for its peoples and all aspects of life served to express this. Nevertheless, that their ways of life were very different one from the other is to be seen, for example, in their respective attitudes to history. The Chinese regarded the writing of their own history as an important state function and a significant branch of literature. Official historians were regularly at work producing official histories of each dynasty. In this way the doctrines of Confucianism were perpetuated and the official record of the times was made to conform to the accepted doctrines. What man did in this life on earth was taken to be supremely important. The civilizations of the ancient near east and of Islam produced histories and chronicles justifying the ways of God to man and in the case of Islam seeking to show that a good Muslim would certainly be a good ruler or a good subject. What a Muslim did on earth was necessarily important. In striking contrast the Brahmans of India disregarded their own history. Consistent with their view of life, they did not regard the recording of man's practical activities as of any significance compared with spiritual issues. These differences illustrate the fact that oriental civilizations did not find uniform solutions to their problems.

Asia and Western Dominance.—At the close of the 15th century, that is, about a quarter of a century before the Moguls began to conquer northern India and a half-century before the last great dynasty of China (the Manchus) established itself, a Portuguese fleet under Vasco da Gama found its way around the Cape of Good Hope into Indian waters. While the Moguls went on to conquer the Indian mainland, the Portuguese made themselves masters not only of Indian waters but of all the eastern seas. Where they led, the Spanish, Dutch, French and English followed. Above all, trade was sought, especially in silks and spices, but various attempts were also made to spread Christianity, especially by the Portuguese, who had themselves felt the proselytizing impact of Islam in Europe and north Africa and were not reluctant to carry the fight to the east.

During the 15th to the 19th centuries Europe itself was changing rapidly. Nation-states, perhaps as a solvent of religious wars, were growing up. The foundations of a scientific, industrial and technological revolution were laid. Europe learned how to navigate the oceans, apply sea power, wield artillery, organize representative government, cultivate religious toleration and use money and credit in trade. Thus it was a supremely confident Europe that began to feel its way along the coasts of the traditional, slow-changing societies of Asia.

The Portuguese quickly established themselves in Goa and Macáo; the Spanish took the Philippines in 1565. The rivalries of Europe were extended to Asian waters and the Dutch evicted the Portuguese and consolidated a spice empire in Java and Sumatra, centring on Batavia. Between 1740 and 1805 the French and British on the coasts of India fought a severe struggle for supremacy, which the latter won, in the process being drawn into the vacuum which the collapse of the Mogul empire had created. During the 19th century British power easily spread across India to the Himalayas and the whole subcontinent and its peoples became a major field of British investment. To protect this, new British bastions of power were erected in Aden, Persia, Arabia, Burma and Singapore.

Meanwhile the French, pushed out of India and forestalled in Burma, established control over Cochin China, Annam, Tongking, Laos and Cambodia. The independence of Siam (Thailand) was preserved because of its buffer position between the British in Burma and the French in Indochina.

In the near east, the Ottoman empire was crumbling under internal stresses and external pressures. In 1882 the British took control of Egypt in order to safeguard the new route to India through the Suez canal (1869), and the French, who had already crossed the Mediterranean into north Africa, later found a foothold in Syria. The far east was to some extent protected by distance and the rivalries of the European states elsewhere, but in 1842 and thereafter China was forced to open some of its ports to foreign trade and residence and to accept treaty provisions giving a special position to foreigners, a status which was substantially maintained until the 1930s. Beginning in 1854, the United States opened Japan, under arrangements similar to those forced on China.

Meanwhile across central and northern Asia Russia was advancing by military force, political manipulation and colonization. By 1900 Russia was established on the Pacific coast, and both China and Korea were being threatened from land and sea.

The Recovery of Asia.—By this time the peoples and governments of Asia had begun to react to the impact of Europe. Their 20th-century history is largely the story of change looking toward recovery of full independence and political and economic modernization. Japan, a tightly organized, compact island state, moved first by again making a deliberate decision to acquire the material power and organization of the apparently superior power, this time the European. By 1894 the legal and judicial order had been modernized; a new school system had been created; the foundations for a modern economy had been laid; the military system had been modernized; and a constitutional system had been established (1889). These changes enabled Japan to negotiate revision of its treaties, establishing legal equality with the western states. Its new power also enabled Japan to defeat China in 1894–95 and Russia in 1904–05. These two wars enlarged Japan to include Formosa (1895) and Korea (1910) and gave it a position in Manchuria from which to move in empire building on the Asian mainland.

European domination in Asia, together with the introduction of "western learning" into Asian countries, gave rise to nationalist movements. Capitalist enterprise and higher-education policies in the Islamic world, China, southeast Asia and India had brought into existence a new intellectual and middle class, the members of which respected the scientific and industrial revolution of the west and wanted to emulate it. They sought to introduce into their several countries the political and economic institutions of the west, but at the same time to reject western political and economic supremacy. Everywhere in Asia nationalism and anticolonialism formed the co-ordinates of these movements. Although nationalism itself, together with the presence and dominance of European powers, tended to isolate the Asian countries into self-contained units, the individual nationalist movements interacted on each other. The victory of Japan over Russia and the early successes of the Chinese reform and revolutionary movements stimulated action elsewhere in Asia. The rise of the freedom movement in India encouraged similar developments in Ceylon, Burma and Indonesia. The revival of Islam in the near east after World War I stimulated Muslim consciousness in India and southeast Asia.

In China the first reaction to the western impact was anti-Manchu as well as antiforeign. The failure of the Boxer movement (1900) inaugurated a period of Manchu reform designed to avoid revolutionary change. Revolutionaries were, however, successful in replacing the dynasty with a parliamentary republic in 1911–12. The traditional provincialism, however, soon made ineffective the national parliamentary republic, although China as a state retained its identity against pressures both from the west and Japan. National political unity began to be re-established when the Nationalist party took over the government of China (1928). Concurrently with the nationalist phase of the Chinese revolution Marxist-Leninist ideas were introduced into China with the organization of the Chinese Communist party, affiliated with the Communist international. In the ensuing struggle the Nationalist

government maintained its ascendancy until 1949. The establishment of the People's Republic by the Chinese Communist party not only inaugurated the Communist phase of the Chinese revolution but also enabled Chinese and Russian influence to replace western in a number of peripheral areas.

In the Indo-British empire an effort was made by the British to establish forms of representative and responsible government. But the attempt to hand over power roused the self-consciousness of the Muslim and Hindu communities so that the subcontinent when freed in 1947 was also partitioned into two independent countries—Pakistan and India. Nationalism had been sufficiently strengthened in Burma and Ceylon during World War II so that Britain was obliged to concede independence by 1947. A new relationship with Malaya was similarly established a decade later, and in the late 1960s only Brunei and Hong Kong remained under British control. Other European imperial powers in Asia, weakened by World War II and the temporary overrunning of southeast Asia by Japan, in time yielded their positions. The Dutch gave way to the Indonesian nationalists in their colony (1949), and the French, by 1954, had been compelled to withdraw from Indochina. The United States fulfilled its promise to grant independence to the Philippines in 1946. The U.S. occupation of Japan was officially terminated by the peace treaty which became effective in 1952 but U.S. forces remained under the terms of a security treaty. Sustained U.S. military involvement in Korea (1950–   ) and later in southeast Asia were exceptions to the broad retreat of Western power from the Asian scene.

After World War II the idea of the nation-state was firmly planted in all Asian countries. Internal political and economic stability, however, had not always been fully established following independence. In the background the U.S.S.R., on the landward side, strengthened its grip on central and northern Asia, and the United States, on the seaward side, sought to fill the power vacuum left by the Japanese defeat in the Pacific. Communist China emerged as a major power opposing the U.S. and, from the early 1960s, publically divided from the U.S.S.R. In the near and middle east the Arab and Muslim states had regained or reasserted their independence, but they were small, weak and divided. Continuing hostility to the new Jewish state, Israel, after its proclamation (1948), as well as fear of European domination, served as an Arab bond of union. Turkey, which had become a republic in 1923, deliberately abandoned Islam as the state religion and under Mustafa Kemal Atatürk began to turn itself into a modern westernized nation-state.

Economic and social developments in Asia had not kept pace with the rate of political change. An enormous increase in population, especially in India, China and Japan, had occurred and, except in Japan, the masses were probably poorer at the close of the period of European dominance than they had been at the beginning. The disparity between the masses and their new, mainly middle-class rulers had become more glaring than ever and the new nations of Asia, though free, were neither secure nor stable. This situation opened the way for the introduction of the essentially European program of Communism in competition with western democratic capitalism. In short, the influence of the west had created revolution in Asia and had complicated, not simplified or clarified, the problems facing Asians.

V. POPULATION

By the late 1960s, nearly 2,600,000,000 people, about 60% of the world's population, lived in Asia exclusive of the Russian portion. For the most part, this massive population is composed of village-dwelling, agrarian peoples, concentrated on the better agricultural areas where population densities are extremely high, and characterized by high fertility rates which are basic to high rates of natural

ADAPTED FROM GEORGE B. CRESSEY, "ASIA'S LANDS AND PEOPLES"; REPRODUCED BY PERMISSION FROM MCGRAW-HILL BOOK COMPANY, INC.

FIG. 6.—POPULATION DISTRIBUTION OF ASIA

increase, both actual and potential. Urban-industrial population concentrations, while important in Japan and a few other areas, are not characteristic and have had little effect upon the great mass of the Asian population.

Distribution.—The average population density of fewer than 100 persons per square mile for Asia as a whole (including the portion in the Soviet Union) is less than half the comparable figure for Europe. But an average is hardly descriptive of such a large and varied continent. In the north are several million square miles of sparsely populated subarctic tundra and forest lands, with permanently frozen ground and large areas of swamp. Central Asia, including Mongolia, the western half of greater China and Russian Turkistan, is an area of deserts, mountains and high plateaus, where dense populations are restricted to irrigated oases. Aridity applies a similar limitation to much of southwestern Asia from Iran to Turkey and Saudi Arabia.

In contrast to these large sparsely populated sections, Asia also contains the world's largest areas of densely populated agricultural land. In east, southeast and south Asia live 90% of the continent's total population on less than half (actually a third if west China be excluded) of its land area. The most populous areas lie in crescent-shaped monsoon Asia extending from West Pakistan to northern China and Japan. In most of monsoon Asia the climate is humid, tropical or subtropical, with a marked maximum of precipitation occurring in the summer. The rainfall regime and topographic influences result in a striking development of fertile alluvial flood plains and deltas along the lower courses of monsoon Asia's rivers, from the Indus in Pakistan to the Yellow river in north China.

In this large section of Asia the traditional and still dominant basis of livelihood is agriculture, with emphasis on irrigated rice wherever its cultivation is possible. Densities are extreme. Trewartha's maps show a minimum of 400 persons per square mile on the extensive alluvial plains of eastern China with densities in excess of 900 over large areas. Rural densities as high as 2,000–3,000 persons are revealed by detailed data for smaller areas in most countries of monsoon Asia. The occurrence of these alluvial lowlands sets the gross pattern of population distribution. But the lower densities in less-favoured areas such as south China (hilly terrain), parts of southeast Asia (poor soils) and peninsular India (less and more variable rainfall) should not obscure the fact that in these areas also agricultural populations press against the limits of available resources.

Monsoon Asia thus contains two of the world's three great masses of population, each occupying an area larger than Europe, with a higher average density and more people than any non-Asian continent. In east Asia is the largest of these masses with its demographic centre in eastern China, where more than 700,000,000 Chinese constitute the largest group of ethnically and culturally unified people on the earth's surface. The second major population mass is in south Asia with over 600,000,000 people in Afghanistan, Pakistan, India and Ceylon. Between these two masses is southeast Asia, more fragmented in form and more diverse in its demographic character. The densely populated areas on alluvial lowlands of the mainland and in Java, with its fertile volcanic soils, contrast with large areas of sparse population where infertile lateritic soils, rough terrain or the presence of endemic diseases inhibit intensive development.

Only in Japan, the most industrialized country in Asia, has urbanization reached western levels. About three-fifths of the Japanese live in official cities (*shi's*), and six major cities of more than 1,000,000 inhabitants have a total population in excess of 16,000,000. Elsewhere the large Asian city has usually been a port or an administrative centre developed as a result of western influence and epitomizing the duality that characterized the economy, especially of colonial territories. After World War II the withdrawal of colonial control was accompanied by a rapid growth of cities. The number with populations of at least 1,000,000 increased from 13 in 1935 to 31 at mid-century, with comparable increases in the number and population of smaller centres. However, the development is too recent to have altered very much the numerical and cultural dominance of the rural and village populations.

Population Trends.—For centuries the high birth rate of Asia's population has been associated with intensive rice culture, cohesive village life and family-centred social organization. Demographers hold that the population increase which quintupled the population of Asia in the period 1650–1950 was largely due to decrease in the death rate, while birth rate and the underlying conditions affecting it remained relatively unaltered. After World War II the use of modern insecticides and antibiotics resulted in even more spectacular reductions in death rates, still without fundamental change in economic or social conditions. Several of the smaller countries from Japan to Iraq have death rates comparable to those of the western world. Where the birth rate remains at "Asian" levels, population increases substantially above 2% per year are the result, as in Ceylon and southwest Asia. Japan is the only major country where a sharp reduction in the birth rate has led to a marked decline in the rate of population increase. However, in India and Formosa in the 1960s, and from time to time in China also, there was official advocacy of family limitation and support of educational and technical programs to facilitate birth control. These, obviously, represent a major departure from traditional attitudes.

For the future the most that can be said is that Asia retains the potential for tremendous population increase because of the size of the population and its favourable age distribution, as well as the underlying social and economic conditions and widespread cultural attitudes. Irene Taeuber sets the possible population of Asia (excluding the Soviet portion) at from 2,900,000,000 to 4,200,000,000 by the year 2000, but is careful to point out that a forecast is impossible in view of the many variables involved. Meanwhile the presumed 2% increase of China's population adds about 15,000,000 Chinese per year in contrast to the annual increase of about 3,000,000 persons in the entire Soviet Union.

Soviet Asia.—Population in the Russian portion stands in contrast to the rest of Asia in terms of numbers and density and in most other respects as well. In Soviet central Asia and the Caucasus live Asian peoples, long settled on densely populated, irrigated oases, or engaged in extensive animal raising on subhumid grasslands. More significant, however, has been the influx of population from western Russia with the attendant development of rail and other transport facilities and a western-type, commercial, mechanized agriculture. Major development of mineral and manufacturing industries with the accompanying growth of cities has been particularly significant in west and central Siberia, but by no means lacking in the eastern and southern sections. Soviet Asia remains a frontier area where the economy and population grow because of immigration. Elsewhere in Asia the closest parallel to this type of pioneering has been the movement of Chinese into Manchuria after about 1900 and the later development of northwestern China under the Communist regime.

ASIA, ROMAN PROVINCE OF, the first and westernmost Roman province in Asia Minor, stretching at its greatest extent from the Aegean coast in the west to a point beyond Philomelium (Aksehir in the modern Turkish *Il* of Konya) in the east and from the Sea of Marmara in the north to the strait between Rhodes and the mainland in the south; thus it comprised the Troad, the coastal cities, Mysia, Lydia, western Phrygia and, south of the Maeander (Buyukmenderes) river, Caria. The province was first constituted when Attalus III, king of Pergamum (*q.v.*), bequeathed his dominions to the Romans in 133 B.C. It then contained many different communities at different stages of development: the old Greek cities on the coast, newer hellenistic foundations, native towns already largely hellenized and indigenous peoples still living in tribes and villages about their tem-

ples. The province was rich in natural resources, and its dyestuffs and woolen textiles were famous. Under the Roman republic, however, its prosperity was ruined by commercial exploitation, taxation and war, so that the advance toward hellenization and urbanization begun under the Seleucid and the Pergamene kings was impeded, Mark Antony left an exhausted province for Augustus after the battle of Actium (31 B.C.).

Recovery under the empire was rapid and secure. A peaceful province, Asia remained senatorial in the division of provinces between Augustus and the senate and was governed from Ephesus by a proconsul of consular rank (under the republic the governor had usually been a former praetor) assisted by three legates and a quaestor. Besides these the procurators who administered the imperial properties and imperial taxes became increasingly important. For the administration of justice, the province was divided first into nine *conventus* (assize districts), later into more. The provincial assembly, called the *koinon* of Asia, to which the cities sent representatives, met annually in different cities, chose the officials known as Asiarchs and also high priests for the official worship of the emperor, passed resolutions, made appeals and sent deputations on provincial matters. The older cities retained their traditional councils, magistrates and assemblies in the Greek form, and new ones were steadily added as prosperity increased and hellenization advanced. The Roman businessmen and the Roman colonists were assimilated to their neighbours.

The great cities of Asia—Pergamum, Ephesus, Miletus, Sardis, Smyrna (*qq.v.*) and many more—were leading educational and cultural centres. Important Christian communities and bishoprics grew up within the province (for example, the Seven Churches of Asia), and important heresies, such as Montanism, also. The province shared in the sufferings and decline of the 3rd and the 4th centuries and lost much in economic importance as the development of the Balkan provinces, military needs and the founding of Constantinople turned the empire's main lines of communication away from the Aegean toward the northwest. Yet its reserves of products and manpower and its relative immunity from devastation made it an important factor in the survival of the Eastern Roman empire. Under Diocletian it was divided into seven provinces: Hellespontus (Troas and Mysia), Insulae (islands off the coast), Asia (the coast from Assus to the Maeander), Lydia, Caria, Phrygia Prima and Phrygia Secunda, most of them in the diocese of the East. There remained, however, a proconsul for Asia directly responsible to the emperor.

ASIA MINOR, the broad peninsula (area *c.* 287,000 sq.mi.) which comprises the main (Asian) part of the modern republic of Turkey. To the east, its landward limit may be conveniently placed at the Anti-Taurus mountain ranges, since these not only form a watershed separating the drainage to the Black sea and Mediterranean from that which flows to the Caspian and the Persian gulf but they are also an important strategic and ethnic barrier. The Byzantine emperors for four centuries used the outer range of the Anti-Taurus as their military frontier against the Arabs; and nowadays the chief minorities of the Turkish state live east of this mountain divide.

The Black sea on the north is linked to the Aegean sea and Mediterranean (on the west and south) by the Sea of Marmara which, with its two famous straits of Bosporus and Dardanelles, separates European from Asiatic Turkey. Asia Minor contains the main land links between Europe and Asia and has often been the scene of struggles between occidental and oriental civilizations.

The term Asia Minor, the earliest use of which, in its modern sense, is in the *Historia adversus Paganos* of Orosius, who wrote in the 5th century A.D., was probably applied in the first instance to the Roman province of Asia to distinguish it from the continent. The name Anatolia—the Levant—may be taken as synonymous with Asia Minor. It was first used by Constantine Porphyrogenitus in the 10th century A.D. and was later taken over, in the form of Anadolu, by the Turks, who used it, like Rum (*q.v.*), to mean roughly the territory which was conquered from the Byzantines.

This article contains the following sections and subsections:

I. PHYSICAL GEOGRAPHY

Asia Minor is a predominantly mountainous peninsular projection of southwest Asia and a western prolongation of the high Armenian plateau.

1. Geological Structure.—The peninsula forms part of the belt of Tertiary fold mountains which crosses the old world latitudinally from Portugal to the Malay archipelago. These mountains are built from the detritus which accumulated in the depths of the Tethys sea, and as they were thrown up they were often moulded round the edge of ancient stable blocks which had formed islands in that sea. In Asia Minor the central plateau is such an ancient block, and round it were shaped the multiple ranges of Pontus in the north and Taurus (Toros Daglari) and Anti-Taurus in the south.

After the mountains were built, the structure of the country was further complicated by rifting and subsidence. The whole of the Aegean, for example, is a collapsed part of this system of fold mountains, like the fallen keystone of an arch. This rifting was frequently followed by the outpouring of volcanic rocks and, finally, the landscape was further modified by erosion. There are many signs that the processes of mountain building have only recently become quiescent in Asia Minor; for example, the earth tremors which frequently afflict the Troad, the hot springs and poisonous gases which issue from the ground in some places in Caria, the perpetual flame at Yanar Tas (the "Lighted Stone") in Lycia and the flows of unweathered basalt which in ancient times earned for part of Lydia the name of Catacecaumene, the "Burnt Land." Asia Minor has now no active volcanoes, though Strabo (xii, ii, 7) mentions fire pits which in his day were a danger to straying cattle on the plains below Mt. Argaeus (Erciyas Dagi).

2. Relief and Drainage.—The central plateau is an ancient block overlaid with late Tertiary fresh-water strata and in part also with deposits of soft volcanic tufa which weather into cones and pinnacles of fantastic shape. The general level of the plateau rises from about 2,500 ft. above sea level in the west to 4,500 ft. in the east. In the southwest the ranges of Sultan Daglari and Emir Daglari, outliers of the Taurus system, break the level surface of the plateau, while elsewhere ancient volcanoes frequently protrude. The chief of these lie near the front of the Anti-Taurus, namely Erciyas Dagi (12,848 ft.—the highest point in Asia Minor), Hasan Dagi, Karaca Dagi and Kara Dag. Sometimes these intrusive trachytic masses were used as citadels, like the heights of Old Ankara and the precipitous rock which commands the city of Afyonkarahisar (Afyon).

On the southern side of the central plateau, the ranges of the Taurus sweep in a wide curve from the lake region of Phrygia first to the southeast and then northeastward to the north of Cilicia. There they are joined by the ranges of Nur Daglari

(Amanus or Gavur Daglari), which are probably continuous structurally with the Karpas range of northern Cyprus. The combined Taurus and Amanus systems continue as the Anti-Taurus and merge into the Tunceli (Dersim) and Bingol massifs of the upper Euphrates basin. The coastal plain of Cilicia lies in the angle between the Taurus and Amanus folds, in the same way as the lowland of Pamphylia is contained between the western extremities of the Taurus and another system of fold mountains which run north and south through Lycia. All these mountains of the south and east of Asia Minor, which rise in places to 10,000 ft., are built mainly of Eocene and Cretaceous limestones. They consist of a series of ranges, disposed in echelon, and in the Anti-Taurus in particular they form a broad belt more than 50 mi. across, including high plateaus and basins. In Lycia and southern Phrygia, where two fold systems meet, these depressions among the mountains are especially common and often contain lakes.

On the northern side of the peninsula, the Pontic ranges make a gentle double bend which is reflected in the outline of the southern shore of the Black sea. These mountains, which reach a maximum height of about 6,000 ft., are wider and lower than those of the Taurus and Anti-Taurus and are also much more dissected by rivers, partly because the rainfall is heavier there and partly because porous limestones are not so common and more of the drainage keeps to the surface. The deep and often isolated river plains (*ovas*) among these mountains, such as those of Tokat and Amasya, are more fertile and populous than the high basins of the Taurus, which are in many cases drained by underground escape channels. The Pontic ranges are constructed of Mesozoic rocks, mainly Cretaceous but with Jurassic and Triassic outcrops toward the west where, in the coastal district of Eregli and Zonguldak, Carboniferous strata near the surface contain Turkey's only important deposits of coal.

In the west of Asia Minor, the fold ranges run latitudinally, and the two main valleys between them, those of the Buyukmenderes (Maeander) and Gediz (Hermus), have been widened by rifting to form easy corridors leading from the coast up to the plateau. To the south of these natural routes, the districts of Caria and southern Lydia are higher and more isolated, for there parts of an ancient stable block of serpentine and schistose rocks outcrop among the newer fold mountains.

Coasts.—While the north coast of Asia Minor and most of its south coast run parallel to the grain of the relief, the fold mountains meet the sea transversely in the west and produce an irregular shore line with deep indentations and offshore islands. In the southwest, the north- and south-trending ranges of Lycia again meet the coast squarely, and there are deep natural harbours, like Marmaris Limani, of great strategic though of little commercial importance.

In the Sea of Marmara, too, the Pontic ranges meet the coast at right angles, producing the deep inlet Izmit Korfezi, while the nearby Golden Horn (Halic), the port of Istanbul, is a tributary annex of a drowned river valley, the Bosporus (Istanbul Bogazi). The Dardanelles (Canakkale Bogazi, ancient Hellespont) marks the line of another valley flooded by an irruption of the sea and, like the Bosporus, gives the illusion, with its powerful southward-flowing current, of being a wide river. By contrast, the smooth north coast has no good natural harbours, the chief anchorages being in the wide bay of Samsun and behind the promontory of Sinop. The south coast from Pamphylia eastward suffers from the same deficiency, and the ports of Antalya (Adalia), Mersin and Iskenderun (Alexandretta) all have very indifferent natural shelter.

Many of the details of the coastal outline of Asia Minor have been markedly changed since classical times as a result of very rapid silting by the rivers. This process cannot be attributed to any natural cause, but appears rather to be a consequence of the decline in the standard of cultivation which began at about the start of the Christian era and which was followed by the abandonment of hillside terraces and by the extensive spoliation of forests.

Drainage.—The rivers of Asia Minor vary greatly in depth from summer to winter and, being also frequently of irregular gradient and encumbered in their lower courses with silt, they are of little use for navigation, though they often provide water for irrigation.

In the west and southwest, the Gediz, Buyukmenderes and Koca (Xanthus) run conformably to the grain of the relief. In the north, however, the three main rivers, the Sakarya (Sakaria, Sangarius), Kizil Irmak (Halys) and Yesil Irmak (Iris), and their tributaries cut across the trend of the mountains, partly by keeping to courses established before the mountains were built and partly as a result of "capture" by streams cutting back from the coast. The Kizil Irmak in particular has encroached on the drainage of a wide area of the northeastern plateau, through which the river sweeps in a broad arc.

The southward-flowing rivers of Asia Minor have not cut so far back into the plateau as have those which enter the Black sea. This is the result in part of the smaller rainfall of the southern mountains and to some extent also of their limestone rocks, which absorb much of the runoff into subterranean channels. The Seyhan (Seihun, Sarus) and Ceyhan (Pyramus) rise in the heart of the Anti-Taurus and flow partly within and partly across the ranges before entering the sea over the plains of Cilicia. Farther west, the Gokoluk (Yesiloluk), one of the headwaters of the Tarsus (Cydnus), has cut almost through the Taurus ranges to Pozanti to form the famous pass known as the Cilician Gates. Between this river and the Koca of Lycia, however, the Goksu (Calycadnus) is the only river of appreciable size which flows from the Taurus, and it has cut a deep gash southeastward through the ranges from the plateau to the sea at Silifke (Seleucia).

Although there is so little surface drainage in the Taurus mountains, large streams fed by rain in the autumn and by melting snows in the spring flow underground both to the north and to the south. On the north side of the Taurus, these hidden streams are largely responsible for replenishing the waters of a series of lakes, of which the principal, Egridir (Limnae) and Beysehir (Beishehr, Karalis), have no outlet to the sea. The overflow of Beysehir drains northward, where it irrigates the gardens around Konya before being lost in the loose sands and gravels of the central desert.

The heart of the plateau is itself a basin of inland drainage and, as its name implies, the Tuz Golu ("salt lake") is a shallow sea which recedes each summer to leave a desolate expanse of incrusted salt.

Natural Routes and Passes.—The only wide and easy approaches to the plateau of Asia Minor are from the west, up the valleys of the Sakarya, the Gediz and the Buyukmenderes. These three routes reach the plateau at the cities of Eskisehir (Eski-Shehr), Afyonkarahisar and Dinar (Dineir), while at their seaward ends they are commanded in the first case by Istanbul and in the other two instances by Izmir (Smyrna).

The plateau is crossed by two main routes, one keeping to the foot of the northern ranges, the other skirting those of the south. In each case the road follows a chain of mountain-foot oases that make use of the waters which drain inward from the border ranges to the central plateau. The northern route passes from Eskisehir through Ankara (Angora) to Kayseri (Caesarea Mazaca), the southern from Dinar past Afyonkarahisar, Aksehir and Konya (Konia) to Ulukisla. Kayseri and Ulukisla, which are joined by a route through the oases of Nigde and Bor, thus completing the circuit of the central plateau, are the bases for the main passes of the Taurus and Anti-Taurus. The three passes commanded by Kayseri are those through Sivas to Malatya, through Darende to Malatya, and through Goksun to Maras, while from Ulukisla a single narrow road, in part widened by cuttings in the solid rock, leads through the Cilician Gates (Kulek Bogazi) to the coastal plains, from where the road to Syria has to make a further crossing, by the Bahce or Belen passes, over the Amanus.

Apart from the Cilician Gates, the only important approaches from the plateau to the south coast are down the Goksu valley from Karaman and over the mountains from Burdur to Antalya, but in each case the way is long and difficult compared with that through the Cilician Gates. As a result the plain of Pamphylia and the coasts of Cilicia Trachea have always been much more isolated from the plateau than has the lowland, Cilicia Pedias,

ANCIENT PROVINCES AND TRADE ROUTES OF ASIA MINOR. MODERN NAMES APPEAR IN PARENTHESES

The tortuous and often constricted valleys of the Kizil Irmak and Yesil Irmak do not open routes of access to the interior from the Black sea. The chief passes on this side are those from Samsun to Amasya (Amasia), from Sinop to Ankara and from Trabzon (Trebizond) to Gumusane and beyond.

3. **Climate.**—Being cut off by peripheral mountains from the tempering influence of the sea, the central plateau experiences great extremes of heat and cold. Snow may lie there for three or four months of the winter, while in midsummer the heat and drought are extreme. High winds are common at all seasons, but they are usually dry and most of the rain is caused by local convection currents in the spring and early summer. In all these respects the Anatolian plateau resembles the steppes of central Asia and in both cases these special conditions of climate account for the generally treeless landscape.

The winds which blow outward from the cold air mass of the plateau in winter are heated by their descent to the coasts, so that in Cilicia in particular average winter temperatures are mild and snow is almost unknown. Nevertheless, winter conditions are precarious there and a sudden severe frost may ruin the whole orange crop. The eastern part of the north coast has milder winters than the western since it is sheltered in some degree by the Caucasus ranges from the winds from the Russian steppes. Consequently, the olive only thrives along this coast to the east of Sinop.

Eastward-moving cyclonic storms bring winter rains to all the coastlands and particularly to the west coast and valleys, but these storms are deflected from the central plateau by the mass of heavy cold air which settles over it in the winter. As a result, there is very little fall of rain or snow in the interior at this season and even the convectional rains of spring are slight and unreliable. All important settlements keep to the outer fringes of the plateau where springs fed by snow-melt waters from the mountain ranges produce local oasis conditions.

In midsummer, as usual in Mediterranean countries, drought settles over the whole land, including the coasts. The single exception is the north coast, especially in its eastern section, where the normally dry southward-blowing winds, having collected some moisture by evaporation during their crossing of the Black sea, meet the Pontic ranges obliquely and release a considerable rainfall. These ranges therefore, at least on their northward slopes, receive rain in both summer and winter, and this accounts for their luxuriant vegetation. (WM. C. B.)

4. **Vegetation.**—The flora of Asia Minor is rich in species and is still incompletely known, especially in the central and eastern parts. The great east-to-west extent of the Anatolian peninsula has to be borne in mind as it makes Asia Minor the most important existing route for the migration of plants, other than boreal ones, from Asia into Europe and from southern Europe into Asia.

The natural vegetation, the distribution of which is obviously mainly controlled by climatic conditions, is varied and ranges from evergreen forests and brushwoods, through deciduous woods of oaks, oriental beech and Spanish chestnut, to steppe and even almost desert communities. Both the flora and the vegetation become less Mediterranean and more Iranian the farther east and the farther inland one goes and, to a certain extent, the higher the altitude one reaches.

In conformity with the climate, the western and southern margins of Asia Minor have a Mediterranean flora and the climax vegetation is largely composed of evergreen woody communities of pines (*Pinus halepensis* subsp. *brutia* and *P. pinea*) and of maquis which by cutting, grazing and burning have often degenerated into low kermes oak scrub (phrygana). There are many bulbous plants and a wide range of shrubs, climbing plants (such as smilax and Etruscan honeysuckle) and annual and perennial herbs. Farther inland and at higher altitudes, woods of oak (various species of *Quercus*), Spanish chestnut and black pine occur. The higher peaks and chains rise above the forest limit and have a vegetation of dwarf shrubs (barberry, junipers, brooms, astragali, etc.), open scree communities and rock plants.

The northern part of the peninsula, bordering the Black sea, has what is basically a Mediterranean plant cover, but with increasing modification from west to east and at higher altitudes. In the west, maquis of evergreen shrubs, with the strawberry tree, laurel, myrtle and tree heath, are characteristic. The occurrence of *Rhododendron ponticum* and *Fagus orientalis*, even in Bithynia, strikes a distinct note. Eastward, more and more Colchic-Caucasian species are found and some Mediterranean plants (as the strawberry tree) die out.

The eastern high mountains are said to have a rather poor flora, but large areas are still not fully explored botanically. The severe winter climate, the rather low rainfall and often shallow soils result in the dominance of steppe communities. Characteristic genera include *Stipa* and *Aristida* (grasses), *Astragalus* (milk vetches in numerous species, many of which form spiny cushions), *Alhagi* (camel's-thorn), *Artemisia* (wormwoods), *Euphorbia* (spurges), *Berberis* (barberry), *Achillea* (milfoils), *Verbascum* (mulleins) and *Epilobium* (willow herbs).

The high plateau of central Asia Minor has a continental type of climate with hot dry summers and cold winters. The flora is probably richer than is at present known but the vegetation, over much of the area, consists of treeless steppes. Trees are found in some valleys and other favoured habitats and include junipers, almonds, oaks, nettle trees and wild pears. In the steppes there are many tufted grasses (*Stipa, Andropogon, Bromus*, etc.), plants with bulbs or corms (*Ornithogalum, Muscari, Gagea, Crocus*, etc.), spring flowering annuals and perennial herbs. Where the surface waters are saline, a salt-marsh flora appears, dominated by members of the goosefoot family. (W. B. T.)

5. **Animal Life.**—The animals of the western and southern parts of the Anatolian peninsula clearly belong to the Mediterranean fauna, while those of the eastern and central parts belong to

the Irano-Turanian (Asiatic steppe) fauna. In the Pontic mountains of the north, the Euro-Siberian element shows a strong penetration, and at the eastern edge certain peculiarities are found, such as melanism (especially in rodents), the presence of very peculiar mollusks and of the Caucasian salamander (*Martensiella*), and the survival of the Colchian pheasant. In the dry mountains of the south and southeast, southern elements like the Israeli gazelle (in the steppes), the striped hyena (in the mountains) and the monitor, a giant lizard, are seen. Typical of the high plateau of central Asia Minor and its eastern mountains are at least two mole rats (the European mole being restricted to European Turkey). Genera like the ground squirrel *Citellus*, the jerboa *Allactaga*, the steppe marten *Vormela*, as well as species of hare, fox and hedgehog are all Irano-Turanian steppe animals. The Moroccan locust is a permanent inhabitant of these steppes, but outbreaks only occur along the Mediterranean borders, where there are extreme fluctuations in rainfall. (*See* LOCUST.)

In the Mediterranean mountains, including those of the Pontic ranges and of the Taurus, live red and roe deer, the brown bear (with the Syrian bear in the southeastern mountains), mouflon, wild goat, and the ibex, lynx, wildcat and, rarely, leopard. Wolf, jackal, boar, badger, marten and otter occur everywhere.

Among domestic animals, the small stature of the cattle is noticeable. These beasts are almost entirely used for plowing and for transport, rarely for milk which is mainly obtained from sheep and goats. All Anatolian sheep, most of which belong to the Karaman race, are fat-tailed, with the tail ending in a thin appendix. The wool of the Angora goat of the high plateau is famous. Heavy buffaloes are kept mainly in the northwest.

The Anatolian horse is hardy and well adapted to the mountains. Hybrids of dromedaries and Bactrian camels are used for transport and in late winter, which is the rutting season, they are also used for camel fights. Pariah dogs still occur in the plains, while the dogs of mountains and high plateau are wolflike, yellowish, half-wild sheep dogs, much resembling the Molossian dogs of antiquity.

Cats are rare, but the true Angora cat excels by its long silky fur.

The birds of the Mediterranean areas show no peculiarities. In the high plateau and mountains, steppe and rock partridges abound, the francolin and two bustards are not uncommon. Colonies of the beautiful pink flamingo breed in a small lake near the salt lake Tuz Golu. Storks, both white and black, are common breeders. More common birds of prey are the bigger and lesser kestrels, griffon vulture, Egyptian vulture, golden eagle, honey buzzard, long-eared owl and eagle owl.

The only poisonous snake of general distribution in Asia Minor is the Aegean viper (*Vipera xanthina*). Other common snakes are a rat snake (*Coluber asianus*), the ring snake and five species of chicken snake (*Elaphe*). Among the abundance of fishes may be mentioned a rather common trout, barbels and *Varicorhinus; Nemachilus* and *Silurus glanis* are bottom fishes. The rich fauna of the upper Euphrates and of the Tigris is still little known.

The invertebrates are chiefly notable for the giant earthworm, found close to rivulets, and the abundance of big leeches which during the 18th and early 19th centuries were exported in quantity to Europe. Snails in the high plateau include the big *Helix lucorum, Helicella derbetina* and *Theba schuberti*. Conspicuous species of insects are the big bluish-black carabid beetles (*Calosoma*) and the big plump crickets (*Bradyporus*). The numerous butterflies in the mountains include *Parnassius apollo, P. mnemosyne* and *Doritis apollinus*. At Bursa (Brusa) silkworm breeding is still carried on by a special research institute and school. Everywhere bees are kept in primitive plaited or wooden hives. The variations of the honeybee (*Apis mellifica*) reflect the general zoogeographical character of the Anatolian fauna, for the Caucasian variety, *A. m. caucasica*, is found in the northeastern mountains, the Irano-Turanian variety, *A. m. remipes*, in the high plateau and the eastern Mediterranean variety, *A. m. syriaca*, in the Mediterranean areas which also show, near Istanbul, transitional variations between *A. m. syriaca* and the western Mediterranean *A. m. ligustica*. (F. S. BR.)

II. ETHNOLOGY

The Anatolian peninsula, being constricted between the Black sea and the Mediterranean, forms an obvious land link between southeast Europe and the countries of southern Asia, and was used as such by migratory plant and animal species as well as human races. At the same time the country has provided a retreat for specimens of these migrant populations, and the large total of its botanical and zoological species is matched by the wide variety of its racial strains.

The ethnic map of Asia Minor, therefore, is very complicated. Even as early as the 1st century A.D., Strabo (xii, viii, 1–4), in attempting to describe the peoples of Mysia and Phrygia, was perplexed by "the confusion which has existed among the nations in this district" with their many different fables of origin. Indeed, he quotes a proverb about the difficulty "of assigning the confines of the Mysians and Phrygians."

Since that time, the situation has been made still more involved by further waves of migration, notably those of the Turkish tribes in the 11th century. Moreover, the Ottoman administration aided the mixing of population. For every millet or community was traditionally expected to ply a particular craft or profession, as the Greeks their trading and the Armenians their architecture. They had cultural and religious freedom, but not territorial autonomy, and were deliberately encouraged to spread into every part of the empire.

1. Racial Prehistory.—After 1930, excavations on the plateau provided enough evidence to disprove the once popular hypothesis that the aboriginal population of Asia Minor was broad-headed, particularly of that specialized variety known as Armenoid, with a prominent nose and high back to the head. On the contrary of 32 individuals whose remains were found in Chalcolithic and Copper Age (that is, roughly, 3rd millennium B.C.) deposits in various parts of the plateau, no less than 27 were found to be long- or medium-headed. Of these, the majority were of small build with light brow ridges and thus belonged to the gracile variety of the Mediterranean race rather than to the more robust Eurafrican variety which predominated in early Mesopotamia.

In the early part of the 2nd millennium B.C., to judge from the human remains from Bronze Age strata at Alisar, Kusura, Arslan Tepe and Hisarlik, the proportion of broad-headed individuals in the population increased very quickly from about 16% in the earlier period to 42% in the later. This sudden change can only be the result of immigration and it coincides significantly with the emergence of Hittite power in Anatolia. The Hittite aristocracy probably entered Asia Minor from the east, like the Turks much later, possibly from eastern Persia or the region of the Pamirs where the population, particularly among the Tajiks, is still generally broad-headed.

These broad skulls of the early Bronze Age in Anatolia are of Alpine type, not Armenoid; that is, they are only moderately broad and show no flattening of the back of the head. This brings up the question of the origin of the Armenoid physical type, which F. von Luschan in 1911 argued to be indigenous to the plateau of Asia Minor. His thesis was based on two main observations: first that the scattered outcaste tribes, like the Tahtaci, Kizilbash, Yezidi and Druze, who live in mountainous refuges in Anatolia and Syria and whose culture proves them to be survivors of a very early population, show these Armenoid features in a very pure and extreme form; and second, that the profiles of the figures on Hittite sculptured reliefs—the only direct evidence available at the time of the physical type of the early population—are also manifestly Armenoid.

It is now clear, as has just been described, that not only was the aboriginal population of Anatolia not Armenoid, but not even the invading Hittites belonged to this race. However, the evidence adduced by Von Luschan can be reconciled with these new discoveries, thanks to what is now known about the evolution of the Armenoid physical type. This is, in fact, a hybrid, the outcome of the mixing of Alpine and Mediterranean stocks in a population, and it retains in an exaggerated form features derived from both of its progenitors. To the Mediterranean side of its ancestry may be traced the long face, close-positioned eyes and sel-

back ears, while on the other hand the sallow complexion, prominent nose and high short head clearly come from the Alpine stock. Obviously, this hybrid type may be evolved quite separately and independently in different regions where similar conditions of mixing occur. The so-called Dinaric race of the Balkans, for example, is very similar to the Armenoid, the main differences between them being the result of special features of the local variety of the Mediterranean stock to which they trace part of their ancestry.

The arrival of the Hittites of Alpine race among the aboriginal Mediterranean population of Anatolia would thus create just the right conditions for the breeding of a hybrid Armenoid race. The discrepancy between the evidence of the 2nd-millennium skulls, which are Alpine, and of the sculptured reliefs, which show Armenoid features, is explicable by their difference of date; the skulls so far investigated are nearly all early Hittite, of a time previous to extensive mixing of the populations, while the reliefs are almost without exception neo-Hittite, that is, about 1,000 years later, by which time the hybrid race had had time to develop.

Once established, the Armenoid race appears to be very persistent and, among heterodox sects of both Christianity and Islam who live and breed in conditions of extreme geographical and social isolation in remote highland regions, it has for long remained pure and resisted dilution with immigrant strains. Instances are the Kizilbash of Cappadocia, the Tahtaci of Lycia and the Armenians about Lake Van.

2. Racial Movements in Historic Times.—In the last millennium B.C., the country was invaded, and in some cases colonized, from various directions, as by the Phrygians from Thrace, the Cimmerians from across the Caucasus, the Gauls from the Balkans, and by the Jewish, Greek and other settlers brought into the cities newly founded by Alexander the Great and his successors. It would, however, be a difficult task to find any trace of the culture and still more of the physical type of these various incursors. Each in turn appears to have imposed its language and, to a less extent, its institutions, on at least a part of the country, but ultimately to have accepted the way of life native to the land and to have lost its physical identity through interbreeding.

The course of the last great migration into Asia Minor, that of the Turks in the 11th century A.D., may serve as an illustration of what, in outline at least, had happened many times before. After the initial conquest they insisted, in the regions where they settled, on the adoption of the Turkish language and on at least nominal capitulation to Islam. This much was conceded, but at the same time Turkish Islam adopted many local customs and took on a very "Anatolian" aspect, which it still retains. The Turks for the most part settled and intermarried with the indigenous population, learning from them the arts and crafts of village life and looking down on those tribes, whom they called "Turkmen," who refused to settle and kept their traditional nomadic habits in some mountain districts.

An important section of the population of the north and west coasts and of the southern portion of the plateau retained its Greek language and Christianity until the early years of the 20th century, when it was being rapidly reinforced by immigration from across the Aegean. In the early 1920s, however, most of these people were transferred to Greece under an agreement for the exchange of population by which about 1,500,000 Greeks and Armenians left Turkey and 400,000 Turks arrived there from Greece. Later, many more Turks returned to Anatolia from the Balkans, particularly from Bulgaria, which sent back 50,000 in 1950 alone.

At mid-20th century the largest minority in Turkey speaking a foreign language was that of the Kurds (*q.v.*). They are a tall, aquiline-featured people, with long and high heads, and include a large proportion of fair individuals. They are undoubtedly an intrusive Nordic stock, akin to one racial strain in the Iranian population, and speak an Indo-European language very like Persian. They live mostly east of the Euphrates, however, and are found only in eastern Asia Minor in the Anti-Taurus. They are often noticed among the mixed population of cosmopolitan Istanbul, where they come regularly to act as porters. *See* also TURKMEN; TURKIC PEOPLES; TURKEY: *The People and Population.*

III. ARCHAEOLOGY

Many different kinds of evidence must be taken into account in studying the archaeology of Asia Minor, including that of architectural remains, rock reliefs, inscriptions, burials and even of casual finds of pottery and stone implements. The most important sources of information are, however, stratified excavations, and this account will pay special regard to such work undertaken after 1930. An attempt will be made to show what are the main outstanding problems of Anatolian archaeology and what progress has been made toward their solution.

1. Stone Age.—Thanks largely to the intensive work of Sevket Aziz Kansu and his assistants at the University of Ankara, the range and variety of the Stone Age cultures of Turkey have now been thoroughly explored and a beginning has been made on the task of preparing their detailed stratigraphy.

Abbevillian (formerly called Chellean) hand axes were found on the surface of the ground near both Istanbul and Ankara, while a hand axe of Acheulean type was discovered at Tekkekoy near Samsun and some pieces belonging to the Micoquian (Upper Acheulean) industry were excavated in 1937 in the terraces of the Cubuk Suyu (stream) at Etiyokusu near Ankara, 3.1 m. (10.168 ft.) below ground level.

Specimens of the Levalloiso-Mousterian industry were excavated from the Pleistocene terraces of the Cubuk Suyu at Etiyokusu and at other places in the neighbourhood of Ankara. Further samples of the same industry were found at Golkoy near Kastamonu (Kastamuni), at Gemerek near Sivas, and near Nevsehir and Nigde in the southern part of the plateau. Tools of Mousterian type were discovered at Adiyaman near Malatya, in the valley of Tekkekoy near Samsun and in the Karain cave at the village of Yagcakoy near Antalya.

Of the classic Upper Paleolithic industries, the Solutrean and Magdalenian are unknown in Asia Minor. Tools of Aurignacian type were, however, discovered at Adiyaman in the Anti-Taurus, near some rock engravings of wild mountain goats, which probably belong to the same period. Artifacts belonging to the Aurignacian industry were taken from a stratified cave deposit near Bozanonu in the district of Isparta.

Flints characteristic of the Mesolithic period are recorded from excavations in caves and mounds near Samsun on the north coast and also from an occupation deposit at Baladiz near Isparta, while the lower strata of the mound of Pilir in the lake of Hafik, about 20 mi. N.E. of Sivas, have produced traces of wooden shafts and miniature flint blades of Campignian type. The transition from Mesolithic to Neolithic cultures may have been found by 1959 in the rock shelter of Beldibi near Antalya, which is remarkable also for its wall paintings of goats and ibexes.

2. Comparative Stratigraphy.—The main deep excavations on the plateau of Asia Minor are those of the Chicago expedition to Alisar, of the Turkish Historical society at Alaca Huyuk (hill) and of the British parties at Kusura and Beycesultan, while further information was obtained in 1950 from the deep sounding at Polatli, undertaken by a joint Anglo-Turkish party. The combined evidence from all these places made clear the sequence of cultures on the plateau which may be compared with those revealed at Hisarlik in the northwest and Mersin in the southeast. Hisarlik, the city mound of Troy (*q.v.*), is intermediate between the plateau of Asia Minor and the islands and shores of the Aegean, while Mersin, with the nearby site of Tarsus, provides a link with Syria and Iraq.

The first conclusion to be drawn from a study of the excavations on the plateau is that this region has generally remained culturally separate from the neighbouring areas to east and west.

Second, it is now clear that the civilization of the plateau has developed along a steady course and that despite the entry of alien painted ceramic styles in the early Bronze Age, Asia Minor remained generally faithful, from the earliest Neolithic times until the collapse of the Hittite empire, to a tradition of using monochrome pottery.

Third, by 1960 J. Mellaart had shown that an exception must be made of the southwestern corner of the plateau. There at Hacilar the painted-ware Chalcolithic culture of north Syria intruded.

3. Chalcolithic Period (Before c. 2600 B.C.).—At mid-20th century, the oldest pottery on the plateau (except in the southwest) could not be dated earlier than about 3000 B.C. As its name implies, it is already found in association with copper as well as stone tools. This Chalcolithic pottery usually has a black and burnished surface, generally plain but occasionally ornamented with rectangular incised patterns accentuated with a chalky filling, or still more rarely with similar designs in loose white paint. Simple dishes and open bowls were the most common vessels at this stage, but sometimes elegant pedestaled shapes were thrown, like the "fruit stands" of Level O at Alisar (*see* diagram). By the Aegean seaboard, in the lowest levels at Hisarlik and the neighbouring sites of Yortan and Thermi, the same white-filled incisions occur, but the vessels are of different shapes, handled jugs and basins with sagging bellies, modeled on leather prototypes, being very characteristic.

In view of its style and date, this Chalcolithic pottery of the plateau must be compared with the white-on-black ware of Level XII A at Mersin, which introduces half a millennium during which the Cilician plain was engulfed by the culture of the plateau. For at least 1,000 years before this, however, Cilicia had a civilization characterized by painted pottery of styles which can be matched in Syria, Iraq, Armenia, Iran and Turkistan, but not in Asia Minor, from where, except near Burdur and Konya, the painted-ware cultures were rigorously excluded by the barrier of the Taurus range.

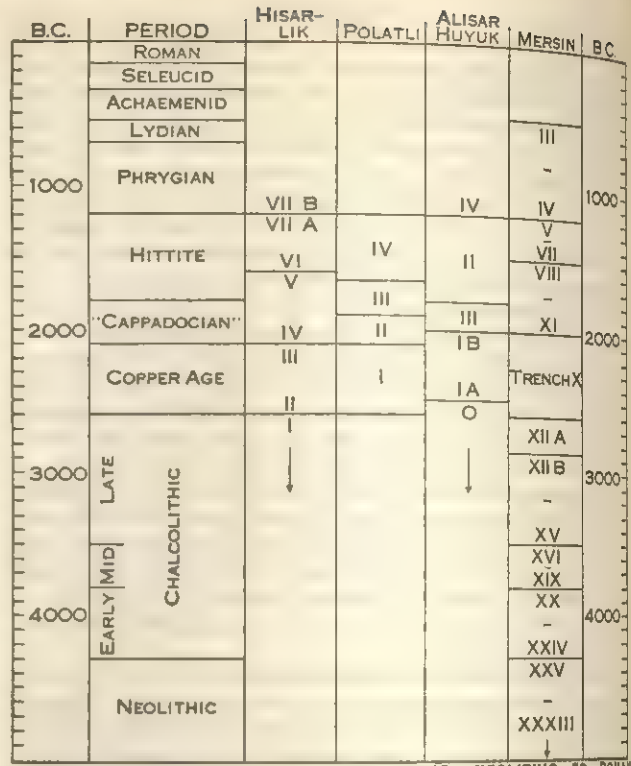
The problem therefore arises of what culture, if any, flourished on the northern and central parts of the plateau in the painted-pottery era of Cilicia and Syria. None of the relevant excavations go deep enough to answer this question with certainty. However, the pottery of the lowest Chalcolithic levels in this region is by no means primitive and there must lie behind it a long history of slow evolution, the early stages of which may be illustrated in the Neolithic levels of Cilician and northern Syrian sites. For at Mersin, Jubayl, Tell Halaf and Ras Shamra, as well as farther afield at Knossos (Cnossus) and Nineveh, the Chalcolithic painted-ware levels are underlain by Neolithic strata with a distinct style of monochrome pottery whose burnished finish and incised ornament foreshadow the traditional style of the plateau Chalcolithic wares. The shapes of the pots, however, are naturally less ambitious at this early stage.

At Mersin, the burnished and incised monochrome pottery of the Neolithic period was almost entirely replaced by the painted wares which first occur, in a crude style, at Level XXIV. Throughout the Chalcolithic millennium, however, specimens of the early monochrome pottery keep appearing and these are so different in shape and ornament from the contemporary painted wares that they are almost certainly imports from another region.

After Level XII B the painted pottery disappears as suddenly as it came in and is replaced in the succeeding Level XII A and Trench X by monochrome burnished wares of shape and decoration which can be paralleled in the earliest Chalcolithic strata known on the northern plateau. It must be assumed, therefore, that somewhere in Asia Minor the culture represented by the monochrome burnished and incised pottery, which was very widespread throughout the near east in Neolithic times, survived and developed during the 1,000 years when it was replaced in Syria and neighbouring countries by the painted-ware civilization. The place of this survival has yet to be discovered, but surface explorations point to the high basins of the Anti-Taurus, such as the plain of Elbistan, as a likely region.

4. Copper Age (c. 2500–2000 B.C.).—During the Copper Age the culture of the whole plateau of Asia Minor was probably more uniform than at any time before or since. Moreover, it was at this period that the civilization of the plateau spread for the first time far outside Asia Minor and influenced an area comparable in extent with that of the Hittite, or even of the Ottoman, empire.

The pottery styles of the Copper Age of Asia Minor develop naturally from those of the preceding Chalcolithic period. The same predilection for single-coloured burnished wares, with incised or occasionally molded ornament, continues, but some very characteristic shapes now occur which serve to identify this culture



COMPARATIVE STRATIGRAPHY OF ASIA MINOR, NEOLITHIC TO ROMAN PERIODS

with ease and certainty. Such are the broad-bellied jug, often with ornamental knobs, the shallow saucer with high vertical handle, and above all the elegant two-handled cup, probably modeled on a metal prototype and identified with the Homeric *depas amphikypellon* (*Odyssey*, iii, 40–63).

This plateau culture is clearly intrusive at Mersin in the disturbed strata of Trench X, corresponding with Period A at Tarsus, and also on the Amuq plain near Antioch in Judeideh XI and Tabara el Akrad IV. In these last two instances, the style of pottery whose arrival marks the change is the Khirbet Kerak ware, named after one of the sites in Palestine where it also appears suddenly about 2600 B.C. and remains in use for two centuries. This Khirbet Kerak ware is characteristically Anatolian, but is distinguished by its ornament of ribs and flutings and of raised geometrical patterns, especially spirals, as well as by its bold use of contrasting colours, the insides of many of the vessels being brilliant red, by contrast with their outsides which are black. This effect is produced by careful control of the conditions of firing and is an art which was used commonly in the Copper Age in Asia Minor, but with special skill in the upper Euphrates and in the Kura-Aras valleys of the Caucasus, from where the southward invasion of the makers of the Khirbet Kerak ware seems to have stemmed. Sir Charles Leonard Woolley (*A Forgotten Kingdom*, pp. 33–35, 1953) identifies these invaders as the early Palestinian Hittites, who are referred to in several contexts in the Old Testament, such as Numbers xiii, 29 and Genesis xxiii. He suggests further that Hittite power was established in Asia Minor by a branch of this invasion which moved westward and then northward from Syria and through Cilicia.

Approximately at the same time as this Khirbet Kerak invasion of Syria and Palestine from the north, typical Anatolian Copper Age pottery suddenly entered the southern Balkans, with the Early Helladic cultures. In Greece, as in Syria and Cilicia, the Anatolian type of pottery overlies earlier painted wares, of the Sesklo and Dimini styles, which are indeed so like those of the Syrian Chalcolithic that they must be presumed to be derived from that source. The link was probably by sea, though Chalcolithic painted shards found near Konya and Afyonkarahisar give a clue that the land route across the south of the plateau from Cilicia to the Aegean was already in use.

The most remarkable relics of the Anatolian Copper Age are the

royal tombs of Alaca Huyuk, which lay below the level of Hittite occupation and were sealed from it by a deep "destruction" layer of ashes. There were 13 rich tombs, dated by the Turkish excavators from their stratification and the style of the included pottery to the period of approximately 2500–2300 B.C.

5. Early Bronze Age or "Cappadocian" Painted-Ware Period (*c.* 2100–1850 B.C.).—The earliest written records found in Asia Minor are the clay tablets which were recorded from Cappadocia in 1882 but which were first carefully collected by the famous expedition of Ernest Chantre in 1893–94. Since 1948 the excavations of T. Özgüc at Kultepe illuminated the culture in which these records occur. The tablets themselves are mostly business letters, but also legal documents and accounts, belonging to a colony of Assyrian merchants.

It happens that the establishment of this commercial link with Assyria coincides closely with the appearance on the plateau of a quite new and distinctive type of polychrome painted pottery, the so-called "Cappadocian" ware. Some features of this new painted style, such as the "hawk eye" pattern on the spouts of painted jugs, can be matched in northern Syria, as would be expected in view of the southward trading contacts of Kultepe at the time; but in its general patterns, shapes and colours this pottery is quite distinctive and bears all the signs of having been introduced into Anatolia by new settlers. Moreover, from the distribution of their pottery, it seems that these immigrants must have come in from the east rather than the west, for Cappadocian ware is found only very sporadically west of the Kizil Irmak, but it has already been traced as far east as Lake Urmia in Azerbaijan, Iran, where it occurred in quantities in Period D at Geoy Tepe. (T. Burton-Brown, *Excavations in Azerbaijan, 1948,* 1951.)

From the evidence of language and physical anthropology, the Hittite peoples appear to have entered the plateau from the east at about the same time and it seems therefore reasonable to recognize in them the bearers of the Cappadocian painted-ware culture. Against this assumption must be reckoned the eclipse of the painted wares when the Hittite empire first took shape in the 18th century B.C. Nevertheless, it is quite conceivable that those who introduced this Cappadocian pottery were in fact proto-Hittite invaders and that, having arrived on the plateau, they quickly came to terms with the indigenous inhabitants whom they found there and took over and developed many features of the native civilization including its style of pottery. In later times the successive invasions of the Phrygians, Gauls and Turks, for example, followed a course very like this.

6. Imperial Hittite Period (*c.* 1850–1200 B.C.).—Asia Minor now enters the full historic era, and the evidence of archaeology becomes supplementary to that of documents. In both texture and ornament, the pottery of this period follows the monochrome tradition of the Copper Age, but the invention of the potter's wheel makes possible the manufacture of vessels of more elegant and ambitious shapes, like the long-spouted jars (Schnabelkannen), some of which were evolved from prototypes of the Cappadocian period.

The Hittite empire was centred on the plateau, but was not so preponderant on the coasts, which seem at this period to have been generally under Mycenaean influence, as shown for example by the pottery of Level VI at Hisarlik. The Mycenaean civilization, which probably corresponds to that of the Achaeans of Greek tradition, did not belong to a centralized empire like the Hittite but rather to a loose confederacy of sea-trading communities which controlled many of the shores of the eastern Mediterranean from the 15th to the 13th century B.C. (*See* AEGEAN CIVILIZATION.) The type and degree of contact between the Hittite and Mycenaean civilizations are not yet clear. In his *Ionia and the East* (1909), D. G. Hogarth argued that along the central Aegean frontage of Asia Minor, the region which later became Ionia, the Hittite power penetrated to the coast and excluded the Mycenaean. Certainly some of the rock reliefs of Hittite style near Smyrna would seem to point to this conclusion; yet excavations at Old Smyrna have not yet revealed a Hittite stratum. The Middle Bronze Age city uncovered by Seton Lloyd at Beycesultan on the upper Buyukmenderes was culturally distinct from its Mycenaean and Hittite neighbours, but shared some architectural features with Minoan Crete.

On the Cilician coast, however, at least one point was under Hittite control, as proved by the remains of the fortress in Levels VII–V at Mersin. There the few Mycenaean shards in Level V are a rare sign of contact between the two cultures, which seem also to have met on the plateau at the Hittite city at Fraktin, where Mycenaean pottery has been discovered. (*See* also HITTITES.)

7. Phrygian Period (*c.* 1200–700 B.C.).—About the year 1200 B.C. the Hittite empire came to a sudden end as a result of the attacks of the land and sea raiders who swept forward from beyond the Aegean, through Asia Minor and Syria, until they were held up in 1193 in Palestine by Rameses III of Egypt. The disaster is marked at Alishar Huyuk, Kultepe, Bogazkoy and Alaca Huyuk (*qq.v.*) by a great conflagration in the last Hittite level, and at Mersin and Atchana occupation ceases with equal abruptness. At Hisarlik the break comes between Cities VII A and VII B at a time which corresponds very closely with the traditional date for the fall of Troy.

The Mycenaean culture of the sea frontages suffered from the same upheaval. After a short confused period, it was replaced by new barbaric cultures, in which iron was more commonly used, button seals replaced cylinders and the naturalistic art of the Minoan-Mycenaean tradition gave place to the protogeometric pottery style, with mechanical zoned and paneled designs based on triangle, lozenge and concentric circle patterns.

Out of the chaos which followed the overthrow of the Hittite empire there emerged the Urartaean power in Armenia, the Phrygian kingdom of the western plateau and the neo-Hittite states of northern Syria and the Taurus and Anti-Taurus foothills.

These last neo-Hittite principalities used a hieroglyphic script which appears on many monumental inscriptions of southeastern Asia Minor. In 1946 at Karatepe (*q.v.*), an 8th-century B.C. fortress in a remote part of the valley of the upper Ceyhan, were found the most important of these inscriptions, for, being written alongside a Phoenician translation, they have considerably aided the decipherment of this enigmatic script. The Karatepe inscriptions record the founding of the city by a certain Azitawad, king of the Dananiyim, who lived in the plain of Adana.

The successors of the Hittites on the major part of the plateau were the Phrygians (*see* PHRYGIA) who according to Greek tradition were related to the Thracians and ultimately colonized Armenia. They spoke an Indo-European language, of the eastern branch, and doubtless included an immigrant element recently arrived from across the Bosporus; but it seems that their kingdom was peopled more by a coalition of former subjects of the Hittite empire than by its invaders. Certainly the art of the Phrygian rock monuments in the district about Gordium (*q.v.*), the capital of the kingdom, owes much to Hittite inspiration; for instance, the pairs of opposed lions rampant over the doorways of tombs.

Yet there are many features of Phrygian art and architecture which came new to Asia Minor such as the stone tumuli with corbeled burial chambers like the "Tomb of Tantalus" on the slopes of Yamanlar Dagi (Mt. Sipylus) above Izmir. Moreover, the gabled façades to the false rock-cut tombs near Gordium have no counterpart in Hittite sculpture, and the intricate geometrical patterns carved on these tomb fronts, possibly in mimicry of carpet designs, are also specifically Phrygian. This sculptured ornament recalls the friezes on the painted Phrygian pottery of a style which is quite novel in Anatolia. This pottery, with its geometrical patterns, repetitive panels, simple animal silhouettes and miniature circles multiplied to fill vacant spaces, has basically much in common with the contemporary geometric styles of the eastern Mediterranean while keeping certain features of its own.

8. Lydia, Caria, Lycia and Greek Colonies (*c.* 700–546 B.C.).—Despite the overthrow of the Phrygian empire by the invading Cimmerians in the early 7th century B.C., some offshoots of this civilization survived in the interior, as, for example, at the castle of Pazarli, dating from about 500 B.C., where Hamit Zübeyr Kosay uncovered in 1937–38, for the Turkish Historical society,

Phrygian reliefs and wall paintings of lions, bulls, deer, winged griffons, centaurs and soldiers parading with shields and spears.

Elsewhere the Phrygian power was succeeded by the various civilizations speaking Asianic languages like those of Lydia, Caria and Lycia (*qq.v.*). These peoples were of various origins, some being invaders who brought about the downfall of the Hittite realm, others relics of the old subject populations of the Hittite empire.

These indigenous civilizations of Asia Minor flourished at the same time as the Greek colonial foundations, Aeolic, Ionic and Doric, which began to be established on the Aegean shores in the 8th century B.C.; it is therefore important to know what sort and degree of contact there was between them, and in particular how much the young civilization of Ionia (*q.v.*) owed to its neighbours inland. Certainly Phrygia must have had some connection with the Greek world shortly before the collapse of the kingdom, for the alphabet of the inscriptions on the Midas tomb and other monuments is patently borrowed from the Greek. Moreover, the large cultural debt of the Ionian cities to their inland neighbour, Lydia, was proved by G. Radet (*La Lydie et le monde grec*, 1893), by Sir William M. Ramsay (*Asianic Elements in Greek Civilisation*, 1927) and by D. G. Hogarth (*Ionia and the East*, 1909). Hogarth, however, overestimated the continuity between the Hittite and early Greek civilizations, through Phrygian and Lydian intermediaries, and Ekrem Akurgal's work (*Spaethethitische Bildkunst*, 1949) has shown how long was the hiatus between the imperial Hittite and the fully developed Phrygian civilization, and how comparatively late the land routes from the Aegean to the east were reopened. It is probable that the early Greek colonists on the coasts of Cilicia and north Syria, who had close links with the neo-Hittite states of the southern Taurus and north Syria, were at least as influential as the overland traders of Ionia and Lydia in introducing the "orientalizing" features into the art of the Aegean world in the late 8th and in the 7th centuries B.C.

9. Achaemenid and Seleucid Asia Minor (546–133 B.C.).—With the conquest of Lydia by Cyrus (*q.v.*) in 546 B.C., the major part of Asia Minor again came under single control for the first time since the downfall of the Hittite empire. The old Hittite road round the north side of the central plateau, which had probably never been completely abandoned, was re-established as the royal road from Sardis in Lydia to Susa in Persia, while the great eastern trade route was opened along the southern edge of the plateau.

The Persian kings, however, did not change the civilization of Asia Minor as much as Alexander and his successors, whose policy was not to rule the country from outside but to colonize it. So, beginning in the late 4th century, a whole series of new cities was founded, usually at strategic points along the routes of trade and administration which had been re-established by the Persians. Sometimes old Anatolian religious centres, like Hierapolis, were refounded and renamed; elsewhere, completely new cities were set up, like Laodicea on the Lycus.

These foundations were profoundly different in both economy and administration from the old rural centres of Anatolia, and these differences were reflected in their architecture. The old Anatolian cities, like Pessinus, Olba and Comana of Cappadocia, had been, as Strabo's descriptions show, provincial centres with a large agricultural population subordinate to and serving the temple. They were distinguished not by their constitution but only by their size from the Anatolian villages, where the populace was divided into the same two strata of theocracy and serfs.

In the new Hellenistic cities, by contrast, a more elaborate and democratic administration was practised. The population was divided into age grades, residential tribes and trade guilds, and various paid and honorary officers supervised the work of the police, schools, markets and other municipal functions. Specialized industries were set up, trade became increasingly important and the cities ever more dependent on the highways between them.

10. Roman Rule (From 133 B.C.).—When Roman power was extended to Asia Minor, these municipalities and highways were used as bases for annexing and ruling the whole of the country. The cities became progressively larger, more luxurious and more detached from the surrounding countryside. Their great public buildings, agorae, stadia, amphitheatres, gymnasia and triumphal arches, whose ruins are today so common throughout Anatolia (*see*, for example, EPHESUS), were built on a pattern which was common throughout the Roman world. In imperial times, as these cities grew in size, increasingly elaborate aqueducts and drainage canals were needed to serve them. Justinian's trench at Edessa (*q.v.*) and the flood-diversion works of Vespasian and Titus at Seleucia Pieria are impressive monuments of the engineering skill of the age.

11. Christian Antiquities.—In many districts Christianity and paganism rose to strength alternately in accordance with the trend of official persecution or toleration. Elsewhere the two appear, from the evidence of ambiguous epitaphs, to have combined into an unstable mixture, and in these regions heresy was constantly liable to arise.

Some of the earliest Christian churches of the world lie just outside Asia Minor proper, in the districts of Urfa and Mardin, while in Anatolia most of the Christian basilicas date from the time of Justinian or later. The catacombs of the Cave of the Seven Sleepers at Ephesus and the chapels hewn from the soft volcanic rock at Bin Bir Kilise (the "Thousand and One Churches") on the slopes of Kara Dag are two remarkable Christian monuments.

12. Seljuk Conquest (A.D. 1071).—The immediate result of the Seljuk conquest of Asia Minor in the 11th century A.D. was that many of the great Hellenistic foundations became deserted. This was very rarely the result of destruction of the cities but rather of the almost accidental interruption of commerce, communications and, above all, water supply by the nomadic tribes who followed in the wake of the invading armies.

The massive walls of the *hans* or caravansaries, which are among the grandest monuments of Seljuk rule in Asia Minor, are proof of the state of insecurity which prevailed in the country in early Turkish times, the result of the depredations of the unruly nomadic tribes. Hence the Turkish towns served as local market centres rather than as emporia or administrative links on imperial highways and were obliged to be much more self-sufficient than in the former days of easy communications.

13. Asia Minor as a Link Between Europe and Asia.—The archaeology of Asia Minor illustrates the mobility of the ethnic and cultural frontier between east and west. At some periods like the Achaemenid, the boundary lay just inland from the Aegean; later, in Seleucid times, it moved temporarily eastward as far as the Punjab; while in imperial Roman times it remained static for several centuries along a defensive frontier running from the Caucasus, through Armenia, Syria and the province of Arabia to the Gulf of Aqaba. The fluctuations of this boundary help to explain the variety of the cultures which have influenced Anatolia both from the west and from the east.

At the same time, Asia Minor has kept, from the earliest period, strong individual traditions in its culture and economy and often the immigrants themselves gradually modified their habits and institutions to accord with those of the indigenous inhabitants who knew "the manner of the God of the land" (II Kings xvii, 26. Both the ethnology and archaeology of Asia Minor illustrate the vigour of the old rural civilization of Anatolia and of the native genius of the country, which has continued to assert itself despite every outward change of rule, race and religion. (WM. C. B.)

IV. HISTORY

The course of the prehistory and of the ancient history of Asia Minor is broadly outlined in the ethnological and archaeological sections of this article. An exhaustive account of the dominant power in Asia Minor in the greater part of the 2nd millennium B.C. is given in the article HITTITES. For the peoples whose invasions precipitated or exploited the decline of the Hittite kingdom, from *c.* 1200 B.C., *see* AEGEAN CIVILIZATION and PHRYGIA. The Phrygian kingdom succumbed to the invasion of the Cimmerians (*q.v.*) *c.* 700 B.C., on whose disappearance various "Asianic" civilizations rose to importance (*see* LYDIA; LYCIA; CARIA;

also MYSIA). Lydia, the most important of these, survived the invasion of Cyaxares the Mede but fell to Persia when Cyrus defeated Croesus in 546. For the Greek cities of the Aegean coast during the Persian period, *see* IONIA.

The invasion of Alexander the Great in 334 B.C. put an end to the Persian empire of the Achaemenids and brought most of Asia Minor into the Hellenistic world. The Wars of the Diadochi gave the greater part of Asia Minor to the Seleucid dynasty (*q.v.*), but the 3rd century B.C. saw also the rise of Bithynia and the incursion of the Gauls (*see* BITHYNIA; GALATIA), as well as the beginnings of the kingdom of Pergamum (*q.v.*).

The battle of Magnesia (*q.v.*) (190 B.C.) established Roman influence in the place of Seleucid; but the Roman province of Asia, of which Pergamum was the nucleus, was not formed till 133 B.C. The competition that Pontus (*q.v.*) offered to Rome in the 1st century B.C. was eliminated by the defeat of Mithradates VI.

For further details of the region's ancient history *see* CAPPADOCIA; LYCAONIA; PAMPHYLIA; PAPHLAGONIA; and PISIDIA.

The early history of the spread of Christianity in Asia Minor is familiar to readers of the Acts of the Apostles and of the Pauline epistles; a later development was Montanism. One of the pre-Christian cults is discussed under GREAT MOTHER OF THE GODS and ATTIS.

For Diana of the Ephesians *see* ARTEMIS.

When the Roman empire was divided in the 4th century A.D., Asia Minor was of course included in the Eastern or Byzantine part. The Persian armies of Khosrau II, which overran the country in the first quarter of the 7th century, were eventually expelled by Heraclius. Next, the Arab conquest of Syria exposed Byzantine Asia Minor to a new enemy whose incursions continued, with varying degrees of success, until the middle of the 10th century (*see* CALIPHATE). The 11th century, however, saw the arrival of the Seljuk Turks, the battle of Manzikert, the formation of the Lesser Armenian state of Cilicia and the beginning of the crusades. (*See* SELJUKS.) The Greek Christian empire of Trebizond (*see* TRABZON) was set up after the establishment of the Latin empire at Constantinople during the fourth crusade. After the Seljuk empire of Rum was subdued by the Mongols (1243), its vassal peoples began to assert their independence. The culmination of this process was the emergence to power of the Osmanli or Ottoman Turks. From this point the history of Asia Minor is that of Turkey (*q.v.*).

ASIANIC LANGUAGES: *see* ANATOLIAN LANGUAGES.

ASIENTO, a Spanish word meaning contract, is used in particular to designate the *Asiento de Negros* or "Asiento treaty" concluded between Great Britain and Spain in 1713. The idea of a contract for the supply of Negro slaves to Spanish America originated in the middle of the 16th century, when the Spanish monarchy found itself unable to do more than keep its colonies supplied with manufactures. *Asientos* before 1713 had been held by individual Spaniards, by Portugal and, in 1701, by France. Though heavy taxation, government interference and disturbed conditions of trade had combined to make them unprofitable, the idea of an *asiento* yet remained popular with foreigners as affording a chance to share in the trade with Spanish America and to acquire some of the bullion that it produced. Consequently the treaty signed with Great Britain on March 26, 1713, raised high hopes and constituted the solid basis for the South Sea Bubble (*q.v.*).

Essentially the treaty gave the South Sea company the right to send 4,800 Negro slaves to the Spanish colonies yearly for 30 years and permitted the dispatch of an annual ship of 500 tons to engage in general trade. The South Sea company found its *asiento* no more profitable than had earlier contractors: first, trade was considerably disturbed by war (between 1717 and 1727, for instance, the ship sailed only four times); secondly, the company was obliged to pay an annual tax of £34,000 on the first 4,000 slaves, regardless of whether they were actually imported (which, in fact, they never were). Moreover, the concession of the right to send the annual ship gave rise to a vast contraband trade which continually exacerbated relations between Great Britain and Spain, leading, in 1739, to war. This upset the profitable trade with peninsular Spain. Therefore, although Spain renewed the *asiento* at the peace of 1748, Great Britain agreed, in a new commercial treaty of 1750, to relinquish its rights in return for a payment from Spain of £100,000.

See J. O. McLachlan, *Trade and Peace with Old Spain, 1667–1750* (1940). (B. J. R.)

"AS IF," PHILOSOPHY OF, the English version of the name given by the German philosopher Hans Vaihinger (1852–1933) to the system expounded in his book *Die Philosophie des Als Ob* (1911; English trans. by C. K. Ogden, *The Philosophy of As If*, 1924). The distinctive feature of this work is its account of "fictions." These fictions are held to be the constituent elements of all human knowledge, whereby the will, in its effort to come to terms with irrational and unknowable reality, constructs rational explanations of phenomena "as if" there really were knowable grounds for believing them to be true in the sense of conforming to reality. The value of these fictions (which are not to be confused with hypotheses, verification of which would be assumed to be possible) consists only in their satisfying the practical purpose of the will to fabricate a habitable universe. For this purpose, Vaihinger maintained, it did not matter if they were recognized as involving ultimate logical contradictions. Fictions must provide all man's science and the foundation of all ethical behaviour and of all religious belief. Man must make up his physics "as if" such concepts as force and matter corresponded to a physical reality, his morality "as if" ethical certainty were possible, his theology "as if" there were a God.

Vaihinger's philosophy, which he himself described as based on "idealist positivism" or "positivist idealism," owes much to the immediate influence of Arthur Schopenhauer and F. A. Lange. Ultimately it takes as its point of departure the Kantian distinction between the phenomenon, to which knowledge is confined, and the "thing in itself," or unknowable reality (*see* KANT, IMMANUEL). It is interesting as a development of Kantianism in the direction of pragmatism (*q.v.*)—a move made by Vaihinger quite independently of contemporary U.S. philosophers.

ASIR ('ASIR), the southwestern province of Saudi Arabia, consists of three parts: a coastal plain, a belt of high mountains with a highest peak of 9,400 ft., and the upper Bishah and Tathlith valleys, both of which rise in its highlands. Area 40,130 sq.mi., pop. about 1,000,000. The capitals of the three sections are Qizan (Jizan), the principal Red sea port, Abha (7,150 ft.) and Khamis Mushayt, respectively. The southern boundary, from a

point on the coast 40 mi. S. of Qizan to the edge of the Empty Quarter (Rub' al Khali) (and including the administratively separate province of Najran), was agreed between the Saudi and Yemen governments in the treaty of Taif (May 1934), being later (1935–36) demarcated and mapped in detail. The northern boundary runs roughly along 18° N. lat. from the small port of Al Qahmah to Abha and Khamis Mushayt, whence it goes northeast to Al Kahfah in the Tathlith valley. Some of the finest mountain scenery of the kingdom is in this province, as at Fayfa', a fine 7,000-ft. peak, terraced up to its summit with varied cultivation, including coffee, indigo, ginger and *Catha*. Geographically the province forms a northern extension of Yemen, whose mild climate and relatively generous rainfall it largely shares.

Under the aegis of the Abbasid caliphs of Baghdad, Asir long constituted the Mikhlaf Sulaimani of the Zaidi rulers of Yemen, who derived a large revenue from its agricultural prosperity, which the Saudi government has planned to revive. In the 13th century its capital, Quhaifa, on the banks of the Wadi Qizan, was reputed to have had 500 sesame oil presses. The principal mosque of Abu'Arish, built in the 17th century by an ancestor of the imams of Yemen, is in ruins; but the surviving 18th-century mosque of the Ashraf commemorates a revolt against Zaidi rule by a local *sharif*, who made the town his capital (of Asir Tihamah). His successors maintained their position until 1872 when, after the opening of the Suez canal (1869), the Turks occupied Asir and Yemen until World War I. Ahmad ibn Idris al-Idrisi, a sharif from Morocco, founded in the early 19th century at As Sabya, 22 mi. N. of Qizan, the Idrisiyya religious order, and the hamlet developed into a considerable township of his devotees. He died there in 1837. Neither he, however, nor his son and grandson who succeeded to his spiritual mantle showed any sign of coveting temporal power, living peaceably under the Ashraf and Turkish regimes until about 1909 when the Young Turks sought to replace the prevailing *Shari'a* law by their secular codes. This produced revolt, before which the Turks withdrew, leaving the field open to Ahmad's great-grandson, Mohammed al-Idrisi, who proclaimed himself ruler of Asir Tihamah. During World War I he sided with the British against Turkey, and was rewarded with the gift of the Yemen Tihamah down to Al Hudaydah inclusive in 1921, though the imam Yahya recovered this slice of territory in 1925. Mohammed died in 1923 and was succeeded by his inexperienced son 'Ali, who was deposed in favour of his uncle Hasan by Ibn Sa'ud in 1926 on his proclamation of a protectorate over Asir. Meanwhile, in 1920, Ibn Sa'ud had wrested the highland and eastern sections of Asir from the Ibn 'Aidh dynasty of Abha; and in 1930 the process of absorption of the province into his realm was completed by the abolition of the protectorate and the establishment of regular administration.

Apart from agriculture, the economy of Asir is supported by a mine of rock salt at Qizan, while the Farasan Islands, 10 mi. offshore, consist largely of salt domes. Several efforts to prospect for oil in the latter proved unsuccessful. Cattle, sheep, goats and camels are widely raised throughout the province.

See H. St. J. B. Philby, *Arabian Highlands* (1952).
(H. St. J. B. P.)

'ASKARI, JA'FAR AL- (1887–1936), Iraqi statesman, a devoted servant of the kingdom of Iraq from its creation in 1921, was born in Baghdad in 1887, educated locally and in Istanbul and commissioned in the Turkish army in 1909. A burly, attractive figure and an accomplished linguist, he gave proof of excellent abilities and of outstanding moral and social qualities. Sent in 1915 to join Turkish forces in Cyrenaica during World War I, he was wounded and taken to Cairo as a prisoner by the British and, after an attempted escape, joined the Arab rebel movement against the Turks (1916), together with Nuri as-Sa'id (*q.v.*), his brother-in-law and lifelong close associate. In the Hejaz and later Syrian campaign of 1916–18 he rendered valuable services as the amir Faisal's chief of staff and army commander, and during 1918–20 he served as Faisal's governor of Aleppo and in other posts. Moving to Iraq, he became, under the high commissioner Sir Percy Cox (*q.v.*), defense minister in the first Iraqi cabinet, a creator of the Iraqi army and, from Aug. 1921, a pillar of the new monarchy. Thereafter until his murder by insurgent troops at Baghdad on Oct. 30, 1936, he was repeatedly minister, prime minister and Iraqi ambassador in London, contributing greatly to Iraqi progress and stability.

See S. H. Longrigg, *Iraq, 1900 to 1950* (1953).
(S. H. Lo.)

ASKE, ROBERT (1501?–1537), English country gentleman and lawyer who in 1536 led the northern insurrection called the Pilgrimage of Grace, came from an old Yorkshire family. Discontented with the policies of Henry VIII, he occupied York on Oct. 16 and five days later captured Pontefract castle from Lord Darcy of Templehurst, who with the archbishop of York then joined the rebels. Aske arranged for the monks and nuns to be reinstated and prevented the king's herald from reading to the commons a royal proclamation which had recently quieted a similar rebellion in Lincolnshire. With the banner of St. Cuthbert and the badge of the "five sacred wounds" brought by the Durham contingent, he led some 30,000 men toward London to present their grievances to the sovereign and to obtain the expulsion of low-born councilors and restitution for the church. But at Doncaster he met the duke of Norfolk who, commanding royal forces vastly inferior in numbers, tricked him into disbanding his followers on the assurance of the king's pardon and the promise of a parliament at York.

Aske then went to London under safe conduct, was well received by Henry VIII and put into writing a full account of the rising and of his share in it. Persuaded of the king's good intentions, he returned home in Jan. 1537, bringing with him Henry's promise to hold a freely elected parliament at York. Throughout prolonged negotiations he alone was responsible for keeping the rebels quiet and content to rely on Henry's word; in Jan. 1537 he assisted in pacifying Sir Francis Bigod's rising. This new rebellion, however, gave the king an excuse for breaking his promise and he sent the duke of Norfolk to Yorkshire with another army. Aske, now at last disillusioned, appears to have involved himself in technically new treasons not covered by his pardon, and on false assurances of security he was persuaded to go to London, where he was arrested in April and on May 17 was sentenced to death. He was taken back to Yorkshire on June 28, paraded through the towns and countryside and on July 12 was hanged at York, expressing his repentance for having broken the law but maintaining that both the king and Thomas Cromwell had promised him pardon.

Though little enough is known of him, it is clear that Aske possessed remarkable qualities of leadership. He gave to an expression of largely selfish discontents the spirit of a religious crusade, and his hold especially over the common people rested on his manifest sincerity. A loyalist by nature, he made an ineffectual rebel, but his fate and person dignified the Yorkshire rising and the old religion.

ASMA'I, AL- (al-Asma'i 'Abd-al-Malik ibn Quraib) (c. 740–830), Arab scholar, the greatest philologist of his age, was born in Basra and became a leading figure in the philological school there. He later became for a time tutor to the son of Harun al-Rashid in Baghdad and then retired to Basra, where he died c. 830. He was famed especially for his knowledge of ancient Arabic poetry and most of the existing collections of the works of the old poets of Arabia were compiled by him, as well as an anthology called *al-Asma 'iyyat*. Of Asma'i's many works mentioned in the *Fihrist* ("Catalogue") of the 10th-century Arabic bibliographer al-Nadim about 15 or 20 are extant, mostly in recensions made by his students. They are mainly philological monographs on the various animals, plants, customs, grammatical forms, etc., which occur in pre-Islamic Arabic poetry.

Bibliography.—The text of *al-Asma 'iyyat* was ed. by W. Ahlwardt (1902). For a life of Asma'i *see* Ibn Khallikan's biographical dictionary in Eng. trans. by M'G. de Slane, vol. ii, pp. 123–127 (1842–71). See also G. Flügel, *Die grammatischen Schulen der Araber*, pp. 72 ff (1862); C. Brockelmann, *Geschichte der arabischen Literatur*, vol. i, pp. 104–105 (1898), and *Supp.*, vol. i, pp. 163–165 (1937).

ASMARA, the capital of the state of Eritrea, northeast Africa,

formerly an Italian colony but now federated with Ethiopia, stands on the eastern edge of the Hamasen plateau at an altitude of 7,600 ft. from where a spectacular road and a mountain railway descend to the port of Massawa on the Red sea coast 40 mi. away. It has a pleasant climate, with a rainy season from June to September. The surrounding country is hilly and somewhat bare. Pop. (1956 est.) 123,083, roughly half Christian and half Muslim, with 10,000 foreign inhabitants, mainly Italians.

The town, formerly divided into European and native zones, contains well-planned streets, avenues and modern buildings, including the palace in its park, now the residence of the imperial representative, the legislative assembly building reconstructed since federation and the new municipal building. The Roman Catholic cathedral, the striking Coptic church, one of the largest of its kind, and a fine mosque were built by the Italians. There are large markets and many good shops. From the airport, 2½ mi. away, there are services to Addis Ababa and other African towns linked up with world airlines.

Until 1897 Asmara was a hamlet with no distinction save that of having been for a while in the 1880s the headquarters of Ras Alula, the viceroy of King John IV (Johannes). It became the capital of the new Italian colony of Eritrea (1900), but until 1934 was a small colonial town. It then expanded rapidly, first as the main base for the attack on Ethiopia and then as leading city in the new Italian empire. It was captured by commonwealth forces in 1941 and with the rest of the territory remained under British military administration until Nov. 1952, when, in accordance with a resolution of the United Nations, Eritrea became federated with Ethiopia. (F. E. Sd.)

ASNIÈRES, a town in north central France in the former *département* of Seine on the left bank of the Seine, 1.5 mi. N.N.W. of the fortifications of Paris of which it has become an industrial suburb. Pop. (1962) 81,747. There are the 17th-century church of St. Geneviève, an 18th-century chateau and a dogs' cemetery on an island in the Seine. The town is a boating centre for Parisians. Automobiles, medicines, margarine and perfumes are manufactured.

ASOKA, emperor of India from *c.* 274 to 232 B.C. His precise dates have been much disputed. The evidence for his reign comes both from inscriptions engraved on rocks and pillars throughout his dominions and from traditions preserved in Sanskrit literature and in the Pali chronicles of Ceylon. According to the latter he secured his throne by a wholesale massacre of his brothers, but this may be merely legendary. To the empire inherited from his father Bindusara and his grandfather Chandragupta (*q.v.*), he added the coastal province of Kalinga between the Mahanadi and the Godavari rivers. On the northwest his empire embraced the satrapies of Paropanisadae (Kabul), Aria (Herat), Arachosia (Kandahar) and parts of Gedrosia (Baluchistan), ceded to Chandragupta by Seleucus I Nicator; on the northeast his empire reached Kamarupa (Assam), and included Kashmir and Nepal and the whole of the Indian peninsula as far south as the Penner river.

Two versions of the inscriptions in the northwest (at Shahbazgarhi and Mansehra) are in the Kharosthi script, while those from the remainder of the subcontinent are in Brahmi. They are thus of great importance not only as historical documents but also as evidence for the early development of the Indo-Aryan languages and for the study of the history of writing in India. Composed in Prakrit, these inscriptions were first deciphered in modern times by James Prinsep in 1837. In addition to the inscriptions entirely Indian in language, a fragmentary inscription in Aramaic is known from near Laghman (Sanskrit, Lampaka) on the Kabul river; and in 1958 a bilingual inscription in Greek and Aramaic was discovered near Kandahar.

In the inscriptions the king is regularly named only by the royal title Piyadassi ("of benevolent aspect," Sanskrit *Priyadarsin*; the Kandahar Greek reads *Piodasses*), but his identification with the Asoka of the literary sources was confirmed by the discovery at Maski in 1915 of a version of one of the minor edicts where the name Asoka does occur. In accordance with the doctrine of *ahimsa* ("nonviolence") he suppressed the royal hunt and stressed the sanctity of animal life. One of the edicts records that Asoka became a lay Buddhist (*upasaka*), but there is no direct evidence that he entered the Buddhist order as a monk. He did, however, send out envoys and missionaries to foreign countries, and the conversion of Ceylon to Buddhism is attributed by the Pali chronicles to Asoka's son Mahinda.

In the 13th year after his coronation he instituted quinquennial circuits of officials for the purpose of proclaiming the moral law, and in the following year he appointed *dharma-mahamatras*, or censors of religion and morals. He was eulogized for his policy of religious toleration, and there is no need to doubt his sincerity; but it is also clear that his preaching was a deliberate instrument of policy.

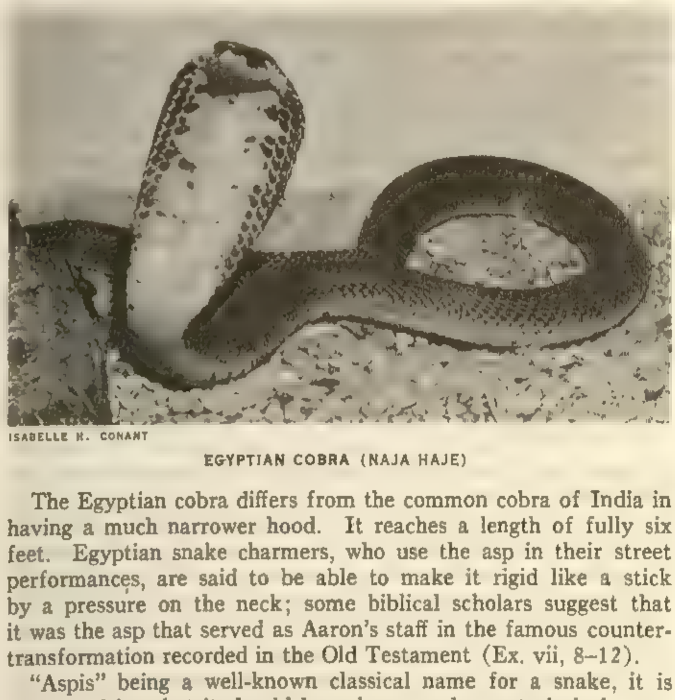
ASP, the very venomous Egyptian cobra (*Naja haje*), a snake sacred to the Egyptians and adopted as a symbol by their royalty. The asp, as the *aspis* of the Greeks and Romans, is familiar in literature; and since Galen reports the use of this species to give a merciful death, by a bite in the breast, to condemned prisoners, there seems to be no reason to search further for the identity of Cleopatra's asp.



ISABELLE H. CONANT

EGYPTIAN COBRA (NAJA HAJE)

The Egyptian cobra differs from the common cobra of India in having a much narrower hood. It reaches a length of fully six feet. Egyptian snake charmers, who use the asp in their street performances, are said to be able to make it rigid like a stick by a pressure on the neck; some biblical scholars suggest that it was the asp that served as Aaron's staff in the famous countertransformation recorded in the Old Testament (Ex. vii, 8–12).

"Aspis" being a well-known classical name for a snake, it is not surprising that it should have been used as a technical name for various venomous snakes (the south European *Vipera aspis*, for example).

See also Cobra. (K. P. S.)

ASPAR (Flavius Ardaburius Aspar) (d. A.D. 471), Roman general of Alan descent, influential in the Eastern Roman empire under Marcian and Leo I. He led an East Roman fleet in 431 to expel the Vandals from Africa, but was defeated and withdrew in 434, in which year he was consul. He fought the Persians successfully in 441, but in 443 was defeated outside Constantinople by Attila. His influence increased when Marcian, who had formerly been in his service, became emperor in 450. He then became a patrician, and his son was appointed *magister militum* (master of the soldiers) in the east and soon afterward was also made a patrician. When Marcian died Aspar had his protégé raised to the throne as Leo I (Feb. 7, 457). Aspar was then at the height of

his power, with a Gothic army devoted to him. Leo, however, was not content to be a puppet and began more and more to rely on Isaurian supporters. For about four years there was a struggle for ascendancy in the East Roman empire between the two factions, Aspar's Germans and the Isaurians led by Zeno. Aspar managed to have the rank of Caesar conferred *c.* 470 on his son Patricius, although the latter was, like his father, an Arian, which caused much resentment in Constantinople; and Patricius was soon after betrothed to the emperor's daughter Leontia. But a conspiracy organized in 471 by the Isaurians and Leo led to the murder of Aspar and thus put an end to German domination over East Roman policy, which had lasted for several decades. (E. A. T.)

ASPARAGUS, a large genus of the lily family (Liliaceae) with about 150 species native from Siberia to southern Africa. Perhaps the best-known asparagus is the garden asparagus (*A. officinalis,* especially variety *atlilis*) cultivated as a green vegetable for its succulent spring stalks. Several African species, however, are grown as ornamentals (*see* below).

The plants are erect or climbing, sometimes more or less woody. The rhizomelike—or sometimes tuberous—roots give rise to conspicuous leaflike branchlets (cladodes); true leaves are reduced to small scales. Small greenish-yellow flowers in the spring are followed by red berries in the fall.

Garden Asparagus.—Economically this is the most important species of the genus. It is native from England to central Asia and is now cultivated and naturalized in most temperate and subtropical parts of the world. As a vegetable it has been prized by epicures since Roman times.

In the United States over 150,000 ac. are planted to asparagus annually for the commercial market. The production totals about 175,000 tons, of which almost 60,000 tons are sold for the fresh market and more than 115,000 tons are sold for processing. Increases in production for processing have resulted from advances in the methods of freezing and handling asparagus. Nearly half of the asparagus acreage in the United States is in California. The remainder is produced chiefly in New Jersey, Washington, Illinois and Michigan; several other states are lesser producers.

Commercial plantations are not undertaken in regions where the plant continues to grow throughout the year, for the shoots become more spindling and less vigorous each year; a rest period is required. In some warm, dry regions the rest period may be provided by withholding irrigation. Where the climate is favourable a plantation may be productive for 10 to 15 years. Asparagus can be grown in many kinds of soil with good drainage, but the best types for permanent plantations are deep, loose and light clays with much organic matter and light sandy loams. Asparagus will thrive in soils too salty for most other crops, but acid soils are to be avoided. In starting a crop, seeds are sown as early as possible, dropped 10 or 12 to a foot of row; the rows are usually 24–30 in. apart. The plants are grown for one year in nursery rows, then the year-old crowns (roots with stem attachment near the ground surface) are transplanted into the permanent fields as early in the year as the soil can be worked—in parts of the south and in California where climatic conditions are favourable even in fall or winter. Only the best and most vigorous crowns are used in transplanting; they are set 6 to 8 in. deep in loose soil and only 3 to 4 in. in heavier soil, placed 12 to 24 in. apart in rows 4 to 8 ft. apart, depending on soil and climate and on the end use of the asparagus.

Three classes of asparagus based on colour are marketed. Green spears and green with white butts are the kinds produced for the fresh market. Most canning asparagus is blanched white. The cutting season varies from 2 to 12 weeks, depending on age of plantation and on climate.

Ornamentals.—The several species prized for their delicate and graceful foliage are: *A. plumosus,* the asparagus fern or florist's fern (not a fern at all, however), which has feathery sprays of branchlets often used in corsages and in other plant arrangements; and *A. sprengeri* and *A. asparagoides* (the latter being the smilax of florists) likewise grown for their attractive lacy foliage, sometimes as house plants.

See Ross C. Thompson *et al.,* "Asparagus Culture," U.S. Department of Agriculture *Farmers' Bulletin No. 1646* (1958). (L. O. W.)

ASPARAGUS PEA (GOA BEAN), the name of a group of cultivated leguminous plants mostly derived from *Psophocarpus tetragonolobus,* native to India. All varieties are rapidly growing vines, 10 ft. to 50 ft. long, producing quadrangular, green-winged pods, 3 in. to 9 in. long. The tender young pods are eaten like string beans and have a distinct flavour resembling that of asparagus.

The seeds, which are about the size of peas, have a high protein content. Because of their extreme hardness when ripe, they are difficult to cook, hence usually only the immature seeds are eaten.

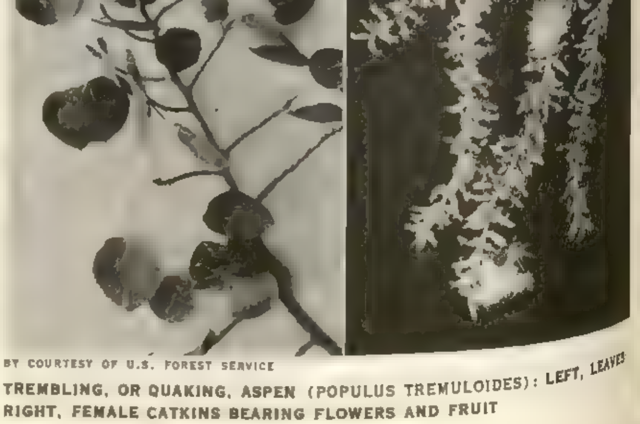
The plant is a quasi-perennial, bearing almost continuously for one or two years, and its cultivation is increasing in tropical countries; it is also grown as a cover crop.

ASPASIA (5th century B.C.), mistress of the Athenian statesman Pericles, was born in Miletus. Coming to Athens, she lived with Pericles from *c.* 450 B.C. to his death in 429. Pericles already had two young sons by an Athenian wife whom he had divorced and had himself carried a law in 451 requiring Athenian birth on both sides for citizenship. His son by Aspasia, who took his own name, was therefore illegitimate.

Aspasia was a vivid figure in Athenian society. She was continually attacked in comedy for her private life and public influence. She was irresponsibly accused of urging Pericles to crush Samos (Miletus' old rival) and to provoke the Peloponnesian War. But she was respected and remembered by philosophers. The associates of the young Socrates knew her well; she is a character in the *Menexenus* (falsely attributed to Plato); and she gave her name to a philosophic dialogue by the Socratic Aeschines. Shortly before the Peloponnesian War she was prosecuted for impiety but acquitted, and, when Pericles' two legitimate sons had died in the plague, his son by Aspasia was made an Athenian by special enactment and later became a general. After Pericles' death she is said to have lived with Lysicles (probably the man elected *strategos* for 428, regarded by Aristophanes unfairly as a vulgar demagogue). (R. ME.)

ASPECT RATIO. The aspect ratio of an airplane wing is the ratio of the span to the chord, the latter being the length of the straight line drawn from the leading to the trailing edge, at right angles to the length of the wing (*see* AIRPLANE). For a screen on which an image is projected, such as a motion-picture or television screen, the aspect ratio is the ratio of image width to image height (*see* MOTION PICTURES: *History: Wide Screens*).

ASPEN, a common name for several trees of the poplar genus (*Populus*), of which the common aspen of Europe, *P. tremula,* may be taken as the type. This is a tall, fast-growing tree with a



BY COURTESY OF U.S. FOREST SERVICE

TREMBLING, OR QUAKING, ASPEN (POPULUS TREMULOIDES): LEFT, LEAVES; RIGHT, FEMALE CATKINS BEARING FLOWERS AND FRUIT

slender trunk and gray bark that becomes rugged when old. The roundish leaves, toothed on the margin, are slightly downy when young but afterward smooth, dark green above and grayish green below; the long slender petioles, flattened toward the outer end, allow of free lateral motion by the slightest breeze, giving the foliage its well-known tremulous character. By their friction on each other the leaves give rise to a rustling sound. The flowers, which appear in March and April, are borne on pendulous hairy catkins, two or three inches long; male and female catkins are, as in the other species of the genus, borne on separate trees (dioecious).

The American aspen (*P. tremuloides*), called trembling aspen, closely allied to the European species, attains a maximum height of 100 ft. and a trunk diameter of 3 ft., but is usually much smaller. The bigtooth aspen (*P. grandidentata*) of North America has ovate or roundish leaves deeply and irregularly serrated on the margin.

P. tremuloides is the most widely distributed tree in North America, ranging from Labrador to the mouth of the Mackenzie river and the valley of the Yukon and southward to Pennsylvania, Missouri and Nebraska, and in the Rocky mountains and the Sierra Nevada to Chihuahua and Lower California, often ascending to an altitude of 10,000 ft. The aspen is an abundant tree in northern Great Britain, and is found occasionally in the coppices of the southern counties; it abounds in the forests of northern Europe, while in Siberia its range extends to the Arctic circle.

Aspen wood is light and soft, though tough; it is employed for various articles for which its lightness recommends it; in medieval days it was valued for arrows; the bark is used for tanning; cattle and deer browse on the young shoots and suckers. Charcoal prepared from it is light and friable, and has been employed in gunpowder manufacture. The powdered bark is given to horses as a worm medicine. The wood of both American species is manufactured into furniture, matches and wood pulp.

(E. S. Hr.; X.)

ASPENDUS (Gr. Aspendos; modern Bal-kiz kale in the Turkish *il* of Antalya), an ancient city of Pamphylia, strongly situated on an isolated hill on the right bank of the Eurymedon (Köprusu) river at the point where it issues from the Taurus mountains. The sea is about 7 mi. distant, and the river is navigable only for about 2 mi. from the mouth, but in the time of Thucydides ships could anchor off Aspendus. Really of pre-Hellenic date, the place claimed to be an Argive colony. It derived wealth from great salt pans by Lake Capria (possibly marked now by the winter marshes to the west of the site) and from a trade in oil and wool, to which the wide range of its admirable coinage bears witness from the 5th century B.C. onward. The city bought off Alexander the Great in 333 B.C., but, not keeping faith, was forcibly occupied by him. In due course it passed from Pergamene to Roman dominion and, according to Cicero, was plundered of many artistic treasures by Verres. It was ranked by Philostratus the third city of Pamphylia. In Byzantine times it seems to have been known as Primopolis, under which name its bishop signed at Ephesus in A.D. 431. In the middle ages it was evidently still a strong place but is now a small hamlet.

With the Roman theatre, the most perfect in Asia Minor and possibly the finest in the world, the ruins have earned for the place a mythical connection with Solomon's Sheban queen. On the flat summit of the hillock, divided in two by a small ravine and surrounded by a wall with three gates, lie the remains of the city. These include an agora, a basilica, a *nymphaeum*, a small theatre, an arcade and traces of rock-cut chambers of Phrygian style. In the plain below are large thermae and ruins of a splendid aqueduct. The huge theatre, half hollowed out of the northeast flank of the hill, had an auditorium of a circuit of 313 ft. with 40 tiers of seating and would accommodate 7,500 spectators. It was erected to the honour of the emperor Marcus Aurelius and his colleague Lucius Verus by the architect Zeno for the heirs of a local citizen. A relief of Bacchus over the centre of the theatre's colonnade is the "Bal-kiz" or "honey girl" from whom the present village takes its name.

(Wm. C. B.)

ASPERGES, the ceremony of sprinkling the altar and the people with holy water (*q.v.*) before High Mass in the Roman Catholic Church, so called from the opening words, *Asperges me, Domine, hyssopo* (Ps. li., 7), of the chant that accompanies the ceremony. The sprinkler is called aspergillum, and a vessel for holy water is called aspersorium.

See C. Goeb, "The Asperges," *Orate Fratres,* 2:338–342 (1927–28).

ASPERN-ESSLING, BATTLE OF, Napoleon's first serious reverse, was fought on May 21 and 22, 1809, between his French and allied forces and the Austrians commanded by the archduke Charles (*see* Napoleonic Wars). After the repulse of his initial invasion of Bavaria in April, Charles's army had retired eastward in two groups. The French entered Vienna on May 12 to find the bridges across the Danube cut and the enemy reassembled on the north bank. Napoleon accordingly determined to force a crossing six miles below Vienna via Lobau, the largest of the islands which split the swollen river into smaller channels about that point. On May 21, by midday, 25,000 French troops had reached the farther bank, where the villages of Aspern and Essling secured their left and right flanks. Although the state of the bridges delayed the arrival of reinforcements, they maintained their bridgehead until nightfall against the heavy but badly coordinated attacks of Charles's 95,000 men. Reinforced substantially during the night, the French resumed battle at first light on May 22. Masséna cleared Aspern of the enemy who had penetrated it, and Lannes retook Essling, which had fallen early in the day. A general French offensive in the centre was halted, however, and Aspern was again lost. Furthermore, the bridges to the right bank were severed, and at 11 A.M. Napoleon called off his attack. Furious fighting accompanied the costly French retreat to the Danube during the afternoon. Determined French resistance, their own exhaustion and Charles's indecision prevented the Austrians from routing the French before they could withdraw to Lobau under darkness. The French suffered 20,000 casualties (Lannes being killed), and the Austrians 23,000. Early in July the French were able to cross the Danube again to defeat Charles at the battle of Wagram.

(J. H. N.)

ASPHALT, an organic material that is sticky, black or brown in colour and of a consistency varying from heavy liquid to solid. Asphalt, whose chemical composition is too complex and variable to be determined precisely, is obtained either from the distillation of petroleum or from natural deposits. Asphalts from the two sources resemble each other in all respects except that natural asphalt, believed to be an early stage in the breakdown of organic marine deposits into petroleum, often contains minerals while petroleum asphalt does not. Asphalt is of great commercial value, with its most important uses in road building, waterproofing, roofing, floor tiling and automobile manufacturing.

Sources.—The earliest known asphalts occurred in springs in the east and to some extent in Europe. Later, deposits of solid, semisolid and liquid asphalts, usually mixed with minerals ranging from dust to sand, were found and mined. Lake asphalt from Trinidad was the first large commercial source but natural asphalt has declined in relative importance as petroleum became the major source. Gilsonite, wurzilite and similar vein asphalts that are very hard and are mined like coal have special uses in heat-resistant enamels. Petroleum asphalt is produced in all consistencies from light road oils to heavy (high viscosity) industrial types.

History.—The use of asphalt is very old. Probably its earliest use was as a water stop between brick walls of a reservoir at Mohenjo-Daro (beginning in the 3rd millennium B.C.) in India. Early Buddhist traditions mention "earth-butter." In the middle east it was extensively used for roads and water works, such as flood control; a king left an inscription to the effect that he had found his realm in mud and had left it "laced with roads glistening with asphalt."

Composition.—Asphalts are often referred to as hydrocarbons (hydrogen and carbon compounds) but this is seldom technically correct. For the most part they consist of hydrocarbons that have combined with nitrogen, sulfur and oxygen. No method for accurately analyzing asphalt has yet been discovered. Its constituents appear to be enormously variable, complex and subject to rapid change under different methods of treatment, although

possessing rather stable physical properties except when heated. Methods of analysis have usually consisted of determining relative molecular weights, general nature of compounds and elemental composition rather than specific chemical structure.

Uses.—*Asphalts for Roads.*—A great variety of road uses exists, from light oil dust layer treatments, which by repetition may gradually build up a permanent surface, to precisely designed road surfaces of graded mineral-asphalt composition up to eight inches thick. The lowest-cost method, aside from the dust layer method, is the spraying of road oil on the prepared surface, followed by the application of granular aggregate, forming what is termed a "seal coat." The seal may consist of single, double or multiple coats. The next method in increasing order of cost is the mixing of local materials in place with road oils, by traveling machinery, to form a low-cost but also usually a low-quality pavement. A considerable use of asphaltic oils has been made for mixing directly with soils to form waterproof bases or subbases for pavements. This is termed "soil stabilization" and for success requires special oils.

Asphalts for Hydraulic Uses.—These uses include applications to canal linings, dam facings, river and sea revetments, beach erosion barriers and reservoir linings, and injection into sands and fissured rock formations to stop the flow of underground water. Linings vary from thin, sprayed membranes covered with earth for protection against weathering and mechanical damage to thick surfacings similar to road pavings, and to stone riprap bound with asphalt. In general, mixtures used for hydraulic purposes employ more asphalt by percentage than do road work mixtures and are less mechanically resistant.

Asphalts for Industrial Use.—These normally consist of road type or steam-refined asphalts that have been intensively oxidized. The principal industrial uses are for roofs, coatings, floor tiling, automobile manufacture, battery manufacture, soundproofing, waterproofing and other specialities in great number. A considerable amount of industrial-type asphalt also is used in hydraulic works.

Asphaltic Emulsions.—Asphaltic emulsions consist of fine globules of asphalt suspended in water and prevented from coagulating by protective surfaces furnished by chemicals mixed into the asphalt prior to emulsifying. The emulsification is carried out with a colloid mill. The uses in general parallel those of regular asphalts except that emulsions are not used in heavy paving mixtures. An advantage of emulsified asphalt is that it does not have to be heated before being applied.

Mechanical Properties.—Asphalt is thermoplastic and subject to variable mechanical reactions; these properties are affected by the conditions of loading and by the presence of solvents remaining from distillation or added. Mechanical resistance to deformation can be measured in terms of poise, which is an absolute unit of viscosity; resistance can be measured in all ranges of consistency and at all ordinary temperatures. Formulas also exist for transforming some older units of resistance to absolute units.

In asphalts deviation from pure liquid, or Newtonian, flow is common, with various forms of plastic behaviour being found. The deviation also can be measured and expressed in terms of poises. The sliding plate viscometer was the most suitable instrument for measuring viscosity early in the sixth decade of the 20th century.

Elasticity appears in asphalts under certain conditions. In the Newtonian or pseudo-Newtonian types it appears as a roentgen effect, or reaction to impact; in oxidized industrial asphalts it is a weak solid-type, partly static reaction. These effects have various applications in practical use. The roentgen effect is of special importance in road use, where dynamic impact is high.

Mechanics of Asphalt-Mineral Mixtures.—The mechanical properties of asphalt are of little significance except when it is used as a binder or adhesive. The reactions that occur in binding and adhesion are exceedingly complex, involving viscosity, plasticity and granular solid structure. For static loadings or loadings at low velocities, the triaxial form of test, which applies loads to a completely confined test specimen, is the most scientific and informative. For impacts, there are various vibratory methods, some for field and some for laboratory use.

The history of asphalt-testing methods has been influenced by the somewhat paradoxical fact that although the subject is very complex scientifically, good results in road work can be obtained by trial and error, and this is the manner in which such work proceeded in former times. Research on testing has actually largely taken the form of rationalizing and improving work done originally by trial and error at great public cost. *See* GEOCHEMISTRY: *Bioliths;* TRINIDAD AND TOBAGO; GILSONITE; OZOCERITE; ROADS AND HIGHWAYS: *Construction;* HOUSE DESIGN: *Materials;* BLACK VARNISH.

ASPHALT TILE: *see* FLOOR COVERINGS.

ASPHODEL, a much misunderstood common name for several flowering plants belonging to the lily family (Liliaceae). The asphodel of the poets is often a narcissus; of the ancients it is either of two genera, *Asphodeline* or *Asphodelus*, containing numerous species in the Mediterranean region.

They are hardy herbaceous perennials with narrow tufted radical leaves and an elongated stem bearing a handsome spike of white or yellow flowers.

Asphodelus albus and *A. fistulosus* have white flowers and grow from 1½ to 2 ft. high; *A. ramosus* is a larger plant, the large white flowers of which have a reddish-brown line in the middle of each segment.

Bog asphodel (*Narthecium ossifragum*), of the same family, is a small herb growing in boggy places in Great Britain, with rigid, narrow, radical leaves and a stem bearing a raceme of small golden-yellow flowers. In the United States the American bog asphodel (*N. americanum*), of the pine barrens of New Jersey and Delaware, and the western bog asphodel (*N. californicum*), of the coast ranges of California and Oregon, are both rare plants.

In Greek legend the asphodel is the most famous of the plants connected with the dead and the underworld. Homer describes it as covering the great meadow, the haunt of the dead. It was planted on graves and is often connected with Persephone. Its general connection with death is due no doubt to the grayish colour of its leaves and its yellowish flowers, which suggest the gloom of the underworld and the pallor of death. The roots were eaten by the poorer Greeks; hence such food was thought good enough for the shades.

The asphodel was also supposed to be a remedy for poisonous snake bites and a specific against sorcery; it was fatal to mice, but preserved pigs from disease. According to Herodotus, the Libyan nomads made their huts of asphodel stalks.

ASPHYXIA, a term in medicine signifying suffocation or any interference with oxygenation of the blood. It is the result of many causes and may be seen at any stage of life. *See* RESPIRATORY SYSTEM, DISEASES OF. (F. L. A.)

ASPIDISTRA (CAST-IRON PLANT), a small genus of the lily family (Liliaceae) native to China and Japan. The plant will withstand adverse conditions and thus is considered among the most useful foliage plants for growing indoors. *Aspidistra elatior* bears green or white striped leaves, about 18 to 20 in. long, and when pot-bound produces small, purple, cup-shaped flowers close to the soil. (R. T. V. T.)

ASPIRIN is a trade name for acetylsalicylic acid, introduced into medicine by Hermann Dreser in 1893. It is widely used as an antipyretic and analgesic.

Like other salicylates, aspirin will relieve the joint pains in acute rheumatic fever without, however, influencing the course and complications of the disease. The symptoms of overdosage ("salicylism") include ringing of the ears, headache, dizziness, dimness of vision, mental confusion, nausea, vomiting and diar-

rhea.

Some individuals are hypersensitive to aspirin as manifested by skin rashes and anaphylactic phenomena. Aspirin may also cause gastric irritation.

See also SALICYLIC ACID.

ASQUITH, HERBERT HENRY: *see* OXFORD AND ASQUITH, HERBERT HENRY ASQUITH, 1ST EARL OF.

ASS, a member of the horse family, typified by the domestic donkey. The ears are long, the long hairs on the sides and end of the tail form a tuft, the mane is hogged or erect and there are no horny bare patches on the hind leg just below the hock or heel joint. A dark stripe runs along the back and another crosses it over the shoulder; the legs are often banded with dark stripes. The voice is a roaring "hee-haw" bray. Gestation lasts 12 months, a month longer than in the horse.

When an ass or donkey is mated with a horse, the offspring is a mule (*q.v.*).

The common donkey is a domesticated race of the African wild ass, *Equus asinus*, of Ethiopia and other parts of northeast Africa, which with some exceptions is larger than most domestic varieties. In Somaliland the wild asses lack the shoulder stripe and have conspicuous bands on the legs so that they are regarded as a distinct subspecies.

The wild ass of Asia, *E. hemionus*, is generally similar but with less gray and more rufous or fawn in the coat colour; the stripes along the back and across the shoulder and the bands on the legs are also generally present. Five subspecies are recognized: the Syrian wild ass, *E.h. hemippus*, from the Syrian desert but now nearly extinct; the onager, *E.h. onager*, of northwest Iran to Soviet Turkestan; the Indian wild ass, *E.h. khur*, from western India and Baluchistan, in which the shoulder stripe and leg bands are often pale or wanting; the kiang, *E.h. kiang*, of the high plains of Tibet at a height of 15,000 ft. and more, a large ass with pale back stripe, no band on the legs and little indication of the shoulder stripe; and the kulan, *E.h. hemionus*, from central Mongolia.

Wild asses inhabit arid, semidesert plains where the vegetation is sparse and coarse; the domestic donkey does well on very coarse food and is extremely hardy under rough conditions, hence its great usefulness to man as a beast of burden in places where horses cannot flourish.

The donkey's occasional obstinacy in refusing work too heavy for it has become proverbial, but its equally proverbial stupidity has probably become legendary through its reaction to brutal treatment and neglect. It is naturally patient and persevering, responding to gentle treatment with affection and attachment to its master. (L. H. M.)

ASSAB, a port of Eritrea, Ethiopia, on the Eritrean coast, 60 mi. N. of the strait of Bab el Mandeb, lies at the entrance to Assab bay in a rainless region of very high temperatures. Pop. (1956 est.) 4,248. The federation between Ethiopia and Eritrea in 1952 made possible the development of the port as a natural outlet for the southern half of the country.

The port, which is connected by a good truck road with the main Addis Ababa-Asmara highway, was being enlarged and modernized in the early 1960s. About one-third of Ethiopia's external trade passes through Assab. The salt-evaporation pans produce about 125,000 tons annually.

Assab was for many centuries a terminus of caravan routes across the Danakil desert from the highlands, and there are Sabaean ruins 10 mi. S. of the town. It acquired a greater significance after the opening of the Suez canal, and the area was purchased in 1869 by Giuseppe Sapeto from the sultan of Raheita (30 mi. S.). It was later taken over by the Società di Navigazione Rubattino which was acquired by the Italian government in 1882, Assab thus becoming the first Italian colonial possession in Africa. (G. C. L.)

ASSAM, the northeastern state of the Republic of India, is almost cut off from the rest of the country on the west by East Pakistan, and borders Bhutan (N.W.), Tibet (N.) and Burma (E.) Area 47,098 sq.mi. excluding the North East Frontier Agency (*q.v.*; area 31,438 sq.mi.). In British times the province of Assam included also the district of Sylhet (*q.v.*) in the south,

PAUL POPPER LTD.

SAMPAN SKIFFS ON THE BRAHMAPUTRA RIVER, ASSAM, INDIA

most of which is now part of East Pakistan, and the governor of Assam had supervision over Manipur which, on partition in 1947, became a union territory. Pop. (1951) 9,043,707; (1961) 11,872,772.

Physical Geography.—Assam proper comprises the valley of the Brahmaputra as far as the foothills of the Himalayas on the north where lies the frontier with Bhutan occupying the Himalayas to the west. The North East Frontier Agency covers the Himalayas in the northern and northwestern part of the state. The valley is roughly 500 mi. from east to west and 50 to 100 mi. wide and is bounded on the south by a succession of hill masses—the Garo, Khasi and Jaintia hills beyond which lies Pakistan, the Barail range on the Manipur border and the Patkai hills on the Burmese border. The agency has a long frontier with Tibet and China. Near the head of the valley a number of rivers unite to form the Brahmaputra (*q.v.*) proper; by far the most important is the Tsangpo (often called Brahmaputra on western maps), which after flowing eastward through Tibet for hundreds of miles turns south through the main Himalayan ranges in great gorges to fall in a series of rapids to the Assam valley where, 1,000 mi. from the sea, it is only 400 ft. above sea level. From there it follows a sluggish course meandering, dividing and reuniting, frequently many miles wide so that periodic flooding renders much of the Assam valley of little use. The various hill areas round the valley are named after the hill tribes inhabiting them; at the far eastern end the great mountain barrier became known during the early part of World War II as "The Hump" over which supplies were flown to western China then resisting the Japanese invasion.

Geologically the hill mass of southern Assam is a detached portion of the Indian plateau consisting of Pre-Cambrian schists and gneisses overlain in places by little folded Cretaceous and Tertiary rocks, sometimes with seams of coal and also with nummulitic limestone beds. The Himalayan and Burmese ranges are intensively folded, apparently against and around the stable block of the Assam hills, and include rocks up to Late Tertiary. Oil occurs associated with Mid-Tertiary rocks in tight anticlinal folds, notably at Digboi. Folding has not ceased; earthquakes are frequent in the mountains of the northeast and especially severe were those of 1897, affecting the Garo-Khasi hills, destroying Shillong and killing 1,542 people, and of 1950.

Climatically the cool season (Jan. average 61° F. in the valley) is marked by the northeast monsoon blowing down the valley and fogs are common and a little rain. Assam escapes the normal Indian hot dry season; some rain occurs from March onward but the real force of the monsoon winds is felt from June onward. They blow at right angles to the Assam hills, and Cherrapunji (*q.v.*) overlooking the valley of the Surma (in Pakistan) is reputed to be the wettest place in the world, with an annual average of more than 400 in. By the time the winds have crossed the hills they bring little rain to the valley where Gauhati averages only 67 in. Average temperature is kept moderate (84° F. in the hottest month). At high levels snow falls.

The range in climate is reflected in natural vegetation—from evergreen rain forests resembling but floristically different from equatorial forests, through evergreen oak and pine, to rhododendron thickets and the snow line. Timber is valuable. Elephants are numerous in the foothills; the Kaziranga game reserve is the last great Indian stronghold of the one-horned rhinoceros and has herds of buffalo and swamp deer. Other animals besides the ordinary Indian fauna include the clouded leopard, Temminck's cat, Malayan bear, Malayan sambar, musk and mouse deer, red serow, pigmy hog and white-browed gibbon. (L. D. S.)

History.—Sources for the history of Assam are limited to Ahom (*see* below) chronicles of doubtful accuracy, references in Burmese chronicles, a few inscriptions and copper plates, coins for the later periods and Muslim accounts of the wars of the 16th and 17th centuries. From remote antiquity the valley was occupied by a Tibeto-Burman-speaking people. This stock still forms the bulk of the indigenous population.

Indo-Aryan settlement in the valley must have begun before the opening of the Christian era. Three lines of kings are known to have ruled from the 6th to the 12th century. In the 13th century the first Muslim invasions broke up the old kingdom; about 1515 a Koch dynasty carved out lands that now comprise the district of Cooch-Behar (*q.v.*) and lower Assam, and which soon split into an eastern and a western kingdom.

Meanwhile the Burmese Shans, known as Ahoms, who were to give their name to the country and rule it for centuries, had crossed the low ranges at the head of the valley and were consolidating their power in upper Assam. The traditional date of the Ahom invasion according to their chronicles is A.D. 1228, but students of Burmese history consider a date in the late 15th or early 16th century more probable (*see* AHOM). They at once came into conflict with the Kacharis, whose leaders retreated down the south bank of the Brahmaputra.

In 1527 Muslim marauders from Gaur (*q.v.*) invaded the Ahom kingdom for the first time and were defeated. The Ahoms, pressing west against the Kacharis, sacked Dimapur, their capital, and forced them into the north Cachar Hills, where they built a new capital at Maibang. Surviving ruins show that the Kacharis at this period had attained a considerably higher state of civilization than their conquerors. Wars with the Muslims occupied much of the 17th century, and in 1662 lower Assam was ceded to the Mughal emperor Aurangzeb. In 1706 the Kacharis were driven out of Maibang and established their last capital at Khaspur in the plains of Cachar. About this time the Ahom king Rudra Singh became an orthodox Hindu, and in the reign of his successor Sib Singh (1714–44) Hinduism became the predominant religion.

The country had frequently been distracted by rebellions in which both sides showed appalling brutality, and by 1792 such was the state of affairs that the king, Gaurinath, sought and received aid from the British in Bengal. This aid was soon withdrawn, however, and in 1816 a claimant to the throne called in the Burmese, who plundered the country and returned the following year. After further disorder and a period of direct British rule (1826–32), Assam was in 1838 incorporated in Bengal (*q.v.*) and remained a part of that province until a separate chief commissionership was set up in 1874. This arrangement continued, with one interval, until 1919, when Assam became a governor's province.

During World War II the Naga Hills, especially the area around Kohima, were the scene of bitter fighting between the British 14th army and the Japanese forces which had occupied Burma in 1942. Assam became one of the main supply routes for all the Allied forces operating in this area.

On Jan. 26, 1950, when the constitution of India came into force, Assam became a state of the republic.

A movement for independence, which started in 1955 among the Naga tribes in the Tuensang frontier division of the North East Frontier Agency and in the Naga Hills district of Assam, developed into a rebellion in 1956–57, necessitating operations by the Indian army. As of Dec. 1, 1957, the whole area affected was placed under the direct administration of the central government of India.

The rebellion continued, however, and although Nagaland became a separate (the 16th) state within the Indian Union in 1962 (inaugurated Dec. 1, 1963) a cease-fire was not agreed upon until 1964. Despite breaches the cease-fire continued in force during talks (1964–66) between the Indian government and the Naga rebels who demanded independence.

During the same period the Chinese, disputing the McMahon Line as boundary between India and Tibet, crossed it into the North East Frontier Agency area of Assam to occupy an Indian outpost at Longju. In much greater strength (September 1962 they deeply penetrated Agency territory. In December, however they voluntarily withdrew behind the McMahon Line.

On Feb. 28, 1966, Mongoloid rebel groups, who demanded a separate Mizo (*q.v.*) state, began to fight as guerrillas against the Indian Army. (*See* also INDIA: *History;* NAGALAND.)

(J. P. M.; F. R. A.; X.)

Population and Administration.—According to the 1961 census the population of Assam was 11,872,772. The population is heterogeneous and includes many people of distinctly Mongoloid physical type, among them such tribal groups as the Khasis and the Nagas. About 40% are recorded as speaking Assamese and about 24% Bengali. About 65% are Hindus, 22% Muslims, and most of the remainder professing Christianity or tribal beliefs. Labour for the tea gardens has brought in many workers from Bihar, while after 1911 many land-starved peasants from Mymensingh in Bengal settled in the valley. Hindi, Oriya, Mundari, Nepali and a variety of languages and dialects classified under the general category of Tibeto-Burman languages (*q.v.*) are also spoken. There has never been a regular or adequate census of the tribal population in the state for the administration in the North East Frontier Agency and other tribal areas rests lightly.

The state government has a unicameral legislature under a governor and cabinet. The N.E.F.A. is completely separate from Assam administratively. The governor rules the agency with the help of an adviser in Shillong and the ultimate responsibility for the area rests with the external affairs ministry of the government of India. Assam comprises the 11 administrative districts of Goalpara, Kamrup, Darrang, Nowgong, Sibsagar, Lakhimpur, Cachar, Garo Hills, Khasi-Jaintia Hills, Mizo Hills and Mikar and North Kachar Hills. (S. CH.)

Social Conditions.—In 1956–57 an estimated 1,155,000 children were receiving education, of whom more than two-thirds were boys, and 90% came from rural areas. Primary education was being given to 61.7% and secondary education to 16.3% of the children in the respective age groups. Compulsory primary education was in force for children of 6–12 in 13 towns and 4,405 villages. The 1961 census recorded that literacy among males was 35.5% and among females only 14.6%. Gauhati (*q.v.*) is the seat of Assam's only university. In 1955 birth and death rates were respectively 33.9 and 15.6 per 1,000 persons. Seventeen welfare extension projects, operating through 83 centres and covering 300,000 people, were providing recreational and cultural facilities for women and children. (S. B. L. N.)

The Economy.—In comparison with most of the states of India Assam is still relatively underpopulated and has land awaiting settlement and development. Government reserve forests cover 6,350 sq.mi. (1951–52). Among the many valuable hardwoods are sal (*Shorea robusta*), bonsum (*Phoebe hainesiana*) and hollock (*Terminalia myriocarpa*) but much forest land is too inaccessible to be of economic importance. Bamboo cane is also exported. In the Assam valley rice is the principal crop, averaging in the state more than 4,000,000 ac. and a production of nearly 2,000,000 tons. Large areas of land liable to flooding and changes of river course are at present classed as "cultivable waste." The western end of the valley comes within the jute-growing belt of India. Tea is the most important article of commerce and its cultivation is a basic factor in the development and economy of Assam. More than 1,000 tea gardens covering nearly 400,000 ac. and employing over 500,000 people are found especially on the sloping land of the valley sides but also, provided soil drainage is good, on the plains. The Assamese are too concerned with their own holdings and

too prosperous to seek work on tea plantations; the necessary labour is brought in from Bihar and central parts of India. Legislation ensures the labourers' protection and repatriation but many settle permanently at the end of their engagement, indeed less than a quarter of the state's population are native-born Assamese. Other crops include sugar cane, oilseeds and mustard, with short-stapled cotton, millet and maize in the hills. Potatoes and oranges are exported in large quantities from the Khasi hills. The hill tribes practise shifting cultivation, which creates an erosion problem, but permanent irrigated terraces are found in some areas.

Cottage industries, mainly sericulture and hand weaving, employed about 2,000,000 persons in the early 1960s. Modern industry has scarcely reached Assam but the refinery at Digboi processes about 250,000 cans of petroleum annually from the nearby oil fields. A little coal is quarried, and many deposits are not yet touched. Limestone is quarried on the southern fringe of the Khasi hills, and sillimanite from the plateau above is used in glass furnaces in India and Europe.

Shillong (*q.v.*), the state capital pleasantly situated on the cool height of the plateau, has no railway but is reached by motor road from Gauhati where the two main sections of the Assam railway are separated by the Brahmaputra. The direct line from there to Calcutta lies through East Pakistan and there has been no through running since partition in 1947. By the construction of a short link line, Calcutta can now be reached by a tortuous route round the north of East Pakistan but one lying entirely in Indian territory. The only direct access to Assam from the main part of India is by air.

ASSAMESE LANGUAGE, the Indo-Aryan tongue spoken in the Assam valley. In its grammar it closely resembles Bengali (*q.v.*), since both are derived from a common source. Its vocabulary is mainly tadbhava. Tadbhava means "of the same character as" Sanskrit, contrasted with tatsama, "identical with" the Sanskrit word. The French word ange is tadbhava, while angelus is tatsama, identical with the Latin.

The Assamese language has been affected by its proximity to Tibeto-Burman dialects both in vocabulary and in structure, as in the use of pronominal suffixes, and in phonetics, though following Bengali generally in its accentuation.

The chief glory of Assamese literature is in history. The *buranjis* or historical works are voluminous and have been carefully preserved.

ASSASSIN, a general term for one who murders by treacherous violence (properly *hashishin*, a taker of hashish), originally a name applied to the branch of the Isma'ili sect of Shi'ite Muslims founded by Hasan ibn al-Sabbah at the end of the 11th century.

Hasan, a native of Khurasan and a supporter of the official Isma'ili doctrine of the Fatimid caliphate in Cairo, became the leader of the great Isma'ili revival in Persia directed chiefly against the new Seljuk regime (*see* SELJUKS). After the death of the Fatimid caliph Mustansir in 1094, Hasan and the Persian Isma'ilis refused to recognize the new caliph in Cairo and transferred their allegiance to his deposed elder brother Nizar. Nizar and his son were murdered in prison in Egypt, but, according to Assassin tradition, an infant grandson was smuggled out to Persia and there brought up by Hasan ibn al-Sabbah to found a new line of Nizari imams. Hasan and his two successors in the grand mastership of the Persian Isma'ilis, Kiya Buzurgumid (1124–38) and Mohammed (1138–62), claimed only to be representatives of the imams; but the fourth grand master, Hasan ibn Mohammed (1162–66), proclaimed himself the son of the infant brought from Egypt and the first of a new line of open imams (now represented by the Aga Khan; *q.v.*). The Assassins made a number of changes in Isma'ili doctrine and practice, the most significant, from the point of view of the outside world, being the adoption of "assassination" (*i.e.*, the murder of the sect's enemies) as a sacred religious duty.

The open history of the sect begins in 1090, when Hasan ibn al-Sabbah, the first "Old Man of the Mountain," seized the castle of Alamut in an impregnable valley near Kazvin. By the end of the 11th century he commanded a network of strongholds all over Persia and Iraq, a corps of devoted terrorists and an unknown number of agents in the camps and cities of the enemy. In Alamut, which remained the headquarters until its destruction by the Mongols, the grand master presided over a hierarchy of propagandists (*da'i*), terrorists and lay brothers and directed the policies and activities of the sect. Seljuk attempts to capture it were unavailing, and soon the Assassins were claiming many victims among the generals and statesmen of the caliphate, including even some of the caliphs themselves. The Fatimid government in Cairo, with which the Assassins were now on terms of open hostility, also suffered from their attentions, though to a lesser extent.

At the beginning of the 12th century the Persian Assassins extended their activities to Syria, where the expansion of Seljuk rule, followed by the arrival of the crusaders, had created a favourable terrain. The Syrian population had long included important extremist Shi'ite minorities who might be expected to welcome the Assassin emissaries. After a period of preparation the Assassins seized a group of castles in the Jebel Ansariya, the chief of which was Masyaf, and from there waged a war of terror against Turks and crusaders alike. They seem to have remained under the orders of Alamut, though there is evidence that Rashid al-Din Sinan (d. 1192), the greatest of the Syrian grand masters, acted independently. After two attempts on the life of Saladin, he appears to have reached some understanding with him against the common enemy. After the death of Sinan the authority of Alamut was restored over the Syrian castles.

The end of the power of the Assassins came under the double assault of the Mongols and of their deadliest enemy, the Mameluke sultan Baybars. In Persia the Mongol general Hulagu captured the Assassin castles one by one with surprising ease; in 1256 Alamut itself fell, and the last grand master, Rukn al-Din Khurshah, was compelled to surrender. He was hanged shortly after. In Syria the Assassins tried to ingratiate themselves with Baybars, but without success. One by one the Syrian castles were subjugated and placed under Mameluke governors, the last, Kahf, falling in 1273. Henceforth the sect stagnated as a minor heresy, with little or no political importance. Its followers are still to be found in Syria, Persia and central Asia, with the largest group in India and Pakistan, where they are known as Khojas and owe allegiance to the Aga Khan.

The term assassin was brought to Europe by the crusaders from Syria and derives from the terrorists' alleged practice of taking hashish to induce ecstatic visions of paradise before setting out to face martyrdom. The stories told by Marco Polo and others of the gardens of paradise into which the drugged devotees were introduced to receive a foretaste of eternal bliss are not confirmed by any known Isma'ili source. The fame of the sectaries soon spread in the west, and before long perfervid imaginations detected the hand of the "Old Man of the Mountain" in political murders and attempts even in Europe.

ASSAULT AND BATTERY. Under common law in the United States and England, and by statute in many states of the United States, an assault is generally defined as an attempt to commit a battery, or the commission of an unlawful act which causes another reasonably to fear an imminent battery. A battery is an unlawful application of physical force to another. The legal concepts of assault and battery are designed to protect the individual from rude and undesired physical contact or force and from the fear or threat thereof.

The protection afforded by the law against assault does not

extend to the mere possibility of harm or to the threat of a battery in the distant future. Rather, an apparent, imminent danger is required, and some overt act which appears to threaten a battery is prerequisite to an assault. Thus, words alone do not constitute an assault.

With respect to the actual commission of a battery, the degree of force is unimportant; a battery may be accomplished by a mere touching. Moreover, the force used need not be direct. For example, one may commit a battery not only by coming into physical contact with another but also by striking his cane or horse, administering poison or drugs, or even communicating a disease.

There are some instances in which force may be lawfully employed without the consent of the victim. For example, due execution of the law, defense of one's person or property, or reasonable correction of a child may warrant the use of force. Generally speaking, however, lack of consent by the person to whom force is applied results in a battery. Nonetheless, even where consent has been given, the law will not recognize it when obtained by fraud or duress, when given by one too young or too feeble-minded to be capable of consent, or when given in connection with a battery so serious that the law could not permit consent, as in the case of a serious beating or a breach of the peace. One is presumed, however, to consent to certain physical contacts normal to everyday life, such as a tap on the shoulder or jostling on a crowded bus.

There are two forms of legal redress for assault and battery: a civil or private action by the victim for damages, and a criminal prosecution in the name of the state. Certain differences exist between the civil and criminal law with respect to assault and battery.

In a civil case, the victim of an assault must show that he has been harmed in some manner. Consequently, if he was unaware of any danger at the time of the assault, he cannot recover in a civil suit. The purpose of a criminal prosecution, however, is the punishment of conduct prohibited by society through its laws. Therefore, in the United States, one who has committed an assault is criminally responsible for his conduct irrespective of whether his intended victim knew of the attempt. In England, however, the rule is different. There, neither a criminal nor a civil assault has occurred unless the victim knew of the threat.

In both civil and criminal law, a battery may take place even though the victim is unaware of the use of force against him at the time of its application.

Assault and battery generally require an intent to harm. However, where one has intentionally placed another in fear of a battery, although without any intention of actually committing one, English courts and most courts in the United States hold that the party is guilty of a criminal as well as a civil assault. A few courts in the United States, however, refuse to hold such a party guilty of criminal assault, reasoning that neither criminal intent nor ability to harm exists in such a case. A typical situation is that in which one points an unloaded revolver at another, threatening to shoot.

A purely accidental injury is not punishable as a battery. However, where one accidentally causes injury to another during the commission of an unlawful act, he is guilty of a battery. Moreover, careless conduct may result in an action for damages or a criminal prosecution. Thus, a civil action may be brought for an injury caused by the ordinary negligence of another. A criminal prosecution, however, cannot be maintained for an injury caused by ordinary negligence; gross, or criminal, negligence, involving a high degree of carelessness, is required in such an action.

England and some jurisdictions in the United States define certain types of assault (such as assault with a deadly weapon, with intent to kill, etc.) as "aggravated" assault, with convictions carrying higher penalties than ordinary assault.

Under military law, assault is defined as an attempt or offer with unlawful force or violence to do bodily harm to another. An assault against a superior officer is generally punishable by death in time of war. (C. R. Se.)

ASSAYING, the process of determining the proportion of metals in ores and metallurgical products. There has been a tendency to restrict the term to methods for the determination of the precious metals and to fire methods (reducing the metallic content of an ore sample to metal in a small analytical crucible for the determination of base metals such as lead and tin. Wet chemical analytical procedures and spectrographic methods of analysis are usually termed analyses instead of assaying.

The methods of assaying had their beginnings in antiquity, before the dawn of chemical knowledge. They evolved from the fumbling experiments of ancient alchemists and goldsmiths who were striving to find and produce the precious metals. Successful recovery processes were devised and quantitative procedures developed at an early date. Trial by touchstone and by fire is mentioned by Theophrastus (*c.* 371–*c.* 288 B.C.). Germination of the seeds of modern chemistry and metallurgy can be seen in the *Probierbüchlein*, "The Little Book on Assaying," and in Lazarus Ercker's *Treatise on Ores and Assaying*, both published in the 16th century.

Many of the operations of fire assaying are carried out today much as they were then. These ancient methods are still taught in university courses for metallurgists because they offer a convenient way of studying the reactions of igneous chemistry. They are still used in industry because modern science has been unable to develop better methods of determining the precious-metal content of ores. This is largely due to the sampling problem. The precious metals tend to occur in ores as ductile particles and each particle has a high value. Hence the sample of ore must be relatively large so that the chance variation in the number of precious-metal particles will not change the value of the sample beyond the allowable error. Large samples can be economically and accurately assayed by the fire methods but spectrographic methods of analysis are not adapted to operating on large sample portions and wet chemical methods, involving the complete decomposition of large samples, would be very expensive. Leaching with cyanide solution has been used as an analytical process but usually an important part of the values remains in the undecomposed ore particles and is not recovered.

UNITS USED IN ASSAYING

In the United States, Canada and South Africa the proportion of precious metals is expressed as troy ounces per short ton (2,000 avoirdupois pounds) of ore. A system of assay-ton weights is used in weighing the assay portion of ore which is taken for the assay process. The assay ton contains the same number of milligrams (29,166⅔) as there are troy ounces in a short ton. Hence the number of milligrams of precious metals found in an assay ton of ore indicates the assay in troy ounces per short ton.

In England and Australia the long or gross ton of 2,240 lb is used. It has an equivalent assay long ton of 32.667 g. The gold assay in British countries is commonly reported in pennyweight (dwt.), a troy weight containing $\frac{1}{20}$ troy ounce.

In Mexico, South America and other countries using the metric system the proportion of the precious metals is reported in kilograms and grams per metric ton of ore. The metric ton contains 1,000.000 g.; consequently, 1 mg. of gold from a 10-g. assay portion of ore indicates 100 g. of gold per metric ton of ore.

Assays of lead and copper bullion are reported in the same units as those used for ores. Gold and silver bullion assays are universally reported in fineness, or parts per 1,000. The gold content of jewelry is reported in carats, or $\frac{1}{24}$ parts. Twenty-four-carat gold is pure gold and 18-carat gold is $\frac{18}{24}$ or 75% gold. Eighteen-carat gold is 750 fine.

ASSAYING FOR GOLD AND SILVER

Ores are assayed for gold and silver by the following steps:

1. Sampling: taking a representative portion of ore for assay.
2. Fusion: decomposing the assay portion by melting with fluxes and reagents to produce a lead button containing the precious metals and a slag which is discarded.
3. Cupellation: melting the lead button in an oxidizing atmosphere to oxidize the lead and leave a *doré* (gold and silver alloy) bead.

4. Weighing: the weight of the *doré* bead is reported as gold plus silver.

5. Parting: treating the *doré* bead with hot dilute nitric acid to dissolve the silver.

6. Weighing: the residual gold is weighed on a delicate balance and reported as gold. The weight of silver is obtained by calculating the difference between this weight and the weight of the *doré* bead.

Sampling.—Samples are customarily dried and pulverized to a size that will pass through a 100-mesh sieve before the assay portion is taken. At this particle size an assay portion of one-tenth to two assay tons may compose a sufficiently reliable sample. For the same reliability, the assay portion of the pulverized ores must vary with the degree of uniformity of the ore particles. When the values are finely divided and uniformly distributed, small assay portions can be used with a saving of reagents. Pulverized ores containing relatively large, rich particles require larger assay portions. Some ores contain rich malleable particles which are larger than 100-mesh. Such ores require an assay portion of a kilogram or more which is handled by a "metallics assay." In the metallics assay the large assay portion is weighed and then carefully crushed in stages with repeated screening to separate the malleable particles. Finally a "metallics portion" is obtained which contains the malleable particles, and the bulk of the sample has been pulverized to pass a 100-mesh sieve. All of the metallics portion is put through an assay process to recover its gold and silver, and the minus 100-mesh material is sampled and assayed in the usual way. The gold and silver content of the ore is calculated from the results of the two assays.

Fusion.—In assay fusion the assay portion of ore is heated with reagents in such a manner that the ore is decomposed and formed into a fusible slag while the precious metals are released and dissolved in molten lead. Lead is supplied in the form of lead oxide (litharge) in the crucible process and as granulated lead in the scorification (reduction to slag) process.

The crucible process takes place in a clay crucible. It is a reducing fusion in which a part of the litharge in the charge is reduced to metallic lead. Reduction is brought about by reducing agents such as flour or charcoal added to the charge or by sulfide minerals in the ore. Some ores possess too much reducing power and require the addition of an oxidizing reagent such as nitre. The objective is to produce about 25 g. of lead and to leave as a flux an amount of litharge at least equal to the weight of the assay portion of ore. Other fluxes such as soda ash and borax glass are commonly used to help decompose the ore and to increase the fluidity of the slag. Crucible fusions are effected at a temperature slightly over 1,000° C. in muffle furnaces, in which the charge is separated from the combustion chamber by a closed vessel, or oven. After the reactions have been completed the fluid contents of the crucibles are poured into conical iron molds and allowed to solidify. The slag is then broken and the lead buttons are hammered to free them from the slag and to produce a cubical shape for easy handling.

The scorification process is not often used because it cannot conveniently handle as large an assay portion of ore as is generally necessary. The maximum weight of ore ordinarily handled by scorification is 0.2 assay ton. The assay portion is charged into a shallow fire-clay dish with granulated lead and a little borax glass. The scorifying dish and its charge are then placed in a muffle furnace at about 600° C. After the lead has melted the muffle door is opened to provide air for oxidation and the temperature is gradually raised to approximately 1,000° C. The molten lead oxidizes and the lead oxide fluxes the ore. Finally the ore is decomposed and a fluid slag is formed which covers the remaining lead. At this stage action has stopped and about 25 g. of lead should be left unoxidized. The scorifying dish is withdrawn from the furnace and the contents poured into an iron mold as in the crucible process.

Cupellation.—Lead buttons containing the gold and silver from assay fusions are treated by cupellation to recover the precious metals. Cupellation is an oxidizing fusion in a small porous vessel known as a cupel. During cupellation the lead is oxidized to litharge which is mostly absorbed by the cupel. The temperature must be low to avoid excessive loss of silver but it must also be above the melting point of litharge. At the end of the process a *doré* bead containing the gold, silver and most of the platinum that may have been present in the ore is left in the bowl of the cupel.

Weighing and Parting.—The *doré* bead is squeezed with pliers and brushed to remove adhering material from the cupel. It is then weighed. This weight represents the weight of the combined precious metals. Silver is then removed by parting (dissolving) in hot dilute nitric acid. The residual gold is washed, dried, annealed and weighed. *Doré* beads containing less than two times as much silver as gold will not part. Such beads are melted with additional silver, a process called inquartation, before parting.

ASSAYING ORES FOR PLATINUM METALS

The platinum metals present in an ore are collected in the lead button of an ordinary fire-assay crucible fusion or scorification. Platinum, palladium and rhodium dissolve in the molten lead and are collected in the same manner as gold and silver. Osmium, iridium and ruthenium do not alloy with the lead but are "wetted" by it in the assay fusion: they sink into the lead and are mechanically held at the bottom of the lead button.

Cupellation of lead buttons containing more than 15 times as much gold and silver as platinum metals proceeds normally. Platinum, palladium and rhodium alloy with the gold and silver and are satisfactorily recovered in the final bead. Platinum causes a roughening of the surface of silver beads, giving them a characteristic frosted appearance. Iridium does not alloy with the gold and silver; when present during cupellation it forms a black deposit that clings to the bottom of the bead. Osmium and ruthenium form volatile oxides when heated in air and consequently they suffer a large loss during cupellation. When these metals are present cupellation should be avoided and the lead button should be analyzed by wet chemical methods.

The nitric acid parting treatment given *doré* silver beads during the assay for gold and silver will dissolve palladium and part of the platinum. To avoid reporting these metals as silver, the spent acid should be watched for indications of platinum and palladium. Palladium produces a yellow colour in the acid. Platinum dissolves only when the bead contains more than ten times as much silver as platinum. A considerable amount of platinum gives the spent acid a dark brown colour like a colloidal solution of carbon. Rhodium, iridium, osmiridium and some platinum remain with the gold during parting and give it a "not completely parted" appearance. When platinum metals are present, either the lead button or the *doré* bead should be treated by wet chemical methods for the determination of the separate platinum metals.

FIRE ASSAYING FOR BASE METALS

Fire-assaying methods have been used for the determination of the easily reducible base metals such as lead, bismuth, tin, antimony and copper. In order to determine one of these metals by fire methods a five- or ten-gram assay portion of the ore is mixed with fluxes and an excess of reducing agent in a crucible. The crucible is heated in a furnace to produce a button of the reduced metal and a fusible slag. The button is weighed to determine the amount of metal. Results tend to be low because of loss of metal and tend to be high due to reduction of impurities. Wet chemical analytical procedures give greater precision and have almost completely supplanted fire-assaying methods for the determination of the base metals.

For information on chemical analytical procedures *see* CHEMISTRY: *Analytical Chemistry*.

ASSAY OFFICE, a place where samples of metals and ores are tested to determine what quantity of the various metals are

present in them. The term assay office was first generally applied to offices established by the United States in various locations as part of the government mint service to purchase newly mined gold and silver and to assay samples of bullion and ores. There are two U.S. assay offices, one in New York city and the other in San Francisco, Calif. The latter, known as the San Francisco mint, discontinued coinage operations in 1955.

The assay offices receive deposits, assay, process, and store gold and silver bullion. The New York office maintains an electrolytic refinery for refining gold and silver. It has special facilities for assaying metals in the platinum group and also receives and issues gold bars for the settlement of international balances. Both the New York and San Francisco offices sell gold and silver bars for industrial, professional and artistic use. Two other U.S. mints, in Philadelphia, Pa., and Denver, Colo., also handle gold and silver.

A special Assay commission meets at the Philadelphia mint once a year to examine and test U.S. silver coins.

The assay offices, bullion depositories and mints comprise the bureau of the mint, which is a part of the treasury department. *See* also ASSAYING; MINT. (L. HD.)

ASSEMANI, the name of a Syrian Maronite family of orientalists.

JOSEPH SIMONIUS (1687–1768), from Mt. Lebanon, studied at the Maronite college in Rome and then entered the Vatican library. Having been sent to Egypt and Syria in 1715 in search of manuscripts he secured about 150 select specimens. This success induced the pope to send him again in 1735 and a still more valuable collection was acquired. On his return he was created titular archbishop of Tyre and librarian of the Vatican library. His chief work is his *Bibliotheca Orientalis,* a treasure store for later scholars. This was intended to cover in four parts manuscripts in Greek and a number of oriental languages, but only the Syriac in three volumes appeared: *De Scriptoribus Syris Orthodoxis* (1719); *De Scr. Syr. Monophysitis* (1721); and *De Scr. Syr. Nestorianis* (1725–28). With his nephew, Stephen Evodius (*see* below), Simonius published *Bibliothecae Apostolicae Vaticanae Codicum Manuscriptorum Catalogus* (1756–59). This was reproduced photographically in Paris in 1927–30. He also produced the first three volumes, the Greek texts, of *Ephraemi Syri Opera Omnia . . . in sex tomos distributa* (1732–46).

His nephew, JOSEPH ALOYSIUS (*c.* 1710–82), was professor of oriental languages at Rome. STEPHEN EVODIUS (1707–82), titular archbishop of Apamea in Syria and holder of several ecclesiastical preferments in Italy, assisted his uncle, Joseph Simonius, in the Vatican library and collaborated in producing its catalogue. His chief works are *Bibl. Mediceae Laurentianae et Palatinae Codd. Mss. Oriental Catalogus* (1742) and *Acta SS. Martyrum* (1748). SIMON (1752–1821), grandnephew of Joseph Simonius, was professor of oriental languages at Padua. (W. D. McH.)

ASSEMBLIES OF GOD, a religious sect in the United States belonging to the so-called Pentecostal group, was formed by a union of several small bodies at Hot Springs, Ark., in 1914. In 1916 its headquarters were established at Springfield, Mo., and it was incorporated under the name of the General Council of the Assemblies of God.

It is the largest of all the numerous Pentecostal bodies in the country, having more than 8,000 local churches and pastors and more than 500,000 members, with a dozen administrative boards and several publications issued by its central publishing house.

In doctrine the Assemblies of God is conservative, embracing the so-called Fundamentalist theology. It teaches entire sanctification but differs from similar churches in that it does not insist that this is a second work of grace subsequent to justification or conversion but recognizes the progressive character of the experience.

The distinctive feature of the doctrines and practices of the Assemblies of God is that of the glossolalia, or "speaking in other tongues as the Spirit gives utterance." (*See* TONGUES, GIFT OF.) This is regarded as the climactic experience of the religious life and is bestowed upon believers instantaneously following the attainment of holiness or perfection. It derives from the phenomenon on the Day of Pentecost as recorded in Acts ii, 1–13.

See Elmer T. Clark, *The Small Sects in America* (1949); Charles W. Conn, *Like a Mighty Army* (1955); *The Church of God* (periodical published at Queens Village, N.Y.). (E. T. CL.)

ASSEMBLY, RIGHT OF, the privilege of individuals to meet together for such purposes as deliberation, worship or the expression of grievances.

Assembly to discuss grievances poses a dilemma for every government which aspires both to freedom of the citizen and to order in society. Angry crowds can seriously trouble many, partisans and nonparticipants alike; but liberty to meet and debate grievances is basic in a reasonably free society. Essential to reconciliation of these conflicting tensions are not only wise constitutional and statutory guarantees, enforced by independent and courageous judges; even more essential is an enlightened policing system.

England approached this problem by forbidding disorderly gatherings rather than by guaranteeing free assembly. A statute of 1661 forbade presentation of petitions to king or parliament by more than ten persons at a time (13 Car. 2, c. 5). The English Bill of Rights of 1689 omitted assembly but guaranteed the right to petition the king (1 Will.-Mary, sess. 2, c. 2). Across the Atlantic, however, the First Continental Congress on Oct. 14, 1774, proclaimed the colonists' right to assemble and petition the king. Seventeen years later the first amendment to the then three-year-old constitution forbade the congress to abridge ". . . the right of the people peaceably to assemble, and to petition the Government for a redress of grievances."

Almost all state constitutions in the United States contain similar guarantees; and the U.S. supreme court has held that even when a state constitution fails to assure a reasonable right of assembly the 14th amendment of the federal constitution guarantees against unreasonable state restriction (*De Jonge* v. *Oregon,* 299 U.S. 353 [1937]). There are difficult problems in applying this guarantee, however. Often assemblies arouse their adversaries to violent objection; police sometimes find it easier to stop the meeting than to suppress the disorderly opponents. The supreme court has indicated that police cannot thus be used as an instrument to suppress unpopular views, but when a public speaker attracts a crowd which blocks traffic, or when he passes the bounds of argument or persuasion and incites to riot, the police may constitutionally arrest him (*Feiner* v. *New York,* 340 U.S. 315 [1951]). Where the meeting is held indoors, violent opposition from outside furnishes less justification for police interference with the meeting (*Terminiello* v. *Chicago,* 337 U.S. 1 [1949]).

Another administrative problem arises from competition for public space. A state or city, as proprietor of its parks, was once held constitutionally empowered to forbid all meetings there (*Davis* v. *Massachusetts,* 167 U.S. 43 [1897]). This is probably not law today, but a state may enforce reasonable requirements for permits in order to prevent unseemly clashes between groups which attempt to meet at the same time (*Poulos* v. *New Hampshire,* 345 U.S. 395 [1953]). An official may not constitutionally be entrusted with discretion to grant or deny a permit as he sees fit, with no standards to guide his judgment (*Kunz* v. *New York,* 340 U.S. 290 [1951]). And functionaries empowered to grant permits for park meetings may not constitutionally play favourites between groups (*Fowler* v. *Rhode Island,* 345 U.S. 67 [1953]). An assembly to plan or carry out a crime is not privileged.

Judicial protection of the right of assembly is inevitably slow. The Committee for Industrial Organization, forbidden by Mayor Frank Hague in Nov. 1937 to hold a public meeting in Jersey City, N.J., sued the mayor and other officials. The supreme court of the United States finally decided in favour of the committee's right to hold the meeting, but not until June 1939 (*Hague* v. *Committee for Industrial Organization,* 307 U.S. 496 [1939]). In many cases far less delay would frustrate the purpose of the meeting. An effective right of assembly really depends on wise and tolerant police, willing to allow meetings unless impending violence is clearly apparent. The English have provided a proverbial example of such tolerance in Hyde Park, London. (*See* also BILL OF RIGHTS, UNITED STATES.) (A. E. SU.)

English Law.—As suggested above, in English law the best ap-

proach to the question of the right of assembly is to find out what types of assembly are unlawful and in what circumstances. J. F. Archbold's *Criminal Pleading, Evidence and Practice*, 34th ed. (1959), p. 1335, defines an unlawful assembly at common law as "an assembly of three or more persons (*a*) for purposes forbidden by law, such as that of committing a crime by open force; or (*b*) with intent to carry out any common purpose, lawful or unlawful, in such a manner as to endanger the public peace, or to give . . . reasonable grounds to apprehend a breach of the peace in consequence of it." Riots are punishable both by common law and under the Riot act, 1714, while a rout (an assembly which gathers for the purpose of rioting and which makes a move towards the commission of its purpose) is another example of an unlawful meeting. In some parts of the Commonwealth and colonies particular emergencies have from time to time led to a suspension of the right of assembly.

ASSEMBLY LINE: *see* MASS PRODUCTION.

ASSEN, a town in the northern Netherlands, capital of the province of Drenthe, lies 16 mi. S. of Groningen. Pop. (1957 est.) 27,041. Situated amid wooded surroundings, Assen has three parks, including one where children learn traffic regulations, and a museum of antiquities. The main electric railway from Amsterdam to Scandinavia, and the main road linking with Stockholm pass through the town. Eelde airport is 10 mi. north. Assen was founded in 1257 around the site of a small convent. It has some light industry and is scheduled by the government as an area for industrial development.

ASSENS, a county council district (*amtsrådskreds*) of southern Denmark, covers the northwest of Fyn (Fünen) Island. Pop. (1955) 58,005. Area 257 sq.mi. Its fertile loams grow good crops of barley, oats, wheat, rye and roots. Dairying and pig-rearing are traditional. The district is centred on the port of Assens (pop., 5,012) which has sugar and bacon factories. At Middelfart (pop., 8,883), a port connected to Jutland by the Little Belt bridge, there are porcelain and metal industries and market gardening flourishes in the surrounding district. (HA. T.)

ASSER (d. *c.* 909), Welsh monk, chiefly remembered as the friend, teacher, counselor and biographer of Alfred the Great (*q.v.*), was born in Wales and became a monk at St. David's abbey, Pembrokeshire. In 886, eager to learn Latin, Alfred summoned Asser, who had acquired some reputation for learning, to his court in Wessex, and on St. Martin's Day (Nov. 11), 887, as Asser himself tells us, the Latin lessons began. Thereafter Asser divided his time between the court and his own community, and became Alfred's friend as well as his teacher. The king made him abbot of the monasteries of Congresbury and Banwell, Somerset, and later appointed him bishop of the diocese of Devon and Cornwall. At the time of his death (recorded as being in 909) he was bishop of Sherborne, Dorset.

Asser's *Life of King Alfred* follows Alfred's career from his birth to his accession in 871, and describes in detail his reign and his wars, stopping abruptly in 887, 12 years before Alfred's death. As an account of historical events, it draws largely on the *Anglo-Saxon Chronicle*, but it adds much information on Alfred's care for his army, his fleet, his cities and their houses, his lawcourts, his enthusiasm for learning and for the spread of education, and his piety. It is naïve, and overfull of enthusiasm, carelessly constructed and sometimes hard to follow, but it is an indispensable source. Scholars have suggested that, in whole or in part, it is not the work of Asser, but this view has not been widely accepted.

BIBLIOGRAPHY.—The first edition of Asser's life of Alfred (1574), contained grievous interpolations by Archbishop Matthew Parker. It was excellently edited by W. H. Stevenson (1904); edition reissued in 1959, with much additional material by Dorothy Whitelock. Asser's authorship is held doubtful by J. W. Adamson, *The Illiterate Anglo-Saxon* (1946); V. H. Galbraith, *Historical Research in Medieval England* (1951). There is an English translation by L. C. Jane (1924).
(E. S. DT.)

ASSER, TOBIAS MICHAEL CAREL (1838–1913), Dutch jurist, who shared the Nobel peace prize in 1911 with Alfred H. Fried, was born at Amsterdam, Neth., on April 28, 1838. In 1862 he became professor of commercial and private international law in the University of Amsterdam, being at the same time a successful barrister. In 1868, with John Westlake and Rolin Jacquemijns, he started the *Revue de droit international et de législation comparée*. He was also one of the founders of the Institut de Droit International in 1873.

In 1891 Asser prevailed upon the Dutch government to convoke the Hague Conference for the Unification of International Private Law, which first met in 1892 and later became a permanent institution, responsible, among other things, for the Hague treaties of 1902–05 concerning family law. In 1911–12 he presided over conferences for the unification of the law relating to bills of exchange. In 1893 he resigned his professorship and retired from his law practice, becoming a member of the *raad van state* (privy council). Asser was a Netherlands delegate to the Hague peace conferences of 1899 and 1907. His greatest success at the first conference was the organization of the Permanent Court of Arbitration. He died on July 29, 1913. (GD. E. L.)

ASSESSED VALUATION: *see* VALUATION.

ASSESSMENT, a demand or call made by a corporation upon stockholders for a specified sum of money per share of stock in addition to that already paid in. Such assessments are generally made when the company is financially embarrassed and it is a question of the stockholders meeting the assessment or the company becoming insolvent. Reorganizations of corporations frequently involve the placing of an assessment on the stockholders and sometimes even upon bondholders. *See* JUDICIARY AND COURT OFFICERS; VALUATION.

ASSESSOR, in the United States, an official who evaluates property for purposes of taxation. An assessor exists as a county officer in virtually all the states, and is elected by the voters for a term of two, three or four years. Originally, in the early colonial days, the work of the assessor was done by justices of the peace and was transferred in later colonial days to county boards of commissioners or supervisors. The duties of the assessor are generally to list all property and persons subject to taxation and to determine the value of property to be taxed. Appeals are provided by statutes to county boards of commissioners or supervisors or courts where the person taxed may protest against the amount assessed as being unfair. Some states have provided for township assessors, elected by the voters of the township, to work under the supervision of the assessor, and in others the assessor is permitted a sufficient number of deputies to aid him in the completion of his work, the assessments generally being made annually. Most of the states have state boards of taxation which supervise, to some extent, the work of the assessors. In most of the states this board is named by the governor, but in a few, such as Illinois, where it is called the board of equalization, it is elected.

In Roman law, used throughout Europe, wherever the civil law system is prevalent, an assessor is one who is called by the courts to give legal advice and assistance. In the United States federal district courts experienced shipmasters serve as assessors in this sense of the word in admiralty matters.

See also JUDICIARY AND COURT OFFICERS; VALUATION: *Taxation*. (S. LE.)

ASSIGNATS, the paper currency notes issued during the French Revolution period on the security of property belonging to the French nation.

The financial crisis that had brought about the summoning of the estates-general in 1789 (*see* FRANCE: *History*; FRENCH REVOLUTION) obliged the constituent assembly first to put ecclesiastical property "at the disposition of the nation" (Nov. 2, 1789) and

then to establish an "extraordinary fund" for the purpose of raising 400,000,000 livres (francs) by means of assignats on this property and on crown lands (Dec. 19). The assignat was thus a certificate of debt, a sort of treasury bond bearing interest at 5%, entitling the holder to repayment in property to the value of the assignat. The intention was that, as the transfer of the property was effected, the assignats would be returned and canceled and the national debt thus paid off. The operation, however, did not succeed, as the assignats were not taken up very readily (the clergy was still in occupation of its property, and the ecclesiastical reform had not yet taken place). The state's need for ready money remained constant, however, so that on Aug. 27, 1790, a crucial change was made: it was decided that the assignats should no longer bear interest. This turned the assignats from bonds into a paper currency, equivalent to banknotes. At the same time the issue was increased to 1,200,000,000 livres, despite grave warnings of the risk of inflation.

The change had political and social as well as financial consequences. Whereas the original assignats transferred property only to creditors of the state (financiers, contractors, persons entitled to compensation for loss of office as a result of administrative reforms), the assignats as currency might come into anyone's hands. Then, as more and more were issued, the assignats depreciated rapidly, particularly as the partisans of the former regime declared that if they were restored to power they would not recognize the currency of the Revolution. When the assembly itself authorized dealing in coin, there was little to check this depreciation; coin was hoarded and silver money went out of circulation. Finally, after long hesitation, the assembly even issued assignats of small denominations (assignat of five livres, 1791). Thereupon the price of commodities and the cost of living rose (higher prices were charged when payment was in assignats than when it was in coin), and unrest ensued. Even so, the consequences of the currency assignat were not altogether disastrous. In its beginnings, it revived the economy, ended unemployment and served to reduce the rate of foreign exchange (exporters, paid abroad in coin and paying to their workers at home wages which were only slowly rising, were especially benefited by it).

The outbreak of war in April 1792 was necessarily followed by more issues of notes, and inflation brought with it the eventual failure of the assignat. In Jan. 1793, it still stood at 60%–65% of its nominal value; the next month, it went down to 50%; and in July it stood at less than 30%. Capital went abroad, speculation increased, merchandise was hoarded and prices continued to rise. Pierre Joseph Cambon (*q.v.*), the financial expert of the Convention, now devoted himself to checking inflation and, on July 31, 1793, demonetized all royal, *i.e.*, pre-republican, assignats of more than 100 livres in nominal value. Price control, instituted by the *loi du maximum général* (Sept. 29, 1793), was more effective, and in December the assignat rose again to 50% of its nominal value. On Dec. 26, Cambon requisitioned all foreign bills and paid for them, at par, in assignats.

In the summer of 1794 inflation, which had been halted for a time, began again, and in the Seine *département* the assignat went down to 34% of its nominal value. The situation deteriorated further after the Thermidorian reaction, when the abandonment of the guided economy of the previous 12 months brought catastrophe. Prices soared, foreign exchange collapsed, and the state had to resign itself to large-scale inflation. In July 1795 the assignat was worth barely 3% of its face value. Tradespeople and peasants refused it and would no longer accept anything but coin. On June 21, 1795, the Convention reduced the nominal value of the assignat according to a proportional scale related to the successive issues. On July 20, moreover, it ordered that half the amounts due under the land tax and for farm rents should be paid in kind. It also granted to officials—the principal victims of the depreciation of the paper currency—a sliding salary scale calculated on the price of bread. Then, as salaries could no longer follow the steep rise in prices, purchasing power was correspondingly reduced and numerous businesses were forced to close. Famine aggravated the situation, and the Parisian sans-culottes rose twice in revolt (April and May, 1795). When price control (as under the *loi du maximum général*) was abolished (Dec. 24, 1794), the paper money in circulation was estimated at 8,000,000,000 livres; and on Oct. 23, 1795, three days before the dissolution of the Convention, it was assessed at 20,000,000,000.

When the Directory was established, inflation reached its highest point: the assignat of 100 francs was worth only 15 sous. The sale of national property was suspended, and in order to save creditors from ruin, a moratorium was declared. Within four months, issues had risen, reaching the nominal value of 39,000,000,000 francs: in the course of a night money was being printed for the morrow's expenditure. On Feb. 19, 1796, pretenses could no longer be kept up, and the assignat was abandoned.

There could be no question, however, of returning to a metal currency. The circulation of coin was then estimated at about 300,000,000—as against at least 2,000,000,000 livres in 1789. Accordingly, on March 18, 1796, a new paper currency was issued in the form of *mandats territoriaux* ("land warrants"), valid for the acquisition of national property, of which 2,400,000,000 francs' worth were issued. Of these 600,000,000 were to serve for repayment of the assignats at the rate of 30 assignats for 1 *mandat*; the rest would go to the treasury. The public, however, had no confidence in the *mandats*, which by July 1796 were no longer being taken up. The Directory then decided to return to a metallic currency. The law of 16 Pluviôse year V (Feb. 4, 1797), withdrew the *mandats* from circulation. Thus ended the history of the paper currency of the Revolution.

The social consequences of the issue of assignats were far-reaching. Inflation dealt a heavy blow to acquired wealth. During 1794–95 debtors hastened to redeem their debts cheaply and on July 11, 1795, the Convention was obliged to forbid the repayment of loans made before July 1, 1792, and the discharge of subsequent ones before they fell due. The old bourgeoisie of *rentiers* and office-holders, in so far as it was the state's principal creditor was ruined by the inflation, with the result that many of its members transferred their sympathies to the enemies of the Revolution. On the other hand the fluctuation of the currency brought into being a new bourgeoisie of successful speculators, who took advantage of it to enrich themselves to the detriment of the national assets and without benefit to the community.

Bibliography.—R. Stourm, *Les Finances de l'ancien régime et de la Révolution* (1885); C. Gomel, *Histoire financière de l'Assemblée constituante*, 2 vol. (1896–97); M. Marion, *Histoire financière de la France depuis 1715*, vol. ii (1919); J. Morini-Comby, *Les Assignats* (1925); S. E. Harris, *The Assignats* (1930). (A. So.)

ASSIGNMENT, in law, denotes a transfer of rights, particularly with reference to intangible property, whether or not evidenced by a specialty, such as an insurance policy or a certificate of corporate shares. For the assignment of the property of a debtor for the benefit of creditors, *see* Bankruptcy; Debtor and Creditor Law. (J. A. MacL.)

ASSINIBOIA, a name formerly applied to three districts in western Canada. (1) The grant made by the Hudson's Bay company to Lord Selkirk in 1811 for his Red River settlement (*q.v.*) which included all southern Manitoba and also the Red river valley in North Dakota and Minnesota. (2) When the Selkirk grant was resumed by the Hudson's Bay company, the "District of Assiniboia" was organized in 1835. Comprising the area within a radius of 50 mi. from Fort Garry, it was administered by a local governor and council appointed by the company until it was ended by the formation of Manitoba in 1870 (*see* Manitoba: *History*). (3) In 1882 the federal district of Assiniboia was created as a part of the old Northwest Territories to extend from the boundary of Manitoba westward to the district of Alberta along the international boundary and south of the district of Saskatchewan. In 1905 about one-fifth of Assiniboia was absorbed by Alberta and the rest became part of Saskatchewan.

The original district had as its centre the valley of the Assiniboine river, a tributary of the Red, and the name was formed from that of the river and the Assiniboin Indians. (W. L. Mo.)

ASSINIBOIN, an American Indian Plains tribe who split from the Yanktonai Sioux before the 17th century and were known to the early French and English traders after 1640 as allies of the Algonkian Cree with whom they lived in the area west of Lake

Winnipeg. Over a period of 150 years, the Assiniboin gradually moved westward and southward. A few bands remained in Canada where they still continued to be known as Stonies, while the remainder settled near the junction of the Missouri and Yellowstone rivers. Although restricted in their movements after 1851, they were not placed on reservations until 1884. They are still dependent upon government for a good part of their subsistence and are more disorganized, poorer and less educated than their non-Indian neighbours. In the 1960s the Assiniboin numbered more than 1,000 in Canada (concentrated in Alberta), and were reported to exceed 4,000 in the U.S. (most of them sharing lands on the Fort Belknap and Fort Peck reservations in Montana with other tribes). Less than one-fourth of the Montana Assiniboin can be considered full-bloods; the others are mixed with white, Yanktonai Sioux, Cree and Gros Ventre.

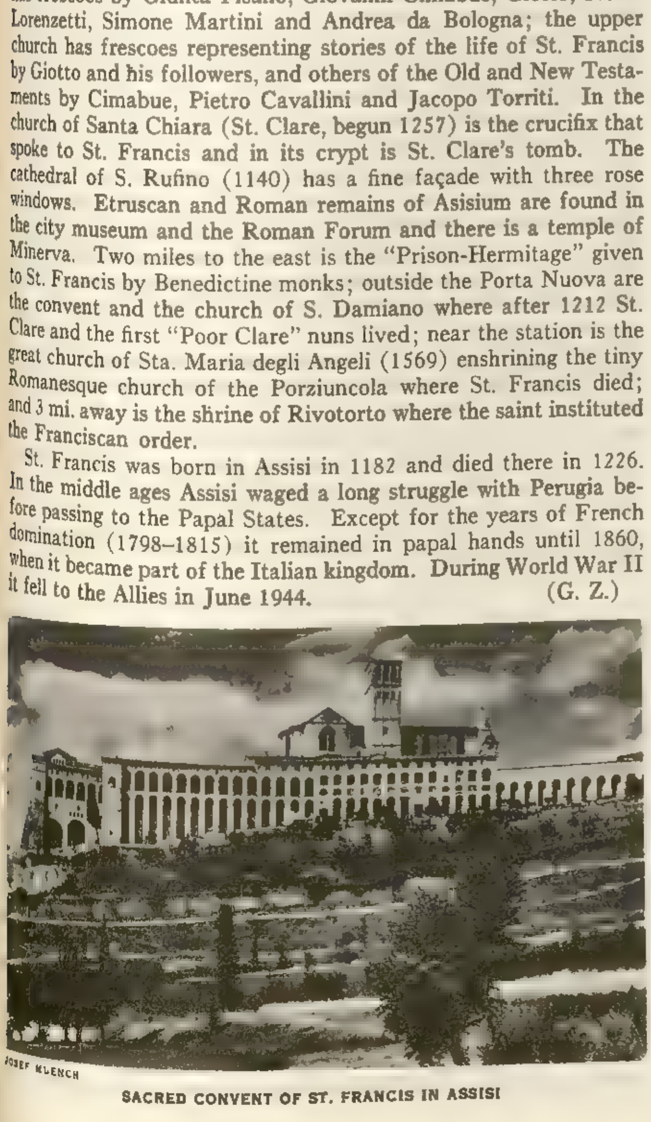
ASSISI, birthplace of St. Francis, is a city of the region of Umbria and province of Perugia in central Italy standing on a hill, 1,300 ft. high, above the valleys of the Topino and Chiascio 16 mi. by road east-southeast of Perugia. Pop. (1961) 25,373 (commune). The town, with its narrow winding streets, is surrounded by walls. The chief feature is the Romano-Gothic Sacred Convent of St. Francis with its upper and lower churches, begun immediately after the canonization of St. Francis in 1228 and completed in 1253. The crypt was added in 1818, when the tomb of St. Francis was opened. The saint is buried in the lower church which has frescoes by Giunta Pisano, Giovanni Cimabue, Giotto, Pietro Lorenzetti, Simone Martini and Andrea da Bologna; the upper church has frescoes representing stories of the life of St. Francis by Giotto and his followers, and others of the Old and New Testaments by Cimabue, Pietro Cavallini and Jacopo Torriti. In the church of Santa Chiara (St. Clare, begun 1257) is the crucifix that spoke to St. Francis and in its crypt is St. Clare's tomb. The cathedral of S. Rufino (1140) has a fine façade with three rose windows. Etruscan and Roman remains of Asisium are found in the city museum and the Roman Forum and there is a temple of Minerva. Two miles to the east is the "Prison-Hermitage" given to St. Francis by Benedictine monks; outside the Porta Nuova are the convent and the church of S. Damiano where after 1212 St. Clare and the first "Poor Clare" nuns lived; near the station is the great church of Sta. Maria degli Angeli (1569) enshrining the tiny Romanesque church of the Porziuncola where St. Francis died; and 3 mi. away is the shrine of Rivotorto where the saint instituted the Franciscan order.

St. Francis was born in Assisi in 1182 and died there in 1226. In the middle ages Assisi waged a long struggle with Perugia before passing to the Papal States. Except for the years of French domination (1798–1815) it remained in papal hands until 1860, when it became part of the Italian kingdom. During World War II it fell to the Allies in June 1944. (G. Z.)



JOSEF KLENCH

SACRED CONVENT OF ST. FRANCIS IN ASSISI

ASSIZE (ASSISE), a legal term meaning literally a "session," but in fact sometimes a jury, the sittings of a court, or the ordinances of a court or assembly.

It originally signified the form of trial by a jury of 16 persons, which eventually superseded the barbarous judicial combat; this jury was named the grand assize and was sworn to determine the right of seisin of land (*see* EVIDENCE). The grand assize was abolished in 1833; but the term assize is still applicable to the jury in criminal causes in Scotland.

In the only sense in which the word is not now almost obsolete, assize means the periodical session of the judges of the high court of justice held in the various counties of England, chiefly for the purposes of trying jailed prisoners and causes at nisi prius. Previous to Magna Carta (1215) all writs of assize had to be tried at Westminster, or to await trial in the locality in which they had originated at the septennial circuit of the justices in eyre; but, by way of remedy for the great consequent delay and inconvenience, it was provided by this celebrated act that the assizes of *mort d'ancestor* and novel disseizin should be tried annually by the judges in every county. By successive enactments, the civil jurisdiction of the justices of assize was extended, and the number of their sittings increased, until at last the necessity of repairing to Westminster for judgment in civil actions was almost obviated to country litigants by an act, passed in the reign of Edward I, which provided that the writ summoning the jury to Westminster should also appoint a time and place for hearing such causes within the county of their origin. The date of the alternative summons to Westminster was always subsequent to the former date, and so timed as to fall in the vacation preceding the Westminster term, and thus *"Unless before,"* or nisi prius, issues came to be dealt with by the judges of assize before the summons to Westminster could take effect. The nisi prius clause, however, was not then introduced for the first time. It occurs occasionally in writs of the reign of Henry III. The royal commissions to hold the assizes are (1) general, (2) special. The general commission is issued twice a year to the judges of the high court of justice, and two judges are generally sent on each circuit. It covers commissions (1) of oyer and terminer (*q.v.*), by which they are empowered to deal with treasons, murders, felonies, etc.; this is their largest commission; (2) of nisi prius; (3) of jail delivery, which requires them to try every prisoner in jail, for whatever offense committed; (4) of the peace, by which all justices must be present at their county assizes or else suffer a fine. Special commissions are granted for inquest in certain causes and crimes (*see* COURT; PRACTICE AND PROCEDURE).

Assizes, in the sense of ordinances or enactments of a court or council of state, as the "assize of bread and ale," the "assize of Clarendon," the "assize of arms," are important in early economic history. As early as the reign of John the observance of the *Assisae venalium* was enforced, and for a period of 500 years thereafter it was considered no unimportant part of the duties of the legislature to regulate by fixed prices the sale of bread, ale, fuel, etc. The word assize is used in a wider legislative connection by early chroniclers and historians—the "assisae of the realme," *e.g.*, occasionally meaning the organic laws of the country. For the "assizes of Jerusalem" *see* CRUSADES: *Organization of the Latin States.*

The term assize, originally applying to an assembly or court, became transferred to actions before the court of the writs by which they were instituted. The following are the more important.

Assize of darrein presentment, or last presentation, was a writ directed to the sheriff to summon an assize or jury to inquire who was the last patron that presented to a church then vacant, of which the plaintiff complained that he was deforced or unlawfully deprived by the defendant. It was abolished in 1833 and the action of *quare impedit* substituted. But by the Common Law Procedure act, 1860, no *quare impedit* can be brought, so that an action in the king's bench of the high court was substituted for it.

Assize of *mort d'ancestor* was a writ which lay where a plaintiff complained of an "abatement" or entry upon his freehold, effected by a stranger on the death of the plaintiff's father, mother,

brother, sister, uncle, aunt, etc. It was abolished in 1833.

Assize of novel disseizin was an action to recover lands of which the plaintiff had been "disseised" or dispossessed. It was also abolished in 1833.

Assize, clerk of, an officer "who writes all things judicially done by the justices of assizes in their circuits." He has charge of the commission and takes recognizances, records, judgments and sentences, grants certificates of conviction, draws up orders, etc. By the Clerks of Assize act, 1869, he must either have been for three years a barrister or solicitor in actual practice, or have acted for three years in the capacity of subordinate officer of a clerk of assize on circuit.

ASSOCIATION, CHEMICAL. Association is a term used in a specialized sense in chemistry to denote the aggregation of atoms or molecules into larger units, the forces holding these units together being weaker than those involved in the formation of ordinary chemical bonds. The term is usually restricted to the formation of aggregates of like atoms or molecules. Polymerization (*q.v.*) also refers to the formation of large units by the union of like small units. A molecular aggregate formed by association is a polymer in which the forces holding the smaller units together are relatively weak. Association is thus a special case of polymerization. It is difficult or impossible to draw a sharp dividing line between association and other types of polymerization. In general, however, a polymerization which is not an association involves the formation of ordinary chemical bonds between the smaller units (monomers), whereas in mere association of molecules they are held together by weaker forces. Because of the qualitative difference between the strengths of the forces holding the small units together an equilibrium is often observed between an association complex and the corresponding simple molecules, whereas such an equilibrium is rarely found, except at quite high temperatures, between a polymer of the chemical bond type and its monomer. An equilibrium mixture of an association complex and the corresponding small molecules behaves chemically in much the same manner as would the small molecules by themselves, since the removal of some of the small molecules by chemical reaction shifts the equilibrium in such a way as to dissociate more of the aggregate, in accordance with the law of mass action (*see* REACTION KINETICS; PHASE EQUILIBRIA). Many physical properties (for instance, the density of a gas at a given temperature and pressure) depend on the number and average size of the independently moving units and thus on the number of molecules in each aggregate and the relative numbers of simple molecules and aggregates under the conditions of the experiment (*see* STOICHIOMETRY). For these reasons, much of the information regarding the existence of aggregates has come from studies of these physical properties, rather than from chemical studies. In some cases, X-ray diffraction (*see* CRYSTALLOGRAPHY: *Crystal-Structure Analysis*) and electron diffraction studies confirmed the conclusions arrived at in this way and, in addition, supplied detailed knowledge of the relative positions of the atoms in the aggregates.

Forces Producing Association.—The types of forces tending to make like molecules associate may be briefly considered. Most important are the forces of "hydrogen bond" (or "hydrogen bridge") formation, in which a hydrogen atom, bonded to an electronegative atom (*e.g.*, oxygen), forms a bridge to another electronegative atom. If these two electronegative atoms are in different molecules, the formation of the bridge unites the two. The energy required to break a hydrogen bond is of the order of 5 to 10 kg.cal. per mole; *i.e.*, about one-tenth that needed to break an average chemical bond in an organic compound. This is still much greater than the average energy per molecule at ordinary temperatures; hence, association complexes in which the component molecules are held together by hydrogen bonds are not readily broken up by molecular collision except at higher temperatures.

Molecules may also be held together, if the temperature is not too high, by dipolar attraction, resulting from the separation of positive and negative charges in each molecule. The molecule as a whole may be polar, one end having an excess positive charge and the other an excess negative charge, or it may contain polar groups. In either case it tends to orient and attract another similar molecule in the vicinity. If the attraction energy is large enough, relative to the average kinetic energy (see *Association in Gases,* below), association occurs.

Still weaker, in general, are the so-called London dispersion forces which act between any two atoms which are close together. These may be explained in the following way: an atom consists of a heavy, positively charged nucleus, surrounded by a cloud of (rotating) negatively charged electrons. The negative electron cloud may oscillate with respect to the positive nucleus. The atom can then be described as an oscillating dipole, changing polarity with each oscillation. Two neighbouring atoms tend to oscillate in synchronism with each other, in such a way that most of the time the two dipoles are so oriented as to produce a mutual attraction. This attraction is relatively weak; yet it is strong enough to produce some molecular association at low temperatures.

Association in Gases.—Molecules in the gaseous state are in practically constant motion, frequently colliding with each other. (*See* KINETIC THEORY OF MATTER.) As a rule, when two molecules collide they immediately rebound, remaining close together for only a short time. If, however, the attractive forces between them are strong enough, they stick together for awhile, until the association complex so formed is broken up by a sufficiently energetic collision with another molecule. If the energy of association is considerably greater than the average molecular kinetic energy, most of the molecules are associated at any given instant. Since raising the temperature increases the average kinetic energy of the molecules, it tends to decrease the degree of association, *i.e.*, the average fraction of the molecules which are associated.

As already implied, the degree of association of the molecules in a gas can be computed from measurements of its density at a given pressure and temperature. From a series of such measurements at various pressures, the equilibrium constant at that temperature for the association-dissociation equilibrium can be calculated. From measurements at two or more temperatures the energy of association can be obtained. With this information the degree of association at other temperatures and pressures can be computed.

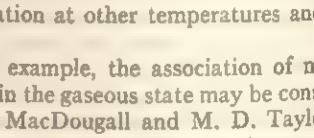
For a specific example, the association of molecules of acetic acid, CH_3CO_2H, in the gaseous state may be considered. Measurements by F. H. MacDougall and M. D. Taylor of the pressure exerted at constant temperature by a given mass of acetic acid vapour in different volumes show that, contrary to the behaviour of a nonassociating gas, the product of the pressure times the volume is not even approximately constant. The data can be quantitatively accounted for by assuming an equilibrium between single and double molecules:

$$2CH_3CO_2H \rightleftarrows (CH_3CO_2H)_2$$

The heat of dissociation is about 15.3 kg.cal. per mole.

The pressure of acetic acid vapour in equilibrium with the liquid at 25° C. is about 15.5 mm. of mercury. Under these conditions 91% of the acetic acid in the vapour is associated. At lower pressures or higher temperatures the association is less.

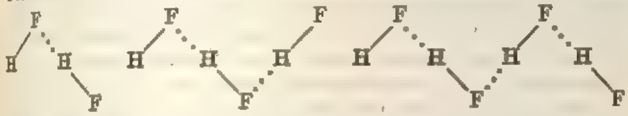
In an electron diffraction study of acetic acid vapour at room temperature and at 143° C. (when the association is about 9%) J. Karle and L. O. Brockway confirmed these conclusions and determined the relative positions of all the atoms except hydrogen in both the simple molecule and the dimer. The structure of the latter can be diagrammatically represented by the following formula:



The complex is held together by means of two hydrogen bridges.

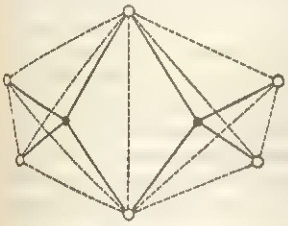
Further confirmation of this structure came from studies of the infrared absorption spectrum by R. C. Herman and R. Hofstadter and others.

Another substance exhibiting association in the gaseous state is hydrogen fluoride, HF. From vapour density measurements by J. W. Mallet, K. Fredenhagen and others, it can be concluded that there is a considerable degree of association even at rather high temperatures. As G. Briegleb showed, the data are best interpreted by assuming an equilibrium between molecules (or aggregates) of various sizes: HF, $(HF)_2$, $(HF)_3$, $(HF)_4$, etc. An electron diffraction study by S. H. Bauer, J. Y. Beach and J. H. Simons confirmed this and showed that the larger molecules have a zigzag structure, with adjacent fluorine atoms held together by hydrogen bonds:



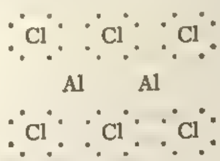
etc.

An example of association which does not involve hydrogen bonds is furnished by aluminum chloride, $AlCl_3$. Vapour density measurements by many workers show that in the gaseous state, below 400° C. (at atmospheric pressure), this substance is almost entirely associated to dimers $(AlCl_3)_2$ or Al_2Cl_6. K. J. Palmer and N. Elliott concluded, from the results of an electron diffraction study, that atoms in the dimer are arranged as indicated in the accompanying figure. The chlorine atoms are tetrahedrally arranged around the aluminum atoms, two chlorines being shared by both aluminums.



ARRANGEMENT OF ALUMINUM ATOMS (DOTS) AND CHLORINE ATOMS (OPEN CIRCLES) IN Al_2Cl_6. THE DIMER OF ALUMINUM CHLORIDE

This association can be explained as a result of the tendency of each aluminum atom, having an excess positive charge, to surround itself by as many negative chlorine atoms as possible, consistent with the requirement that, with each Al–Cl distance near its equilibrium value, the distance between the centres of adjacent chlorine atoms must not be so small as to produce large repulsions between them. Another equally valid point of view is to consider the association as resulting from the tendency of the aluminum atoms to complete tetrahedral four-electron-pair valence shells (octets; *see* VALENCE), as indicated by the following "dot formula":

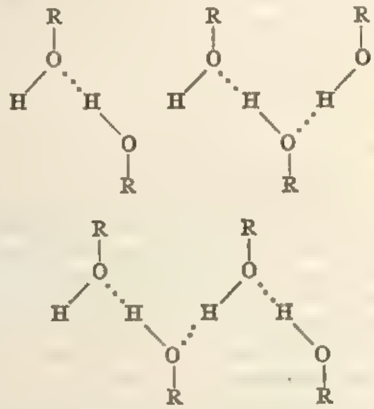


Although one can thus consider the dimer to be held together by chemical bonds, these are relatively weak and the energy required to dissociate the dimer into neutral monomeric molecules is considerably less than that usually associated with a chemical bond; hence, we are justified in considering this an example of association, rather than one of another type of polymerization.

Association in Solution.—Association often occurs between solute molecules dissolved in nonpolar solvents (those consisting of molecules which have no appreciable over-all polarity and which do not contain polar groups), if the mutual attractions between the solute molecules are large relative to the attractions between solute and solvent molecules and relative to the average molecular kinetic energy. Thus, acetic acid molecules, in a solvent such as benzene, are largely associated to dimers, similar in structure to those in the gaseous state. The existence of association is shown, for example, by determinations of the average molecular weight from measurements of the lowering of the freezing point below that for the pure solvent (*see* MOLECULE).

On dilution of a solution in which the solute molecules are largely associated, the degree of association becomes progressively smaller and smaller.

Alcohols (*e.g.*, methanol, CH_3OH) are also associated in dilute solution in nonpolar solvents, but freezing point data indicate the presence of a series of aggregates—ROH, $(ROH)_2$, $(ROH)_3$, . . . —in equilibrium with one another. The situation is closely parallel to that in hydrogen fluoride gas and here also one may confidently assume the aggregates to be held together by hydrogen bonds:



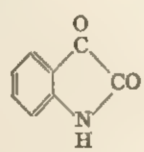
etc.

Association in the Solid State.—Crystal structure analysis by means of X-ray diffraction has led to a knowledge of the distribution in space of the atoms in many solid (crystalline) substances. (*See* CRYSTALLOGRAPHY: *Crystal-Structure Analysis.*)

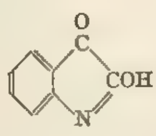
Contrary to previous belief, many of these substances are not composed of molecules. In a diamond crystal, for example, all the atoms (of carbon) are connected, directly or indirectly, by chemical bonds to all the others. If it is proper to speak of molecules at all, each crystal must be considered as comprising a single molecule. This is also true of ordinary salt, sodium chloride, which is composed of positively charged sodium ions and negatively charged chloride ions, in a regular pattern such that each ion is surrounded at the same distance by six of the other kind. There are no diatomic NaCl molecules in the structure.

On the other hand, many solids, especially of organic compounds, can properly be said to be composed of many small molecules. The atoms within each molecule are linked together by ordinary primary valence bonds, the forces between each molecule and its neighbours being much weaker. In some instances X-ray studies have shown the molecules in such solids to be connected by hydrogen bonds in pairs or larger aggregates. It seems justifiable to consider these as examples of molecular association within the solid state.

An interesting example is afforded by isatin (*q.v.*), a coloured organic compound which behaves in some respects as if it had the formula

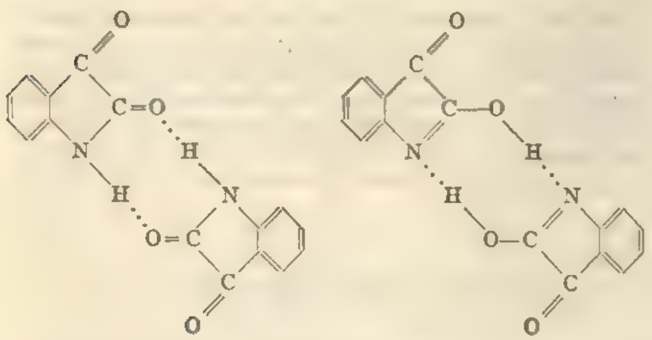


and in other respects as if its formula were



E. G. Cox, T. H. Goodwin and A. J. Wagstaff showed that in the crystal the molecular units are paired in such a way as to indicate

association by means of hydrogen bonds, in accordance with one or the other of the following formulas, or with both of them, in tautomeric equilibrium with each other (*see* TAUTOMERISM):

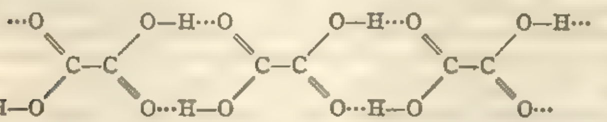


A more precise analysis by G. H. Goldschmidt and F. J. Llewellyn showed that the first of these two structures predominates.

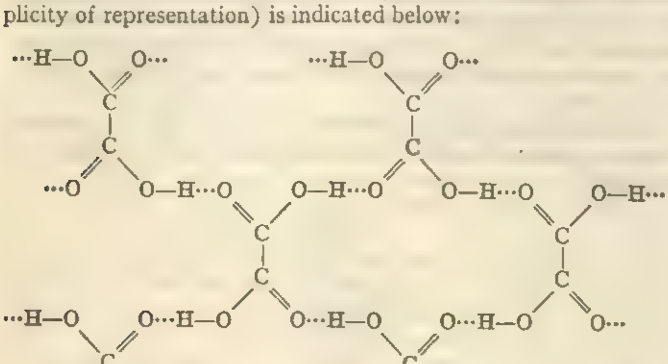
An ice crystal is an aggregate of associated water (H_2O) molecules. W. H. Bragg, interpreting X-ray data obtained by D. M. Dennison, showed that each oxygen atom in the ice structure is surrounded tetrahedrally by four others, equidistant from it within experimental error. The hydrogen atoms are undoubtedly on the oxygen-oxygen centre lines. As indicated by several lines of reasoning, including a thermodynamic argument presented by L. Pauling, each hydrogen is closer to one of its oxygen neighbours than to the other, in such a way that each oxygen has two close hydrogen neighbours and two others slightly more distant. The whole crystal is a giant network of H_2O molecules held together by hydrogen bonds.

Another interesting case is that of oxalic acid, $\begin{matrix} CO_2H \\ | \\ CO_2H \end{matrix}$

Two crystal forms are known. S. B. Hendricks showed, from X-ray diffraction data, that in one form the molecules are associated by means of hydrogen bonds into long chains, extending completely through the crystal:



In the other form the molecules are associated into sheets, each sheet extending completely across the crystal. The approximate distribution of bonds in each sheet (somewhat idealized for simplicity of representation) is indicated below:



Association in Liquids.—In a liquid, association between molecules, by hydrogen bond formation or otherwise, may result in a group of two or more of them remaining attached to each other for a relatively long time. A satisfactory quantitative definition of association in liquids is difficult to make, since it involves decisions as to how close two molecules must be to be considered attached to each other and how long they must be attached to be considered associated.

Even more difficult is the problem of measuring the degree of association in a liquid. Various methods have been proposed, mostly involving departure from the "normal" value of some experimental "constant." One constant is the Eötvös constant appearing in an equation, proposed by Sir W. Ramsay and J. Shields, which relates the surface tension of a liquid to its molecular weight, its density and the difference between the temperature of measurement and the critical temperature of the liquid. As shown by J. H. Hildebrand, greater constancy is exhibited by the entropy of vaporization (the heat of vaporization divided by the absolute temperature) at the temperature at which the vapour has a given volume. In general, the substances for which these constants have values markedly different from those for nonpolar liquids are those which one would expect to be highly associated. Quantitative correlation is difficult, however, and should hardly be expected, since factors other than association are certainly involved.

Many lines of evidence point to the fact that water is one of the most highly associated liquids. Previous to the development and verification of the hydrogen bond theory, liquid water was generally considered to be composed of an equilibrium mixture of various polymers, $(H_2O)_n$, of unknown structure. The modern point of view is that the H_2O molecules throughout the liquid are connected by hydrogen bonds, in much the same manner as in ice (*see* above) but less regularly and with the distribution constantly changing. The higher the temperature, the less perfect is the short-range order, the greater is the average amount of bending of the hydrogen bridges and the more frequently are they broken and reformed.

Alcohol molecules, in the pure liquid state as in solution, would be expected to associate by hydrogen bond formation in a chain-like fashion. This expectation was confirmed by W. H. Zachariasen, interpreting X-ray data from methyl and *n*-nonyl alcohols (methanol and 1-nonanol) obtained by G. W. Stewart and R. M. Morrow. Liquid carboxylic acids would also be expected to associate by hydrogen bond formation, forming both dimers, like those found in the gaseous state, and larger units in which the carboxyl groups are held together in chains.

Many other substances associate to a greater or lesser degree in the liquid state, but, as has been indicated, definite evidence is difficult to obtain In most cases the best that can be done is to reason by analogy with the behaviour of the same or similar substances in the gaseous or crystalline state or in solution. *See also* DISSOCIATION.

ASSOCIATION, MENTAL. Originally the general principle of association was closely linked with problems of recollection. The principle stated that when any past event or experience is recalled, the act of recollection tends to bring again into use other events and experiences that have become related to this event in one or more of certain specified ways. As time went on the application of this general principle was expanded. It was invoked to cover almost everything that can happen in mental life, except original sensations, and "associationism" became a name for theoretical views embracing the whole of psychology.

In this sense, and also as the basis of a complete theory of knowledge, "associationism" is looked upon as a distinctively British doctrine, having a thoroughly empirical outlook and a "common-sense" sanction. It was Aristotle, indeed, who had proposed the three forms of association, by "similarity," by "contrast" and by "contiguity," and in doing so paved the way to much elabo-

rate annotation and controversy. The phrase "association of ideas" was first used by John Locke in *An Essay concerning Human Understanding* (1690). David Hume, nearly 50 years later, maintained in *A Treatise of Human Nature* (1739) that the essential forms of association were by resemblance, by contiguity in time or place and by cause and effect.

Following Hume the chief exponents of associationism were: David Hartley (*Observations on Man*, 1749), James and John Stuart Mill (*e.g.*, *Analysis of the Phenomena of the Human Mind*, 1829), Alexander Bain (*The Senses and the Intellect*, 1855) and Herbert Spencer (*The Principles of Psychology*, 1855). There was much criticism and disagreement about both the number and the proper naming of the forms of association, but in general all the associationists are usually said to hold views which are sensationalist, mechanical and atomistic. Knowledge is held to be acquired originally through one or more of the special senses. By repetitions occurring in the natural course of mental life the original sensory data are interconnected, and can be revived or reinstated as representative images or ideas. All human knowledge is built up from separate, simple and particular experiences, and is analyzable without remainder into these.

During the 1880s there was a strong reaction in England against associationism initiated, from a philosophical and metaphysical standpoint, by F. H. Bradley (*Mind*, 12, pp. 354–381; 1887) and by the analytical psychologists James Ward (in his famous article on "Psychology" for the *Encyclopædia Britannica*, 9th ed., 1875–89) and G. F. Stout (*Analytic Psychology*, 1896). All three basic contentions of the associationists were rejected. Knowledge, it was urged, cannot be founded solely on sensations, for it is impossible that they should be repeated: they happen and perish. It cannot be a product of chance repetition in experience, for there is an inherent element of purpose in all manifestations of mental activity. It cannot be reduced without remainder to simple original elements. None of these critics denied that association was a real mental process, or that it was of great importance within limits, but only that it could be made a basis for everything in psychology, or a firm foundation for the whole structure of knowledge.

The earliest experimental psychologists—W. Wundt and his immediate successors—all assumed that, for experimental purposes at least, sensations must be regarded as ultimate and simple elements, by various combinations of which everything else is built. But at the same time Wundt made it clear that in his view there was no possibility of experimenting, in the proper sense of the word, on the higher mental processes. Hermann Ebbinghaus and others, who developed the nonsense syllable style of experiment upon memory, tacitly accepted a thoroughly associationist standpoint. Their items were regarded as simple, each having, to begin with, no inherent connection with any others, and they acquired their connection by repetition in experience, although in this case the repetitions were controlled and not left to chance.

In *Principles of Psychology* (1890) William James wrote "When two elementary brain processes have been active together or in immediate succession, one of them, on reoccurring, tends to propagate its excitement into the other." This statement, it will be seen, replaced "association of ideas" by an association of central nervous processes set up by overlapping, or immediately successive, stimuli. In 1903 I. P. Pavlov used purely objective methods to study what had been called "association," and he arrived eventually at a complete and elaborate derivation of all behaviour from original and conditioned reflexes. The conditioned reflex theories, and even more literally many of the behaviourist theories which grew up about the same time, were an association psychology of conduct, making essentially the same claims as those of the "association of ideas" doctrines, and open to the same criticism. This is true also of much, perhaps most, of the stimulus-response psychology that became dominant in the United States and that persists in various forms. But as experimenters, who believed firmly in association as an explanatory principle and wanted to make the greatest possible use of it, designed and did more and more experiments, difficulties accumulated. E. L. Thorndike, for example, showed that mere repetition can do little or nothing to establish connections between stimulus and response. He himself considered most important the effect that followed action, and he thought of this effect chiefly in terms of pleasure or unpleasure (*The Fundamentals of Learning*, 1932). Others stressed an alleged direct effect of "knowledge of results" and others, like Clark Hull (*Principles of Behavior*, 1943), produced a complete account of learning mainly in terms of "need reduction," or the strength of the drive linking stimulus and response under various empirical conditions.

All of these—and there were many other varieties of view—demanded not the rejection, but some more or less radical reformulation of associationist principles. During the first ten years of the 20th century, however, came the experiments of the Würzburg school on thinking processes. This school started from a conventional associationist standpoint, but soon claimed to find processes, which were first called *Bewusstseinslagen* (usually translated as "conscious attitudes"), that could neither be derived by association nor accurately described in its terms. There were, it was maintained, vital processes in thinking that did not come from sensations, and could not be expressed in images. Just precisely how these processes were constituted and worked remained far from clear, but the Würzburg group were not calling for a reformulation of associationism, but for its total rejection so far as the higher mental processes were concerned.

About ten years later came the Gestalt psychologists. They would have nothing to do with simple and isolated sensations, and with these discarded all types of associationism. Forms, as well as items, were directly perceived and remained the same forms though the settings changed. The items gained their phenomenal character from the *Gestalten*, or configurations, in which they appeared. The Gestalt psychologists pointed out that if, for example, two stationary spots of light of suitable intensity and duration were exposed at experimentally determinable intervals of time and distance, an observer would see one single moving spot that, it was asserted, could not be analyzed into two discrete experiences corresponding to the two physical lights. The responses made to each stationary spot were changed, and an entirely new kind of experience created. When the details given for observation or treatment constituted a problem, the solution, equally new, often appeared suddenly and by "insight."

For a time Gestalt psychology had a considerable vogue. If its popularity declined, that is perhaps partly because some of its contentions were already familiar, from the discussions of such analytic psychologists as Ward and Stout; partly because as an elaborated psychological system it tended to become enmeshed in a highly speculative kind of physiology; partly because K. Lewin (*Dynamic Theory of Personality*, 1935) prematurely claimed that it justified a psychological dynamics that could be properly expressed in a mathematical form; and partly because psychologists seem to like a fairly frequent change of terminology, even when they do not greatly change their working notions.

The whole associationist treatment of causation, particularly in the form given to it by David Hume, was vigorously attacked by A. Michotte, of the University of Louvain, who based his contentions upon a series of most elegant experiments. Causation, he maintained, is not a generalization arrived at by induction from a large number of instances of regular succession. It is an immediate, compelling and necessary perception given certain simple conditions, as when a form A is seen to move toward another form B and, when they are very close or in actual contact, both move off in the same direction. Then, Michotte asserted, with abundant and varied illustration, B is actually "seen" to be launched into motion by A, and the motion of A is seen to have "caused" that of B.

The completeness or finality of criticisms of association as an all-embracing explanatory principle in psychology is uncertain. Attacks have been made upon associationist theories ever since their elaboration in the late 18th and early 19th centuries. Very few, if any, psychologists or students of the behaviour of animals other than man accord these theories the range and power once claimed for them. This however is mainly because more detailed, and especially experimental, studies have shown that mental associations cannot be formed in the purely mechanical

manner originally demanded, and that the "elements" associated cannot adequately be treated in the atomistic way originally required. Although the conditions of association are not those which the philosophers and psychologists of the pre-experimental period thought sufficient, most psychologists probably agree that association remains a genuinely important and effective principle, active in all instances of "learning through accumulated experience." *See* also CONDITIONING; LEARNING; MEMORY; PSYCHOLOGY.

ASSOCIATION FOOTBALL: *see* FOOTBALL.

ASSOCIATION TESTS are used in psychology to study the organization of mental life, with special reference to the cognitive connections that underlie perception and meaning, memory, language, reasoning and motivation. In the usual "free association" test, the subject is told to give the first word that comes into his mind in response to a word, concept or other stimulus. In "controlled association" a relation may be prescribed between the stimulus and the response (*e.g.*, the subject is asked to give opposites, etc.). Though more complex analyses may be employed for special purposes, the reaction time for each response and the words the subject gives are the basic data provided by the test.

Association tests also are used to investigate personality and its pathology (*e.g.*, the Kent-Rosanoff test). In these the subject's reaction to emotionally charged memories and ideas provoked by certain of the test stimuli may produce atypical or revealing associations or, more often, unusually long or short reaction times. *See* also PSYCHOLOGICAL TESTS AND MEASUREMENTS; PERSONALITY. (H. F. HT.)

ASSOCIATIVE LAWS, in mathematics, are two laws relating to numbers, one with respect to addition and the other with respect to multiplication.

These laws may, respectively, be defined symbolically as follows: $a + (b + c) = (a + b) + c$, and $a(bc) = (ab)c$; that is, the terms or the factors may be associated in any way desired. (*See* also COMMUTATIVE LAWS.) The numbers may be either positive or negative, integral or fractional, rational or irrational and real or imaginary. The laws do not hold throughout the entire range of mathematics, however. For example, the associative law of addition does not hold for certain divergent series.

See also ALGEBRA; ALGEBRAIC GEOMETRY; ARITHMETIC; NUMBER: *Addition and Multiplication;* SERIES.

ASSONANCE, a term defined, in its prosodical sense, as "the correspondence or riming of one word with another in the accented vowel and those which follow, but not in the consonants" (*Oxford English Dictionary*). Much rustic or popular English verse is satisfied with assonance, as in such cases as

> And pray who gave thee that jolly red *nose?*
> Cinnamon, Ginger, Nutmeg and *Cloves,*

where the agreement between the two *o*'s permits the ear to neglect the discord between *s* and *v*. Assonance appears to have preceded rhyme in several of the European languages, and to have led the way toward it. It is particularly observable in the French poetry which was composed before the 12th century, and it reached its highest point in the *Chanson de Roland* (*q.v.*), where the sections are distinguished by the fact that all the lines in a *laisse* or stanza close with the same vowel sound.

When pure rhyme was introduced, about the year 1120, assonance almost immediately retired before it and was employed no more until modern times, when several French poets reintroduced assonance in order to widen the scope of their effects of sound. It held its place longer in Provençal and some other Romance literatures, while in Spanish it continued to retain its absolute authority over rhyme.

It has been observed that in the Romance languages the ear prefers the correspondence of vowels, while in the Teutonic languages the preference is given to consonants. Various German poets of considerable merit, and in particular Johann Tieck and Heinrich Heine, endeavoured, as English rhymers have done, to mix pure rhyme with assonance, but the result of this in almost all cases is that the assonances are drowned in the stress of pure rhymes. Assonance as a conscious art, in fact, is scarcely recognized as legitimate in English literature.

In Celtic poetry, on the other hand, assonance triumphed over pure rhyme, and the Irish poets writing in English who rhymed "Blarney" with "charming" were merely following a national tradition.

See ALLITERATIVE VERSE. (E. G.; X.)

ASSUMPTION, FEAST OF THE, celebrated on Aug. 15 by both eastern and western churches as the principal feast of the Blessed Virgin Mary. It commemorates her death (whence the name Dormition, Falling-Asleep), and especially her taking-up (Assumption) into heaven, body and soul.

This feast originated in the east and came to Rome through Byzantine influence about the middle of the 7th century, under the name of the Falling-Asleep of the Mother of God. Celebrated throughout the Byzantine empire on Aug. 15, but in Egypt on Jan. 18, it had grown out of an earlier "commemoration of the Mother of God" that had been observed during the 6th century and probably even earlier.

This general "commemoration of the Mother of God" had been transformed into a specific "Commemoration of the Falling-Asleep" during the last part of the 6th century under the influence of the *Transitus Mariae*, a 5th-century apocryphal work that nevertheless very likely preserves some half-forgotten traditions.

At Rome the name "Dormition" or "Falling-Asleep" gave way before long to the new title that was to prevail in the west: "the Assumption," which at first meant hardly more than death or passing, but which in time came to imply a real resurrection. When the Roman rite spread through the west during the 9th century the new feast went with it, although there was some opposition to the full implications of the name by which it had become known. By the end of the middle ages the feast was everywhere celebrated as one of the greatest in the year and the doctrine was universally accepted.

In 1950 Pius XII, in *Munificentissimus Deus,* declared that the doctrine was revealed—thereby defining officially what all Roman Catholics had believed for centuries. The Catholic position in the matter is that the Assumption of Mary is implicitly revealed, which means that it is a consequence of her divine Motherhood and perpetual Virginity. (*See* MARY: *Assumed into Heaven.*)

In the Roman rite the feast was given a new mass and office that more clearly state the doctrine and its implications.

See *La Mort et l'assomption de la Sainte Vierge* (1944). (W. J. O.)

ASSUMPTIONIST FATHERS (AUGUSTINIANS OF THE ASSUMPTION), a religious congregation founded in 1845 in Nîmes, France, by Emmanuel d'Alzon and approved by Pius IX in 1864. The Assumptionists' work is chiefly educational, missionary and social. They are organized into seven provinces, in 27 countries, the motherhouse being at Rome. *See* ALZON, EMMANUEL MARIE JOSEPH MAURICE DAUDE D'; ORDERS AND CONGREGATIONS, RELIGIOUS.

ASSUR: *see* ASHUR.

ASSUS (Gr. Assos; in Byzantine times MACHRAMION), an ancient Greek city of the Troad, the site of which is now partly occupied by the port of Behramköy in the Turkish *il* of Canakkale. Lying opposite the north coast of the island of Lesbos and possessing the only good harbour on the north shore of the Adramyttian gulf (Gulf of Edremit), Assus was constructed on the terraces, partly natural and partly artificial, of an isolated cone of trachyte, which rises steeply to a height of more than 700 ft. above the sea.

The city was reputedly founded by Aeolic colonists from Methymna in Lesbos early in the 1st millennium B.C. It retained a degree of independence while the Persians ruled the surrounding district, and one of its tyrants, Hermeas, brought Aristotle to the

city for the three years 347–344 B.C. Taken by Alexander the Great, Assus subsequently passed to Lysimachus, to the kings of Pergamum and then to the Romans. St. Paul visited it on his way to Mitylene.

In modern times the site was quarried, after the Crimean War, for stone for the docks of Istanbul, but much of the old city remains, including the submerged mole of the ancient harbour, parts of the defensive walls, and the ruins of a fine Doric temple of Athena. (WM. C. B.)

ASSYRIA (now part of northern Iraq) is the Greek form of a geographical name "land of (the god) Ashur," used in the cuneiform texts to denote the homeland of the Assyrian people, whose political importance in ancient western Asia lasted, with many vicissitudes, from about 2000 to 612 B.C. Ashur was thus the name of a god, a city and a country. The city of Ashur (*q.v.*) itself lay on the Tigris river about 40 mi. S. of its confluence with the Great Zab river, but the heart of Assyria was in the angle formed by these two streams, where lay the cities of Kalakh (Calah, modern Nimrud), Dur Sharrukin (modern Khorsabad) and Ninua (Nineveh, opposite Mosul), the capital of Assyria in the last years of its empire (8th–7th centuries B.C.). The political boundaries of Assyria to the north and east were naturally defined by mountains rising from the steppe, and to the west they varied greatly through the centuries according to the strength or weakness of the government, but to the south over against the still longer-enduring kingdom of Babylonia, a sister-state but often a bitter enemy, the boundary was usually about latitude 34° N. where the tributary Nahr al Uzaym joins the Tigris river. For a general account *see* BABYLONIA AND ASSYRIA. (C. J. G.)

ASSYRIAN LANGUAGE: *see* AKKADIAN LANGUAGE.

ASTARTE, the great goddess of the Semitic pantheon, and the chief deity of Sidon. The inscription of the Phoenician king of Sidon, Eshmunazar, records the building or restoration of a temple to Eshmun, the Baal of Sidon, and to "Astarte of the name of Baal." Tabnit, son and successor of Eshmunazar, was priest of Astarte. In Jerusalem, Solomon built for her a high place which king Josiah "defiled" (I Kings xi, 5; II Kings xxiii, 13). Figurines, plaques and reliefs found at many places in Palestine show that her cult as goddess of fertility and reproduction was widespread. Some of her images show foreign influence; those with a lotus flower in the hands and two long ringlets adorning the head point toward Egypt.

Astarte was worshiped in Cyprus, in Sicily, in Sardinia and at Carthage. She became identified with the Egyptian deities Isis and Hathor. By the Greco-Roman world she was assimilated to Aphrodite and Artemis, Diana and Juno. Her identification with Aphrodite/Venus suggests that she was equated with the planet Venus by the Syrians just as Ishtar (*q.v.*) was by the Babylonians. Under Egyptian influence she became the moon. This she cannot have been originally because to the Semites the moon was a male deity; the Phoenicians spread the cult of the moon as a goddess.

Because the Akkadian form of her name, Ishtar, and the Sabaean form, Athtar, both lack the Semitic feminine termination, it is possible that, like Athtar, Ishtar was originally male. Elsewhere the form of Astarte's name and the contexts in which it occurs define her as female. It is rendered Astarte in the Septuagint (Greek) version of the Bible and Ashtoreth (plural Ashtaroth) in the Hebrew, being there vocalized as *bosheth,* "shame," to indicate Hebrew contempt for her cult. The Moabites, neighbours of the Israelites, worshiped Ashtar-Chemosh. This compound name may indicate that Astarte was the spouse of the Moabite Baal; the Bible makes her the spouse of the Baal of Carmel—if, as is likely, the English rendering "prophets of the groves (Asherah)" stands for an original "prophets of Ashtoreth" (I Kings xviii, 19). Another compound of mixed sex is the divine Atargatis (*q.v.*), from Attar (Ashtart) and Atte (Anat). Atargatis is goddess of Ascalon in Palestine and identical in mythology with the maiden Derketo who, according to the Greek historian Diodorus Siculus, threw herself into a lake full of sacred fish near Ascalon, is associated with pools and fish and is represented with a body tailing off in the form of a fish (unlike the Astarte of Hierapolis near Aleppo, to whom also fish were sacred). At Ascalon the Philistines deposited the armour of Saul in the temple of Ashtoreth Astarte (I Sam. xxxi, 10).

See E. (Paul) Dhorme, *Les Religions de Babylonie et d'Assyrie* (1949). (T. FH.)

ASTATINE (chemical symbol At, atomic number 85), a synthetically produced chemical element, is the only member of the halogen family having no stable isotopes. Its name is from the Greek *astatos,* meaning unstable.

It is to be expected that all isotopes of astatine are radioactive. Therefore the only possibility of finding them in nature would be by virtue of their having very long half-lives, of the order of 10^9 years, or by their being in radioactive equilibrium with long-lived substances. No isotope of astatine has such a long life, but At^{218} and At^{219} have been found as rare branch products in the natural radioactive families.

Astatine was first prepared in 1940 at the University of California by Dale R. Corson, K. R. Mackenzie, and Emilio Segrè. They bombarded bismuth with alpha particles, obtaining a nuclear reaction that can be written $Bi^{209} + He^4 = At^{211} + 2n$. The isotope thus produced has a half-life of 7.5 hr. and shows a dual decay such that about 60% of the atoms emit alpha particles of 5.94 Mev (million electron volts) energy and transform into Bi^{207}, and the remaining 40% transform by orbital electron capture into Po^{211} (AcC′), which in turn emits alpha particles of 7.43 Mev energy to become Pb^{207} (AcPb). (For explanations of these radiochemical findings *see* RADIOACTIVITY.)

The longest-lived isotope of astatine has mass 210 and a half-life of 8.3 hr. It is best obtained by an (α, 3n) reaction on bismuth and it decays by orbital electron capture. By the 1960s about 19 isotopes ranging from mass number 201 to 219 had been identified. All have lives shorter than At^{210}.

From its position in the periodic table (following polonium and preceding radon) astatine would be expected to behave as a halogen, although the metallic properties already detectable in iodine should be more marked. Its electronic structure is a gold core plus $6s^2$, $6p^5$. Another 6p electron is needed to complete the radon core. This configuration has been verified by molecular beam experiments.

Using At^{210} and At^{211}, and employing the ordinary methods of radiochemistry, it has been possible to establish some of the chemical properties of the element. In general it resembles iodine (and, like iodine, it concentrates in the thyroid gland); however, in the normal course of qualitative analysis it appears in the group of metals having sulfides insoluble in acid solution. Its reaction to silver ion is markedly different from those of the other halogens. Under suitable conditions it is soluble in organic solvents. The ionic species At^-, At^0, and AtO_3^- and such organic compounds as $AtCH_3$ have been recognized either chemically or with the help of the mass spectrograph, or both.

Sci.,* 9:203–220 (1959); A. H. W. Atens, Jr., "The Chemistry of Astatine," *Advs. in Inorg. Chem. Radiochem.,* 6:207–223 (1964). (Eo. S.)

ASTER, a large genus of plants of the family Compositae (*q.v.*), so named from the radiate or starlike appearance of the flowers, and known as asters or starworts (Gr. *aster,* "a star"). Numerous species are described (estimates vary from 250 to 600), found chiefly in North America but scattered sparsely in Asia, Europe and South America. They are usually perennial, leafy-stemmed herbs, sometimes somewhat woody at the base, and bearing in late summer and autumn a profusion of flowering heads, mostly in clusters, but sometimes solitary. In each head numerous showy blue, red, purple or white rays surround a central disk of minute yellow tubular flowers. Many are strikingly handsome and cultivated as ornamental fall-flowering plants. The Michaelmas daisy is the finest of the cultivated sorts, its scores of varieties having been developed by hybridizing. Only one species, *A. tripolium,* is native to Great Britain.

In North America there are more than 175 species, most numerous in the northeastern United States and adjacent Canada. They are generously represented in the Rocky mountain region, about 40 species being found in Utah and Nevada and about 20

ALBERT W. KERR

MICHAELMAS DAISIES (ASTER AMELLUS), KING GEORGE V VARIETY

occurring in California. In the region east of Manitoba and Kansas and north of Tennessee, the asters, together with the goldenrods, dominate the floral landscape in autumn, filling fields, woodlands and roadsides with masses of brilliant colour. Among the many conspicuous kinds the New England aster (*A. novae-angliae*), found abundantly from Massachusetts to Alberta and south to Alabama and New Mexico, is the best known. It grows three feet to five feet high with handsome purple heads one and one-half inches to two inches across. Other noteworthy species are the New York aster (*A. novi-belgii*) and the smooth blue aster (*A. laevis*), both of which, like the foregoing, are widely cultivated. In California the common aster is *A. chilensis;* other noteworthy species are the somewhat woody desert aster (*A. tortifolius*) and the reedlike spiny aster (*A. spinosus*), which grows nine feet high in the southwestern deserts and is popularly called Mexican devilweed. The China aster (*Callistephus chinensis*) is also a member of the family Compositae. It is a hardy annual, a native of eastern Asia, and has yielded a great variety of forms. They are commonly known as garden asters in spite of not belonging to the genus *Aster.*

All the perennial species, especially the best of them, the Michaelmas daisy, need a reasonably rich soil, full sunlight and not too much summer heat. It is the latter that has made their culture difficult in many parts of the U.S., but most successful in England where dozens of varieties are commonly grown.

The native American woodland species are easily transplanted from the wild, but are apt to be rather weedy garden plants. All can easily be divided in spring or autumn and most Michaelmas daisies need such division and replanting every second or third year.

(N. Tr.)

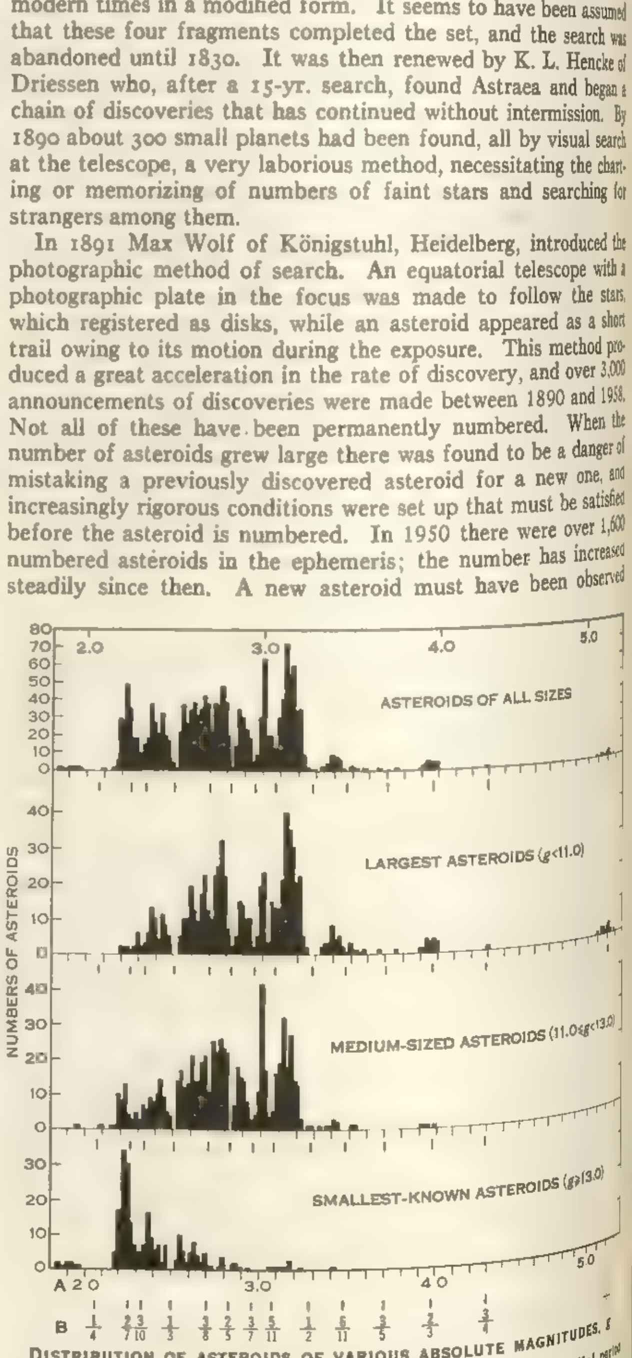
ASTEROIDS. The asteroids, or minor planets, are a vast host of very small planets that revolve around the sun in orbits that nearly all lie between those of Mars and Jupiter, though a few of them transgress these limits. The existence of a planet between Mars and Jupiter was suspected before any were found on the basis of an empirical law of planetary distances first put forward by J. D. Titius in 1766 though it attracted more notice when Johann E. Bode restated it in 1772. The law assigned the following numbers as representing the distances very closely: Mercury 4; Venus 7; Earth 10; Mars 16; (blank) 28; Jupiter 52; Saturn 100; (next planet) 196. It will be seen that, except in the first case, each interval is double the preceding one.

When in 1781 Sir W. Herschel discovered Uranus, which fitted exactly with the next term in the series after Saturn, conviction was strengthened of the existence of a planet in the gap, and a society of 24 astronomers, with Baron von Zach at its head, was formed to devote itself to the search. Giuseppe Piazzi, director of the Palermo observatory, was not a member of this society, but on Jan. 1, 1801, while examining a region in Taurus, he observed a small star which he had not seen there before; he soon found that it was moving, and followed it until Feb. 11. In the interval it ceased retrograde motion, and began to advance. In the following autumn difficulty was experienced in finding the body again; this served as an incentive to the mathematician Carl Friedrich Gauss to improve the existing methods of computing orbits from a few observed positions. As a result of Gauss's calculations Heinrich W. M. Olbers of Bremen recovered Piazzi's planet just a year after its discovery. (The three astronomers associated with the finding of the first asteroid have been commemorated by naming the planets numbered 1,000, 1,001 and 1,002 Piazzia, Gaussia and Olbersia.)

The new planet was named Ceres; its distance agreed exactly with the value predicted by the Titius-Bode law, but it was very small (modern measurements give a diameter of 470 mi., about one-fifth of the moon's) and its orbit was inclined to the ecliptic at the large angle of 10° 37′. Perhaps these circumstances led Olbers to suspect that it was one of a group of small planets for he continued to sweep the sky after he had recovered it, and three months later he found Pallas, whose distance from the sun proved to be almost the same as that of Ceres. Its orbit was inclined at the very large angle of 34° 43′, and the eccentricity was also large. The third and fourth members, Juno and Vesta, were added to the family within six years by C. L. Harding and Olbers respectively. Vesta is the brightest of the whole family, sometimes attaining visibility to the naked eye, but its diameter is only half that of Ceres.

It was natural that the discovery of these four little planets, revolving in closely adjacent orbits, should suggest the idea that a larger orb had been rent asunder by an explosion. This idea held the field for many years, and indeed was revived in modern times in a modified form. It seems to have been assumed that these four fragments completed the set, and the search was abandoned until 1830. It was then renewed by K. L. Hencke of Driessen who, after a 15-yr. search, found Astraea and began a chain of discoveries that has continued without intermission. By 1890 about 300 small planets had been found, all by visual search at the telescope, a very laborious method, necessitating the charting or memorizing of numbers of faint stars and searching for strangers among them.

In 1891 Max Wolf of Königstuhl, Heidelberg, introduced the photographic method of search. An equatorial telescope with a photographic plate in the focus was made to follow the stars, which registered as disks, while an asteroid appeared as a short trail owing to its motion during the exposure. This method produced a great acceleration in the rate of discovery, and over 3,000 announcements of discoveries were made between 1890 and 1958. Not all of these have been permanently numbered. When the number of asteroids grew large there was found to be a danger of mistaking a previously discovered asteroid for a new one, and increasingly rigorous conditions were set up that must be satisfied before the asteroid is numbered. In 1950 there were over 1,600 numbered asteroids in the ephemeris; the number has increased steadily since then. A new asteroid must have been observed



DISTRIBUTION OF ASTEROIDS OF VARIOUS ABSOLUTE MAGNITUDES, g

(A) Semimajor axis, a, in astronomical units; (B) fractions of the orbital period of Jupiter

during three oppositions to qualify for numbering. Even so, misidentifications in the published records have occurred and a systematic campaign during the decade 1948–58 was necessary to clear up most of the ambiguities. (A. C. DE C.; F. L. WE.; G. P. K.)

STATISTICS OF THE ASTEROID RING

The elliptical orbit of an asteroid is characterized by the semimajor axis a; the eccentricity e; the inclination on the ecliptic i; and quantities of lesser interest (*see* also PLANETS: *Orbits and Phases of Planets*). The asteroid itself has at opposition an apparent magnitude from which may be computed the absolute magnitude g (reduced to unit distance from the earth and from the sun); a true diameter d; an albedo, or reflectivity; a colour; and certain photometric and polarimetric properties found when observations are made away from opposition at different phase angles. Ceres has the largest diameter, just under 500 mi. The smallest objects observed are less than one mile in diameter. The albedos may be derived for only the 12 or so asteroids showing measurable disks. The value is roughly seven per cent, about the same as for the Moon and Mercury; Vesta is an exception, being nearly twice as bright. The colours of the asteroids vary somewhat, the average being a slightly yellowish gray, similar to the Moon and Mercury. None has been found to be as ochre as Mars. The colour does not appear to depend on the size of the asteroid. The photometric and polarimetric properties also resemble those of the Moon but some interesting differences have been found.

The distribution of asteroids with respect to a is shown in the chart, for three groups: largest asteroids ($g < 11.0$ or $d > 20$ mi.), a middle group ($11.0 < g < 13.0$ or $8 < d < 20$ mi.) and the smallest known objects ($g > 13.0$ or $d < 8$ mi.). Data on the smallest objects are very incomplete at the greater distances owing to their faintness. Only the bright objects may be regarded as complete over the entire range of a. It is noted that all three distributions show gaps. They are the Kirkwood gaps, named after their discoverer, D. Kirkwood. At their positions the periods of revolution are simple fractions of the orbital period of Jupiter. Particularly prominent are the gaps at the periods $\frac{1}{4}$, $\frac{1}{3}$, $\frac{2}{5}$, $\frac{3}{7}$, $\frac{1}{2}$ and $\frac{3}{5}$ of Jupiter. Where the fraction is $\frac{2}{3}$ and $\frac{1}{1}$ there are, by contrast, accumulations. The $\frac{1}{1}$ accumulation is the so-called Trojan group (*see* TROJAN PLANETS), of which 15 members are definitely known and several others are suspected. They occur near the points that define equilateral triangles with the Sun and Jupiter, situated in the plane of the Jupiter orbit. Motion around these points is stable if the amplitude of the oscillation does not exceed a certain value.

The width of the Kirkwood gaps is related to the mass of Jupiter. E. K. Rabe in this manner derived the mass responsible for the gaps and found it to be about 20 times the mass of the present planet. This value for the mass of proto-Jupiter confirmed earlier estimates by G. P. Kuiper based on his theory of the origin of the solar system. The orbits of the Trojans also contain important information on this subject. Kuiper assumed the Trojans to be former satellites of Jupiter, released because of the planet's mass decrease and forced into orbits around the triangular points. Rabe's analysis of this hypothesis also led to a mass of proto-Jupiter of about 20 times the present planet.

Additional information is obtained by a consideration of the orbital eccentricities and inclinations. These elements undergo fluctuations due to perturbations of the major planets, especially Jupiter. Average, or proper, values of e and i that are free of these fluctuations may be computed. The three-dimensional distribution of proper elements, a, e and i, then shows clusterings of asteroids on a general background which are called Hirayama families. K. Hirayama found ten such groups, comprising about $\frac{1}{6}$ of all known asteroids; D. Brouwer extended the number to 29 groups comprising 29% of the known asteroids. Some families, like the Coronis family, are tightly packed in the plot while others are loose and some may not be genuine groups. The origin and nature of these families has been debated. Brouwer regards them as compatible with an origin by collisional break-up, the fragments of one break-up resulting in one family. Rabe favours an earlier explanation by E. W. Brown who regarded them as "groups of comparatively stable orbits developed by the attractive forces, and might have arisen from a great variety of configurations." (Eugene Rabe, *Zeitschrift für Astrophysik*, vol. 40, p. 107, Springer-Verlag, 1956.) The uncertainty arises from the fact that the gravitational theories are not accurate beyond intervals of some tens of millions of years or about one per cent of the age of the solar system.

The distribution by absolute magnitudes g (or by diameters) shows interesting features. The different distance zones of the asteroid ring have notable population differences, with the zone from 3.0 to 3.5 astronomical units showing the most rapid increase toward the smaller bodies. The apparent discrepancy between this statement and the diagram is caused by the fact that the chart represents all that is *known* and not all that is present. This increase is so rapid, in fact, that the total mass per magnitude interval for the fainter asteroids continues to increase so that the total mass of the asteroid ring cannot be computed. It further means that the fragmentation by collisional break-up will be most rapid in the 3.0–3.5 unit zone. This zone must therefore be the region where the meteorites are formed. The brightness distributions of the three main parts of the asteroid ring all show two groups to be present: those larger than about 20 mi. in diameter; those smaller, with a discontinuity in the distribution near 20 mi. This feature may be due to two modes of asteroid formation: the larger having formed by condensation and accretion; the smaller largely by fragmentation in collisions.

The brightness of nearly all asteroids is found by continuous observation to vary by small amounts. The variations are periodic, with each cycle showing two light maxima and two minima. This state of affairs can be explained if the asteroids are nonspherical bodies in rotation; then during one period they will show twice a maximum projected area and twice a minimum area, as is verified by rotating an object of arbitrary shape. Only when the object is seen pole-on will there be no light variation. Since an asteroid may be observed in many different parts of the sky, owing to the orbital motions of both Earth and asteroid, many aspects can be studied and combined to give data on both the shape of the body and the position of the pole of rotation. The results are that the periods may be anywhere from 3 to over 20 hours, with 6–8 hours being rather typical; and that the poles of rotation approximate a random distribution in space. These results are not surprising in view of the many collisions that asteroids must have experienced; but one aspect was at first unexpected: that the collisions did not cause the axes of rotation to differ from the figure axes, which would have caused the asteroids to wobble in their rotational motions. Such a wobbling motion (latitude variation) has not been found; such motion would have led to nonperiodic light variations, contrary to observation. This result has been explained as due to damping of the latitude variation; K. Prendergast has shown that this damping occurs well within 1,000,000 years, so that only asteroids having suffered extremely recent collisions would still be expected to show the effects.

The composition and age of the asteroids may be ascertained through the study of meteorites, which, if many authorities are correct, are asteroid fragments that have fallen on the earth. Meteorites are fragments of bodies that have in large part melted; the time elapsed since the subsequent solidification is about 4,500,000,000 years. The parent bodies appear to have been asteroidal in size: they were large enough to permit the accumulation of radioactive heat until melting set in and to later cause very slow cooling during crystallization; but they were small enough to prevent vigorous gravitational separation of the iron phase and the silicate phase of the melt as is seen from silicate inclusions in the iron phase and vice versa. It is true that very small diamonds have been found in some meteorites and, since laboratory production of diamonds requires high pressures, it has been assumed that the parent bodies were nearly the size of Mars. However, there is no evidence of such large mass concentrations in the asteroid ring and the presence of diamonds is not definite proof of the action of high pressures, since asteroidal pressures operating over long periods of time may be sufficient for their production. The study of asteroids through meteorite

fragments is one of the most fascinating and productive fields in astrochemistry. The orbital characteristics of the meteorites also present challenging problems, such as the application of gravitational perturbation theory involving very long intervals of time.

ASTHENIA, lack or loss of strength, is a condition in which the body lacks or has lost strength either as a whole or in any of its parts. General asthenia occurs in many chronic wasting diseases such as anemia and cancer. It is probably most marked in diseases of the adrenal gland, where it dominates the whole picture. Asthenia may be limited to certain organs or systems of organs. Thus there is asthenopia (*q.v.*), which is characterized by ready fatigability of vision and myasthenia gravis, in which there is progressive increase in the fatigability of the muscular system until death results from inability of the heart muscle to continue its work. In neurasthenia and psychasthenia there is a strong subjective sense of fatigue in the absence of real weakness.

ASTHENOPIA is a condition in which the eyes are weak and tire easily. It may be brought on by disorders in any of the various complicated functions involved in the visual act. Thus imbalance between the muscles that keep the eyes parallel leads to fatigue in the constant effort to prevent double vision. Errors in refraction lead to fatigue of the muscles of accommodation in the continued compensation demanded of them. Clouding of the lens or of the media that transmit the light may bring it about, and finally disorders of the retina, where the impressions are received, will lead to fatigue.

The symptoms are pain in the eyeball, frontal headache, blurring of vision and smarting and watering of the eye. These are usually worse toward evening and are aggravated by close work such as reading and sewing.

ASTHMA, a lung condition that owes its name to its predominant clinical symptom, shortness of breath. The word "asthma" means panting. If asthma is caused by obstructed airways, it is said to be bronchial; if red blood cells fail to carry oxygen away from the lungs, it is cardiac.

Asthma has a high morbidity but a surprisingly low mortality, and asthmatics can lead useful lives. The long-term problem is prevention, not treatment. Since multiple factors—heredity, environment, hormones, stress—determine its course, successful care requires adequate control not only of the respiratory tract but more or less of the patient as a person.

Normally, air is carried into the lungs through airways—bronchi and, as they become smaller, bronchioli—to blind terminal sacs, the alveoli. The alveolar walls consist of a thin membrane interwoven with elastic fibres. On the outer wall of each sac, red blood cells move slowly through tiny blood vessels and, as they move, exchange carbon dioxide for oxygen through the membrane. If blood stagnates, this exchange is halted and cardiac asthma results.

Bronchial asthma is caused by any obstruction of the airways that prevents oxygen from reaching the alveoli. Circular muscles control the width of the bronchi and, thus, the flow of air; simultaneously, blood vessels, like radiators, adjust the temperature, and mucous glands provide humidification. The proper functioning of these air-conditioning structures is maintained by autonomic nerves that can, when the need arises, excite or inhibit them. Allergic patients, during allergic episodes, produce histamine, a substance that overrules this physiological balance and incites muscles, blood vessels and mucous gland to work, regardless of need, at maximal capacity.

Allergy as a Cause.—The chain of events culminating in an allergic asthmatic attack begins with the peculiar, inherited ability of the allergic individual to become sensitive to allergens, particles in the air that are innocuous for nonallergic people. Common allergens include pollens of certain trees, grasses and other plants, especially ragweed; spores of molds; small scales (dander) from the hair or feathers of animals; house dust; and certain chemicals; *e.g.*, components of hair dyes or insecticides. Food not infrequently causes bronchial asthma in children, rarely in adults.

Once sensitivity exists, re-exposure to the allergen releases histamine, which, in a three-fold action: (1) increases vascular permeability so that the tissue becomes waterlogged; (2) induces profuse secretion of mucus; and (3) constricts circular muscles. Many people are allergic, but most of them have nasal rather than bronchial symptoms. In the lungs, histamine produces the three cardinal features of bronchial asthma: (1) shortness of breath and other signs of oxygen want, such as laboured breathing, blueness of lips or a rapidly beating heart; (2) wheezing—a unique sound made by air passing through narrowed, mucus-filled bronchi; and (3) coughing, a reflex that produces expectoration.

Nonallergic Bronchial Asthma.—Bronchial asthma is not always allergic. In some patients, the autonomic nerves induce constriction of muscles or secretion of mucus when neither is required. Asthma from this cause usually begins after middle age and has been called intrinsic to distinguish it from extrinsic allergic asthma, which generally begins before adolescence. Infection complicates bronchial asthma; there is some evidence that infection might actually cause it, but the exact mechanism by which infection affects asthmatics is not known.

Effects on Lungs.—Oxygen deficiency compels the asthmatic to force air into his lungs. As the pressure increases, the stretched alveoli become choked with air. The pressure may tear the tender membrane and produce scar tissue, which is tough but useless. This stretching and scarring produces the inflated, ineffective lung of pulmonary emphysema. Yet, some patients may have bronchial asthma throughout their lives without scarring, while others develop early irreversible changes.

Treatment.—Treatment of cardiac asthma demands mobilization of the stagnating blood through treatment of the heart rather than the lung.

Specific treatment of bronchial asthma consists of (1) prevention of initial exposure, *i.e.*, sensitization, of allergic individuals; (2) prevention of re-exposure of those already sensitized; and (3) immunization procedures that may decrease an existing sensitivity.

Symptomatic treatment can reverse the effect of histamine. This treatment consists of administering epinephrine (adrenaline) or drugs similar to epinephrine, the chemical produced in the body that widens bronchi and inhibits mucous glands. Epinephrine originates in the marrow of the adrenals, small glands that overlie the kidneys. The outer layer of the adrenals produces a different hormone, hydrocortisone, which, through a different mechanism, also controls bronchial asthma. Hydrocortisone eliminates waterlogging but does not influence the disease itself, which recurs after withdrawal of the hormone. Administration of hydrocortisone is not without risk, although the newer synthetic derivatives appear to be safer.

In some patients it may be necessary to administer oxygen in higher-than-air concentration for limited periods, until tenacious mucus liquefies. Breathing exercises are often helpful. Weather influences bronchial asthma, but its importance tends to be exaggerated; only a few patients will benefit from a change in climate. Emotional stress alone is unlikely to give rise to bronchial asthma, but it may make the patient asthma-prone. Moreover, the patient who has recovered from severe attacks may be apprehensive; he needs reassurance and, particularly, a clear understanding of measures that provide immediate relief. Bronchial asthma cannot be cured, but it certainly can be controlled.

See HISTAMINE; RESPIRATION: *Ventilation of the Lungs in Man;* RESPIRATORY SYSTEM, ANATOMY OF: *Lungs.* (M. SA.)

ASTI, a city of northwest Italy, capital of the Asti province in the region of Piedmont, lies on the Tanaro river 35 mi. by road east-southeast of Turin. Pop. of commune (1961) 62,172. The 14th-century cathedral is in Gothic style, the collegiate church of S. Secondo (15th century) has a Romanesque campanile, the Trojan tower (13th century) is the highest medieval tower in Piedmont, and other interesting buildings include the eight-sided

baptistery of S. Pietro (10th century), and the churches of S. Giovanni and S. Atanasio with crypts of the 7th and 8th centuries. Asti is noted for its fine wines, of which the best-known are Asti spumante, Barbera, Grignolino and Freisa; and for its fruits. The town was called Hasta Pompeia by the Romans. It is the birthplace of the Italian tragedian Vittorio Alfieri (*q.v.*).

ASTIGMATISM, a form of aberration in optical systems, as a result of which rays proceeding from a point source form an area instead of a point and thus cause blurred vision. In the eye it is caused by uneven and unequal curvatures on the various refractive surfaces (*i.e.*, the cornea and lens) that diffuse the rays and interfere with a sharp focus at a point on the retina.

See OPTICS; VISION; *see* also Index references under "Astigmatism" in the Index volume. (F. L. A.)

ASTIN TAGH (ALTYN TAG), the northernmost range of the Kunlun mountains (*q.v.*), in Sinkiang, China. It extends from the Tokuzdavan pass (86° E.) in a northeasterly and easterly direction to the borders of Kansu, where the Tangyn pass (94° E.) separates it from the Humboldt range. In the west it rises steeply above the Takla Makan desert of the Tarim basin; at this end of the range there are extensive glaciers. Maximum height 17,716 ft. Lake Lobnor lies north of the centre of the range, while the eastern half of the range limits the Tsaidam depression, forming its northeastern boundary. (R. E. F. S.)

ASTLEY, JACOB ASTLEY, BARON (1579–1652), English soldier, who was a royalist commander in the English Civil War, came of a Norfolk family. He served under Maurice and Henry of Orange in the Netherlands in 1598 and afterward fought under Frederick V of the Palatinate and under Gustavus Adolphus in the Thirty Years' War. Returning to England with a well-deserved military reputation, he was employed by Charles I in various capacities. At the outbreak of the Civil War (1642) he was made major-general of the foot. His battle prayer at Edgehill (Oct. 1642) has become famous: "O Lord, Thou knowest how busy I must be this day. If I forget Thee, do not Thou forget me. March on, boys!" He led the infantry of the royal army in the first battle of Newbury (Sept. 1643) and gallantly defended Shaw house in the second (Oct. 1644). In Nov. 1644 he was created baron. At Naseby (June 1645) he commanded the main body of the royalist foot. Later in 1645 he was commander in south Wales, afterward serving in the west. With 1,500 men he fought stubbornly but vainly for the king in the last battle of the first phase of the war, at Stow-on-the-Wold (March 1646). His remark to his captors has become as famous as his words at Edgehill: "You have now done your work and may go and play, unless you will fall out amongst yourselves." Because he had given his parole at Stow-on-the-Wold, his scrupulous honour forbade him to take any part in the second phase of the Civil War. He died at Maidstone, Kent, in Feb. 1652. (S. R. BT.)

ASTON, FRANCIS WILLIAM (1877–1945), English scientist, was the recipient of the Nobel prize in chemistry (1922) for his development of the mass spectrograph, discovery of many isotopes, and formulation of the whole number rule. He was born in Harborne, Birmingham, on Sept. 1, 1877, and educated at Malvern college and the universities of Birmingham and Cambridge. His early training and employment was as a chemist, but the rebirth of physics following the discovery of X-rays and radioactivity (1896) was too exciting to miss. He returned to the University of Birmingham in 1903 to study gaseous discharges, the method then used for the production of X-rays. In 1909 he accepted an assistantship at Cambridge university with J. J. Thomson, who was investigating the positively charged rays emanating from gaseous discharges. It was during the period of Aston's assistantship that Thomson obtained, from experiments with neon, the first evidence for isotopes (*q.v.*) among the stable elements. Aston set out to verify or disprove Thomson's evidence. Returning to Cambridge after World War I Aston constructed a new type of positive ray apparatus which, because of its similarity to optical spectrographs, he named a mass spectrograph. (*See* MASS SPECTROSCOPY.)

The mass spectrograph was an immediate success. Not only did it show that neon is indeed a mixture of isotopes, but that many elements are mixtures of isotopes. Aston's success is illustrated by the fact that of 287 naturally occurring isotopes, he discovered 212. A second success, which illustrates the importance of his background in chemistry, was the calculation of chemical atomic weights from the physically determined isotopic masses and abundances. A third success was the formulation of the whole number rule; *i.e.*, with the mass of the oxygen isotope defined as exactly 16, all other isotopes have masses that are very nearly whole numbers (*e.g.*, U^{235}). Aston continued to measure, with ever greater precision, the exact masses of the isotopes. These masses are fundamental to nuclear theory. In the mid-20th century there were few fields of scientific research that did not depend on his work.

Aston's achievements were recognized by his election as a fellow of Trinity college (1920) and as a fellow of the Royal society (1921); and his receipt of the Nobel prize and the Hughes medal (1922), the John Scott medal and the Paterno medal (1923), the Royal medal (1938) and the Duddell medal (1945). He was an honorary member of the Russian academy of sciences and the Accademia dei Lincei. He died in Cambridge, Nov. 20, 1945. (M. G. I.)

ASTON, HUGH (*c.* 1490–*c.* 1550), English composer of church music. Various spellings of his surname are found, and his identity has been long obscured by the fact that there was at the same period a prominent ecclesiastic of the same name, a canon of York and of St. Stephen's, Westminster. It has been established that the composer, born *c.* 1490, supplicated for the degree of B. Mus. at Oxford in 1510 and was master of the choristers at St. Mary's college, Leicester, from some time before 1525 until its dissolution in 1548. He was already well enough known in 1525 for the bishop of Lincoln to recommend him to Cardinal Wolsey for the latter's lavish new foundation at Oxford (Cardinal college, later Christ Church); he refused the offer, however, and the post went to John Taverner. Aston died sometime after 1549.

The style of Aston's music (most of it reprinted in *Tudor Church Music*, vol. X, 1929) in its rich, largely nonimitative counterpoint is very close to that of Taverner, though Aston lacks Taverner's melodic suppleness and control of large-scale designs. (J. J. N.)

ASTOR. The name of an Anglo-American family founded by JOHN JACOB ASTOR (1763–1848), who was born near Heidelberg, Ger., on July 17, 1763, emigrated to America in 1783 and entered the fur business in 1786. He devoted many years to organizing the fur trade from the Great Lakes to the Pacific ocean and from there to China and Japan, exchanging fur for tea at great profits. His American Fur company was the first American business monopoly. The greater part of the family fortune, however, was obtained by acquiring and developing real estate in New York city. Astor was a leader in chartering the 2nd Bank of the United States. He died on March 29, 1848, his wealth then being estimated at over $25,000,000. His principal benefaction was $400,000 for the foundation and endowment of a public library.

His son WILLIAM BACKHOUSE ASTOR (1792–1875), who was born in New York city on Sept. 19, 1792, added greatly to the family fortune, erecting about 700 stores and dwellings in New York city. He died on Nov. 24, 1875, leaving the bulk of his estate to his two oldest sons. JOHN JACOB ASTOR 3rd (1822–1890) was born in New York city on June 10, 1822. Inheritances from his father and grandfather made him the largest private owner of real estate in New York city. In the Civil War he served for a year on the staff of Gen. George B. McClellan. WILLIAM ASTOR (1830–1892), brother of the above, became interested in Florida development, where a town was named for him. He built the first of the "Nourmahal" yachts and augmented the properties of his family. WILLIAM WALDORF ASTOR (1848–1919), great-grandson of the founder and son of John Jacob Astor 3rd, from whom he inherited $100,000,000, was born in New York city on March 31, 1848. From 1882 to 1885 he was U.S. minister to Italy. In 1890, after unsuccessful political attempts, he moved to England and became a naturalized citizen. His name is remembered by the building of the Waldorf-Astoria hotel in New York city. In 1917 he was created 1st viscount Astor. He died on Oct. 18, 1919.

His eldest son WALDORF ASTOR (1879–1952), who succeeded to the title, was born in New York city on May 19, 1879, and was educated at Oxford. In 1906 he married Nancy Witcher Langhorne (1879–1964) of Virginia, U.S., who in 1919 became the first woman member of the British parliament. Waldorf Astor was a member of parliament from 1910 to 1919. During World War I he was inspector in the quartermaster-general service. In 1915 he became proprietor of *The Observer*. He was private secretary to David Lloyd George (1918), parliamentary secretary to the ministry of foods (1918–19) and chairman of the Royal Institute of International Affairs (1935–49). He died on Sept. 30, 1952. The younger son of the 1st viscount Astor JOHN JACOB ASTOR (1886–) was born May 20, 1886, and educated at Oxford. He served as aide-de-camp to the viceroy of India (1911–14) and with the British army in World War I. In 1922 he became chief owner of the *Times* Publishing company. He was a member of parliament and director of railways and banks in England. In 1956 he was created baron.

In the American branch of the family, JOHN JACOB ASTOR 4th (1864–1912), great-grandson of the founder, was born in Rhinebeck, N.Y., on July 13, 1864, and graduated from Harvard in 1888. He built four of the largest hotels in New York city and several large office buildings and apartments. In the Spanish-American War he organized and equipped a battery which served in the Cuban campaign. When he died in the "Titanic" disaster on April 15, 1912, his fortune was estimated at $87,218,000. His son WILLIAM VINCENT ASTOR (1891–1959), born on Nov. 15, 1891, in New York city, attended Harvard and served in the U.S. navy in World Wars I and II. Under his direction the real-estate holdings of the family changed significantly. For the first time major portions of the Astor property in the heart of New York city were sold, including the site for the Empire State building. William Vincent Astor died in New York city on Feb. 3, 1959; most of his fortune was willed to the Astor foundation, a philanthropic agency he had established.

BIBLIOGRAPHY.—H. O'Connor, *The Astors* (1941); K. W. Porter, *John Jacob Astor, Business Man*, 2 vol. (1931); G. Myers, *History of the Great American Fortunes*, 3 vol. (1910). (J. R. LT.)

ASTOR, NANCY WITCHER, VISCOUNTESS (1879–1964), first woman to sit in the British house of commons, was born on May 19, 1879, at Danville, Va., the daughter of Chiswell Dabney Langhorne. In 1897 she married Robert Gould Shaw of Boston, Mass., from whom she obtained a divorce in 1903, and in 1906 she married Waldorf Astor, great-grandson of John Jacob Astor (1763–1848). When her husband succeeded to the viscountcy and thus relinquished his seat in the commons, Lady Astor, who had been his constant comrade-in-arms in his constituency at Plymouth, was adopted as Unionist candidate in his place, and after a stirring campaign was elected by substantial majority on Nov. 28, 1919. Lady Astor was returned for Plymouth at subsequent general elections until her retirement from parliament in 1945. A sympathetic and tireless champion of women's interests, she arranged as soon as she entered parliament for a deputation to interview the prime minister on the subject of women's pensions. She advocated the amendment of the legitimacy laws, and the equal guardianship of children; and in 1924 supported the Guardianship of Infants bill, which became law in that year. Lady Astor served on the joint select committee of both houses of parliament for the consideration of criminal law amendment, and on the home office committee on the employment of women in police duties in Feb. 1920. Apart from questions relating exclusively to women, her chief parliamentary work was done for a progressive educational policy, for temperance and for the extension of the Trade Boards acts. She constantly advocated the raising of the school-leaving age, and in 1923 carried through the Intoxicating Liquor (Sale to Persons under 18) bill. She also maintained a continuous agitation for improved conditions in certain branches of the distributive and catering trades. No less potent was her role as hostess at Cliveden, the Astors' country house, where she maintained a *salon* that exercised considerable influence in many fields, notably foreign affairs. All in all her vitality, trenchancy, courage, and gaiety made her one of the noteworthy figures of her generation. She was created a companion of honour in 1937. She died at Grimsthorpe castle, Lincolnshire, on May 2, 1964.

See M. Collis, *Nancy Astor: an Informal Biography* (1960). (H. G. N.)

ASTORGA, EMANUELE GIOACCHINO CESARE RINCON, BARON D' (1680–*c.* 1757), Italian composer, known for his dignified and pathetic *Stabat Mater* and for his chamber cantatas, of which about 170 survive. He was born at Augusta, Sicily, March 20, 1680, of noble family. His first opera, *La moglie nemica*, was performed privately at Palermo in 1698. Later he quarrelled with his father and left home. In Rome he met Sebastiano Biancardi, whose *Rime* (1732) contains valuable information on Astorga. At Genoa in 1709 poet and composer were robbed and the opera *Dafni* was written to raise money. After adventures under an assumed name Astorga was summoned to Barcelona by Charles III, Austrian claimant to the Spanish throne. Charles became emperor in 1711 and Astorga lived for a time in Vienna. When his father died in 1712 the family estates were sequestrated; Astorga reclaimed them in 1715, and settled at Palermo, where he married and became a senator, but in 1721 he left in unexplained circumstances after restoring his wife's dowry. Between 1721 and 1726 he was in Lisbon; according to Sir John Hawkins, the musical historian, he then went to London, en route to Bohemia. In 1744 his estates were sold to pay his wife's debts. According to a note on a manuscript he died in Madrid in 1757.

See H. Volkmann, *Emanuele d'Astorga*, 2 vol. (1911–19); O. Tiby *Emanuele d'Astorga: Aggiunte e correzioni da apportare alle ricerche del prof. Hans Volkmann* (1952). (FR. WA.)

ASTORIA, a city and a port of entry, the seat of Clatsop county, Ore., U.S. Located on the south bank of the Columbia river, 12 mi. from the open sea, it commands a spectacular view of the wide estuary. Its harbour facilities, under a port manager handle grain, lumber and general merchandise. Fishing, lumbering, pulpwood manufacture, dairy and diversified farming are its main industries. The city was chartered in 1867, and adopted a council-manager form of government in 1923.

Astoria is the site of the oldest settlement in Oregon. In 1805 the Lewis and Clark exploring party wintered on the nearby river which bears their names. In 1810–11 John Jacob Astor sent out sea and land parties to establish Fort Astoria (1811) as a depot for the Pacific Fur company's Indian, Russian, Alaskan and China trade. Two years later, war between the United States and Great Britain cut off its supply ships and the fort's trading stock was sold to the company's Canadian rival, the North West company. The same year a British man-of-war took possession of the fort, renamed Fort George. In subsequent peace negotiations, the site was restored to the United States, but Americans did not again occupy it until the mid-1840s. In 1847 the first post office west of the Rocky mountains was established in Astoria. A disastrous fire in 1922 destroyed most of the city's business district. Rebuilt, Astoria failed to recapture industries favourable to population growth, except during World War II when Tongue Point naval station was activated. Its population peak was reached in 1920 with 14,000. For comparative population figures *see* table in OREGON: *Population*. The 125-ft. Astor column and the Fort Clatsop National Memorial commemorate the historic past of the city and its surroundings. (D. O. J.)

ASTRAEA, in ancient Greek mythology, the "star maiden," daughter of Zeus and Themis, or of Astraeus the Titan and Eos ("the dawn"), in which case she is identified with Dikē. During the golden age she remained among men distributing blessings, but when the iron age began, she left the earth in disgust and was placed among the stars as the constellation Virgo. She is represented with a pair of scales and a crown of stars.

ASTRAGALUS, a very large genus of the pea family (Leguminosae [*q.v.*] or Fabaceae), widely distributed throughout the world, except in Australia, but most numerous in the steppe region of northern Asia, the high plains of western North America and the tropical Andes. The common species of the eastern United States, Canada and Great Britain are called milk vetch. They are mostly low herbs, though some are shrubby, with leaves usually divided into many narrow leaflets. *Astragalus* contains about 1,600

species. More than 275 of these are found in North America, 95% occurring west of the Mississippi river.

Although in number of species *Astragalus* ranks among the largest of plant genera, only a few are of economic importance. Gum tragacanth is derived from *A. gummifer* and other related low spiny shrubs native to Asia Minor. In Iran a sort of manna is obtained from *A. florulentus*. In northern Europe *A. boeticus* is cultivated for its seeds, which are used as a substitute for coffee, sometimes called Swedish coffee. The long roots of *A. aboriginum*, which occurs from Saskatchewan to Alaska and southward to British Columbia, Nevada and Colorado, are used for food by the Crees and other North American Indians. In the plains region of the United States, extending from Nebraska and Wyoming southward to Texas and New Mexico, *A. mollissimus* and other related species, called locoweed, are poisonous to grazing animals. Many highly ornamental old-world species of *Astragalus* are in cultivation, and several native to North America are sparingly planted.

ASTRAKHAN, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies in a long relatively narrow strip along the lower Volga, from just below Volgograd to the Caspian sea. Pop. (1959) 702,000. Area 17,027 sq.mi. The axis of the *oblast* is the floodplain of the lower Volga and its parallel distributary, the Akhtuba. The floodplain, with marshes, groves of trees and meadows is cut up by innumerable arms of the rivers and oxbow lakes. Soils are a fertile alluvium. The Volga and Akhtuba terminate in a large delta of sluggish distributaries and stagnant or semistagnant lakes, with wide areas of reeds and enormous numbers of wild birds, especially pelicans, herons, ducks, geese, swans, sea gulls and cormorants, and also the lotus (*Nelumbium caspicum*). A reserve was established in the delta for the protection of the wild life. Outside the belt of floodplain and delta the oblast consists of dry steppe in the northwest, giving way toward the Caspian to semidesert. There are extensive areas of bare, shifting sand dunes, many salt lakes and frequently saline soils. There is only a sparse vegetation of sage, although in places attempts have been made to fix the sands by plantation. The climate is dry, with an annual rainfall of only 8–9 in. Average temperatures are 19° F. for January and 77° F. for July.

In the lower Volga region the capital of the Tatar khanate of the Golden Horde was located at Sarai and later at Astrakhan city. In 1556 Ivan the Terrible captured Astrakhan and Russian colonization followed, pushing out most of the previous Kalmuck (Kalmyk) population. Many Russians and Ukrainians migrated there in the late 19th century. Most of the population is concentrated along the fertile floodplain and in the delta; about 52% are urban, living mainly in the administrative centre of Astrakhan.

Fishing is the major industry of the *oblast*, particularly in the delta and along the Caspian shores. Sealing has been carried on for over two centuries. Agriculture is concentrated almost entirely in the floodplain, where melons, tomatoes, vegetables and fruit are grown. Floods, however, restrict the area that can be cultivated. Cattle and sheep rearing is carried on in the steppe and semidesert areas. Salt is obtained from Lake Baskunchak, near Vladimirovka. Industry is mainly food processing and canning, in Astrakhan city and a number of smaller places. A large volume of trade, especially in oil and timber, uses the Volga, while railways run from Astrakhan south to Baku and along the Volga to Volgograd (Stalingrad) and Engels. (R. A. F.)

ASTRAKHAN, a town and the administrative centre of Astrakhan *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., is situated in the delta of the Volga, 62 mi. from the Caspian sea. It lies on several islands on the left bank of the main (westernmost) stream of the Volga. Pop. (1959) 294,000, is of mixed character, with Russians, Armenians, Tatars, Jews, Kalmyks (Kalmucks) and Kazakhs. The town's greatest importance is as a port and transshipment point, petroleum and timber being the major cargoes handled. The actual river port is in the town itself, but, because of the extreme shallowness of the Caspian off the Volga delta, sea-going craft have to transship at the 12-Foot Roads about 45 mi. out in the Caspian sea and 125 mi. from Astrakhan, which is reached by a dredged channel. A railway from the town runs parallel to the Volga to Volgograd (Stalingrad) and Engels, while another line runs to Baku. The town is the base of a large fishing fleet and it is important as a fish canning and caviar-preserving centre. Food processing is the chief industry and includes meat and vegetable canning. Other industries are the manufacture of cotton, woolen and leather goods, and boots and shoes, ship-repairing and cooperage. Astrakhan fur, which comes from the karakul lamb of central Asia, is named after the town because it was first brought to Russia by Astrakhan traders.

Astrakhan was formerly the capital of a Tatar khanate, a remnant of the Golden Horde, when it was located on the higher right bank of the Volga. It was captured in 1556 by Ivan IV ("the Terrible") and two years later it was moved to its present site, as being more easily defensible. The kremlin, built shortly afterward, is still in existence. Thirty-one bridges link the different parts of the town. There are medical and pedagogical institutes and a technical institute of fisheries and the food industry. (R. A. F.)

ASTRINGENT, a term comprising a group of agents that tend to shrink mucous membranes and raw surfaces and to dry up secretions. They are usually classed according to their mode of action into: (1) those that decrease the blood supply by narrowing the small blood vessels (adrenaline and cocaine are in this group); (2) those that abstract water from the part, as glycerin and alcohol; and (3) those that coagulate the superficial layers and form a crust, as the metallic astringents. They are used in medicine to reduce swollen mucous membranes in inflammations of the nasal, alimentary and urinary passages. They are frequently employed in attempts to dry up excessive secretions and to stop the oozing of blood.

ASTROLABE, an instrument used for the taking of altitudes of celestial bodies, from which time and latitude are deducible. The planispheric astrolabe, to which the name is commonly restricted, is believed to have been a Greek instrument invented by Hipparchus (150 B.C.), or even by Apollonius of Perga (*c.* 240

AUTHENTICATED NEWS

BRASS ASTROLABE MADE IN 1462 BY REGIOMONTANUS, GERMAN ASTRONOMER KNOWN ORIGINALLY AS JOHANN MÜLLER

Face view showing the alidade, or sight rule, and the *rete*, or star map

B.C.). It was revived by Prof. Charles Jenkin of Oxford as a useful educational instrument, so with a history of 2,000 yr. it may claim to be the oldest scientific instrument in the world, and has played a correspondingly important part in the history of civilization. Seamen from the time of Martin Behaim (*c.* 1480) to the middle of the 18th century, when the astrolabe and cross-staff were superseded as navigational instruments by John Hadley's reflecting quadrant (*see* SEXTANT), relied largely upon such instruments and tables of the sun's declination for finding their latitude.

In its most usual form it consisted of an evenly balanced circle or disk of metal or wood, hung by a ring and provided with a rotatable alidade or a diametral rule with sights, turning within a circle of degrees, for measuring the altitudes of sun or stars. On the back was a circular map of the stars, the *rete,* often beautifully designed in fretwork cut from a sheet of metal, with named pointers to show the positions of the brighter stars relative to one another and to a zodiacal circle showing the sun's position for every day of the year. Lying below the *rete* were one or more interchangeable plates engraved with circles of altitude.

To obtain the time, the user first measured the altitude of the sun, then, having noted the sun's position for the day in the zodiacal circle, rotated the *rete* until the sun's position coincided with a circle on the plate corresponding to the observed altitude. A line drawn through this point of coincidence and the centre of the instrument to a marginal circle of hours showed the time.

Among the accessories often introduced in the earlier astrolabes were shadow scales, for simple surveying and measuring heights and distances; calendar scales showing the sun's place in the zodiac for every day of the year; magnetic compasses, usual in instruments of the 16th and 17th centuries; and various lines and tables of use to astrologers.

See Robert T. Gunther, *The Astrolabes of the World* (1932); Derek J. Price, "Precision Instruments: To 1500," in Charles Singer *et al., A History of Technology,* vol. 3 (1957). (R. T. G.; X.)

ASTROLOGY is the art or science which claims to forecast events on earth by observation of the fixed stars and of the sun, moon and planets. It originated in Mesopotamia, perhaps in the 3rd millennium B.C., but attained its full development only much later, within the orbit of Greek civilization of the Hellenistic period. In its older Mesopotamian form it spread to India in the 6th century B.C. and reached China not long after. It is probable, however, that only the idea of prognostication by the stars was adopted in China and not the specifically astronomical knowledge, which seems to have had an independent development there. In its fully developed Greek form astrology was a vast, complex and apparently scientific system which for about 2,000 yr. exerted a dominant influence on the religion, philosophy and science first of pagan and then of Christian Europe. Islamic culture likewise absorbed it as part of the Greek heritage; and in the middle ages, when western Europe was strongly affected by Islamic science, astrology also acquired an Arabian colour.

Astrology in Mesopotamia and in Egypt.—In Mesopotamia the magicians and astrologers practised divination in two ways. In the first, they scrutinized the livers of sacrificial sheep for omens likely to concern the king or his kingdom. In the second and, eventually, far more important method, omens were drawn from celestial phenomena. Systematic observation of the celestial bodies was begun, records were kept and arithmetical procedures were developed to correlate these data. Believing, as they did, that the heavenly bodies were powerful gods, the astrologers began to associate with their belief this growing body of astronomical knowledge, which constitutes the earliest exact science known to history.

The Greek astronomer Ptolemy says that Mesopotamian records of eclipses were available from a date expressed as 747 B.C., and excavation confirms that early in the 1st millennium B.C. accurate knowledge existed of the sun's annual course, of the phases of the moon and of the periodicities of certain planets. It was on this combination of religion and science that the astrologers based their prognostications; and it was this form of divination, roughly corresponding to what was called mundane astrology in later times, that spread to India and China and also provided a starting point for later Greek developments. Astrology's original association with the ruling family explains its title of the royal art.

The Egyptians also contributed, though less directly, to the rise of astrology. They constructed a calendar of 12 months of 30 days each with five days added at the end of the year. This calendar, which avoids all the irregularities of lunar or lunar-solar calendars, was taken over by the Greeks as a standard of reference for astronomical observations and has proved of great historical importance. Another of their contributions is of more mixed quality. In order that the starry sky might serve them as a clock, the Egyptians selected a succession of 36 bright stars whose risings were separated from each other by intervals of ten days. These stars, which served to indicate the time throughout the year, came to be called *decans* by Latin writers. Each of them was conceived of as a spirit with power over the period of time for which he served; and when these 36 *decans* later entered the zodiac (*q.v.*) as subdivisions of its 12 signs they signally contributed to that conception of a different quality for each moment of time which is characteristic of astrology. The Greek term *hōroskopos,* from which the word horoscope is derived is, in one of its meanings, a synonym for "decan star."

Greek Speculation and Catasterism.—The fact that men discover signs of future events in the stars does not necessarily mean that they believe the stars cause these events. But before the Greeks learned astrology from the Mesopotamian priests the development of their own speculation had strongly inclined them toward this view. Basing their thought on such obvious phenomena as the dependence of the earth upon the sun for its life-giving heat, various schools taught the view that the divine source of terrestrial happenings was situated in the sky. When the astral gods of Mesopotamia were introduced to the Greeks in the 4th century B.C., many leaders of thought embraced them eagerly. Greek planetary lore was derived from Mesopotamia, and the Mesopotamian planets, as already seen, were not only stars but gods. The Greeks were at this time making rapid advances in astronomy by the application of new geometrical techniques, and were thus ready for the view that their growing knowledge of the motion of the stars was identical with a growing knowledge of the divine. Many were also ready for the further idea that the stars not only indicated but caused terrestrial events.

But long before the 4th century B.C. the fertile popular imagination of the Greeks had peopled the world with a host of gods in human shape, who had little or nothing to do with the stars. These gods of the popular imagination were more powerful than men and exempt from death, but in all else they were human. They were male and female, young and old; they ate and drank; they fought and loved; they married and begot children. Furthermore, they were enshrined in a rich national literature and worshiped in innumerable cults. Philosophers, in turning toward the star-gods, could not abolish the gods of popular belief; by choice or by necessity they identified the two. Plato, in the middle of the 4th century B.C., proposed as the supreme object of worship for the state which he outlined in his *Laws* a composite god, Apollo-Helios. By this means he united the god of mythology, the patron of Delphi and Delos, with the sun. His contemporary, the astronomer Eudoxus, was similarly engaged in a process known as catasterism; *i.e.,* the identification of the stars with the personages of mythology. Later astronomers continued the task. The Greek heavens assumed a dual character. The astronomers not only revealed the celestial bodies as wheeling eternally in their circular orbits according to the laws of Greek spherical geometry; they also showed them palpitating with the life and passions of the familiar anthropomorphic gods. By a slow process of cultural evolution the mentality had been prepared which would trace in the physical and mental constitution of individual men and in every detail of their lives the effect of starry influences. The astrological age was about to be born. The old mundane astrology of Mesopotamia was about to be transformed into the personal astrology of Hellenistic Greece.

The Zodiacal Belt and the Horoscope.—In the casting of a person's horoscope everything depends on the determination of

the configuration of the heavens at the moment of his birth. In this calculation the zodiacal belt plays the leading role; for the history of astrology it is therefore of supreme importance to determine the date when the belt was invented. In antiquity, practitioners of the art had an interest in putting this date as far back as possible, and extravagant claims were made that the Chaldeans, or Mesopotamian star-clerks, had had knowledge of the zodiac tens or even hundreds of thousands of years before. Modern scholarship does not support this view, but suggests rather that the constitution of the zodiacal belt was an achievement of Greek science slowly perfected over several centuries.

Pliny ascribes the first steps to Anaximander and Cleostratus in the 6th and 5th centuries B.C. But the tracing out of the annual path through the constellations of the sun with its attendant planets, the division of the belt into 12 signs of 30° each and the tailoring of the older constellations to fit so far as possible into the 12 signs was an enterprise probably carried out in stages. On its completion might well have depended the discovery by Hipparchus in the 2nd century B.C. of the precession of the equinoxes (*q.v.*). The divisions of the year governed by the 12 signs are as follows:

Aries, the Ram March 21–April 19	Scorpio, the Scorpion Oct. 24–Nov. 21
Taurus, the Bull April 20–May 20	Sagittarius, the Archer Nov. 22–Dec. 21
Gemini, the Twins May 21–June 21	Capricornus, the Goat Dec. 22–Jan. 19
Cancer, the Crab June 22–July 22	Aquarius, the Water Carrier Jan. 20–Feb. 18
Leo, the Lion July 23–Aug. 22	Pisces, the Fishes Feb. 19–March 20
Virgo, the Virgin Aug. 23–Sept. 22	
Libra, the Balance Sept. 23–Oct. 23	

These divisions are still adhered to, despite the gradual loss of correspondence between the signs and the actual constellations due to precession.

In the elaboration of their scheme the Greeks were indebted to the Mesopotamians for their records of planetary motions, and there is evidence that by the 5th century the Mesopotamians had some idea of the belt. Already at this date Greek and Mesopotamian astronomy were influencing each other. Nevertheless, the zodiac is a product of Greek geometry rather than of Mesopotamian arithmetic.

It was in the 3rd century that the Mesopotamian practice of divination by the stars was introduced to the Greeks. If the special mental climate of Greek civilization be borne in mind (*i.e.*, the effect of the intimate blending of the Greeks' own personal gods with the borrowed astral gods, and the intellectual prestige given to this new religious conception by the brilliant new geometrical astronomy with which it was combined), it can be readily understood that the Greeks transformed astrology into something unknown in the land of its origin. In Mesopotamia, astrology had been a royal institution in which omens concerning the welfare of king and country had been drawn from signs in the sky. With the Greeks it became a supposedly scientific means of ascertaining the future, and its use was no longer confined to heads of state but extended to give personal information concerning his character and his future career to every individual who cared, or who could afford, to pay for it. The system was illusory, but in this illusion were involved the speculative thought and the scientific achievement of a uniquely gifted people.

It is in the 2nd century B.C. that evidence of this personal, or genethlialogical, astrology is first found; the first known textbook came from Ptolemaic Egypt and dates probably from the end of that century. For the casting of an individual horoscope it is necessary to determine the configuration of the heavens at the moment of birth, and the ascendant, *i.e.*, the point where the ecliptic intersects the eastern horizon at that moment, marks the start of the whole calculation. A chart of the heavens is completed in which the positions of sun, moon, planets and constellations are plotted. Their influence on the newborn child is deduced from the mythological character of the celestial bodies, and this influence is modified by the geometrical relationship between them; *i.e.*, by their relative positions in conjunction, in opposition, in quintile, sextile or other aspects. The sun, moon and planets, being living beings, had their preferred situations or abodes among the stars. These are referred to as houses. The influence of the planets is therefore further modified by these houses. According to one system the zodiacal belt was divided into 12 such houses, and these were ingeniously allotted to the seven competing tenants on the assumption that the sun, who gives light by day, and the moon, who gives light by night, need only one house each, while the other five planets need two houses each, one for use by day, the other for use by night. Another arrangement of 12 houses was made by means of a geometrical construction, starting from the point of intersection of the ecliptic and of the horizon, which divided the whole sphere of the fixed stars (not merely the zodiacal belt). To these houses, however determined, were assigned the several departments of human life, the planets of the various houses giving information about the matters pertaining to their sphere of influence, such as wealth, dignities, marriage, children, friendship, enmities or death.

Scientific Acceptance of Astrology by Greeks and Romans.—By such arbitrary correspondences was it made possible, and plausible, to elicit from the motions of the stars advance information about all the circumstances of life. It may seem inconceivable that so great a man as Hipparchus, one of the greatest in the history of science, should support and encourage this delusion. His intellectual climate must be remembered. The number mysticism of the Pythagoreans and the astral theology of Plato offered a prepared foundation for the erection of the astrological system and, in a world in which small political units with their local gods were being absorbed into great empires, the stars formed an object of worship acceptable to all. As the psalmist said of them, "There is no speech nor language where their voice is not heard." Of the two great philosophical schools which divided the allegiance of later centuries the Epicureans, it is true, rejected the astral gods and fought the astrological illusion, but the Stoics, who proved the more influential in ruling circles, accepted it from the first, strengthened it by their firm logic and preached it with fervour.

Once established, the astrological conception of causation invaded all the sciences. Medicine with its allied disciplines affords the most instructive example of this process. To the believer it appeared obvious that the mental and physical constitution of a man, as well as his fortune, was determined by the configuration of the heavens at the moment of his birth, for that was the decisive moment when the tender new life was fully receptive to the manifold influences raining down upon it from the great gods of the sky.

The Stoics' doctrine of a universal "sympathy" linking the little world of man, the microcosm, with the great world of nature, the macrocosm, was illustrated by astrology, which provided a picture of the process at work. A new branch of astrology, *melothesia*, put each limb, each organ, each function of the human body under the domination of the several planets and of the signs of the zodiac. Thus the concepts of planetary man and of zodiacal man created a pseudomedicine which continued at least until the 17th century A.D. to confuse the true science. Botany, zoology and mineralogy suffered the same fate as medicine.

When the Romans began to absorb Greek culture they did not at once welcome astrology. They had their own native methods of divination, and the established soothsayers and augurs resisted the innovation. At the close of the republic not only the Epicurean poet Lucretius but also his great opponent Cicero rejected astrology. But Nigidius Figulus, the most learned man of their generation, supported it and introduced to the Romans both the Greek zodiac and the Egyptian *decans*, the *sphaera graecanica* and the *sphaera barbarica*. With the empire, astrology triumphed. Augustus favoured the older conception of the art as a royal prerogative; or so may be interpreted Virgil's allotment to him of a place among the stars and the astrological design of the Pantheon, first erected by Agrippa, his minister of public works. To Augustus' age also belongs the beginning of the full exposition of the art in all its aspects by the poet Marcus Manilius. As a police measure astrologers (*mathematici*) were repeatedly banished, their influence on the fickle populace being feared, but the addiction of

later emperors (Tiberius, Nero) to the superstition and its persistence among the masses is abundantly supported.

Astrology in the Christian World.—The reception of astrology by Christianity is a most curious page in its history. As against the omnipotence of the stars Christianity taught the omnipotence of their Creator. To the determinism of astrology Christianity opposed the freedom of the will. But within these limits the astrological world view was accepted. To reject it would have been to reject the whole heritage of classical culture, which had assumed an astrological complexion. It was in the 2nd century A.D. that Ptolemy summed up in his *Almagest* the whole achievement of ancient astronomy; yet, as his extant *Tetrabiblos* shows, he was a determined astrologer, defending the system with a zeal beneath which the modern reader may perhaps detect evidence of embarrassment and even of bad faith. So compelling at this period was the astrological view. But evidence of the criticism to which Christianity subjected it may be found in a terminological change which took place at this time. Throughout pagan antiquity the words astronomy and astrology had been synonymous terms; in the first Christian centuries the valuable modern distinction between astronomy, the science of the stars, and astrology, the art of divination by the stars, began to appear. But though various Christian councils condemned astrology, the belief in the world view it implies was not seriously shaken. The persistence of the astrological week with its seven days named after the sun, moon and planets, and the choice of an astrological date for Christmas are examples of its power.

The overthrow of the western empire involved a decline of astrology. But it revived with Charlemagne, and then, with the spread of Islam into Europe, became dominant in every department of knowledge. Up to the 12th century, knowledge of the art in western Europe had depended on late Latin (5th century) sources like Macrobius. After this date the original Greek sources, enriched by their Arab commentators, became available in Latin translations often made by Jewish scholars familiar with both the Islamic and the Christian worlds.

The strength of astrological ideas in 13th century Europe is shown by the fact that both Dante and St. Thomas Aquinas admit into their Christian philosophy a modified form of the astrological conception of causation. Great princes and prelates now again begin to have astrologers to advise them. In the 14th century a number of universities, among them Paris, Padua, Bologna and Florence, had chairs of astrology. The revival of ancient studies by the humanists only encouraged this interest, which persisted into the Renaissance period. Nor did the Reformation bring any change. Melanchthon, Tycho Brahe and Kepler all accepted the astrological world view.

The Decline of Astrology.—The study of such a pioneer of modern science as Kepler throws light upon the mentality of the great scientific astrologers of the preceding 2,000 yr. Hipparchus, who laboured in the tradition of his Greek and Mesopotamian predecessors to discover the precession of the equinoxes; Ptolemy, who on the basis of Hipparchan astronomy created the system which goes by his name and which was only superseded after 1,500 years by that of Copernicus; Kepler, who worked on materials accumulated by Tycho Brahe to arrive at his theory of planetary motion; all were astrologers as well as scientists. But it is certain that, with the ancients as with Kepler, the casting of horoscopes took second place to philosophic and scientific interests. Impatience with the superstitious aspect of astrology is natural, but it is still possible to be moved by the spectacle of Kepler's excusing himself from the labour of casting horoscopes in order to save time for his scientific work, and of his sustaining himself in his lifelong endeavour by the conviction that to solve astronomical problems was to enter into the very mind of the Creator and discover truths which must serve both to unite all mankind and raise the individual above his selfish personal concerns. At the dawn of the 19th century, when astrology had become an exploded superstition, Friedrich Schiller, engaged in writing his tragedy of *Wallenstein*, was embarrassed at the prospect of putting on the stage a figure so ridiculous as that of the astrologer whom the historical Wallenstein had kept in his employ, until Goethe reminded him of the nobler aspects of a belief which could once commend itself to great minds as the perfect blend of religion and science.

As a popular pastime or superstition, however, astrology still engages the attention of millions of civilized people, this interest being catered for by articles in the daily press, by special almanacs and by manuals, large and small, devoted to various aspects of the subject. But, as a serious and systematic world view claiming the allegiance of many of the best intellects in every rank of society, astrology is dead. If it be asked what dethroned astrology the answer lies in the general progress of science and scholarship. Astrology had been born in a geocentric world, and the Copernican revolution dealt it a shattering blow. The predictions of the astrologers do not survive the test of the experimental method. Scholarship, in its concern with the history of ideas, shows how easily genuine elements of knowledge can combine with illusory notions to form grandiose systems of thought in which the mind is content to dwell for a time.

ASTRONOMY (ARTICLES ON). The article ASTRONOMY reviews the role of this science in the history of civilization, its insights into the nature of the universe, and the development of its methods for bringing the investigation of celestial bodies within the scope of the laboratory.

ASTROPHYSICS describes the techniques by which the light emanating from the outer layers of the heavenly bodies is used as raw material for the extraction of significant information.

COSMOGONY discusses various concepts of the evolution of the universe, or the origin of individual galaxies, stars, planetary systems and satellites, and of the elementary particles of which these bodies are composed. COSMOLOGY deals with efforts to explain the constitution and dynamics of the universe by organizing the available data into a logical pattern. The points of view represented in this article range from the mythological cosmos of the ancients to such post-Einsteinian models as the steady state theory, which postulates a still-continuing process of the creation of matter.

GALAXY describes the rotating system of stars within which the sun and its planets, including the earth, are located, and around the centre of which the sun revolves in a "cosmic year," or period, of approximately 200,000,000 earth years. NEBULA describes the study of other galaxies with the help of light that in some instances started from its source hundreds of millions of years ago.

STAR discusses the visual and physical properties of these remote suns; similarly, STAR CLUSTER treats of the groups of stars that are considered to have a common physical origin. The variable stars are discussed in NOVA AND SUPERNOVA; and many articles are devoted to individual stars, such as ALDEBARAN, BETELGEUSE and SIRIUS. The visual patterns of groups of stars and nebulae are treated in CONSTELLATION and in articles on individual constellations, such as ANDROMEDA, CASSIOPEIA, ORION.

The dwarf star around which the earth revolves has been studied from many points of view, ranging from its subatomic particles to prominences extending at times 500,000 mi. into space; the findings of these studies are presented in SUN.

Among the articles devoted to other bodies in the solar system are ASTEROIDS; COMET; METEOR; MOON; PLANETS; and the articles on individual planets, including EARTH. The minuscule but significant particles of unknown origin that are sparsely distributed through outer space are discussed in INTERSTELLAR MATTER. METEORITES treats of the extraterrestrial objects that constitute a material link between the chemistry of our planet and other planetary bodies.

The conjectures of astronomers concerning the possibility of life on planets other than the earth are presented in a section of COSMOGONY under the caption *Origin of Planetary Systems;* in *Habitability of the Planets,* in PLANETS; and in MARS.

Articles on astronomical phenomena include: ABERRATION (OF LIGHT); AURORA POLARIS; CHROMOSPHERE; CORONA; ECLIPSE; ORBIT; PARALLAX; PRECESSION OF THE EQUINOXES; QUASI-STELLAR RADIO SOURCES; ZODIACAL LIGHT; etc.

Articles dealing with astronomical equipment and techniques include ASTROLABE; CELESTIAL MECHANICS; EPHEMERIS; OBSERVATORY (ASTRONOMICAL); PHOTOGRAPHY, CELESTIAL; PHOTOMETRY, CELESTIAL; PLANETARIUM; RADIO ASTRONOMY; SEXTANT; SPECTROHELIOGRAPH; SPECTROSCOPY, ASTRONOMICAL; TELESCOPE; TELESCOPE, RADIO; etc. Some of the familiar applications of astronomy are discussed in CALENDAR; NAVIGATION; SUNDIAL; TIME MEASUREMENT; and TIME, STANDARD.

ASTROLOGY and ZODIAC deal with the great visual configurations of the heavens in terms of the body of legendary pseudoscience that is related to astronomy as alchemy is to chemistry.

Much of the knowledge of the earth and phenomena affecting it is derived from the growing collaboration between astronomical and terrestrial studies. Among the articles concerned with various phases of this interrelationship are: COSMIC RAYS; GEOCHEMISTRY; GEODESY; SPACE EXPLORATION; QUANTUM MECHANICS; RELATIVITY; SPACE-TIME; TIDE; and LIGHT, VELOCITY OF.

Many biographical articles help set in perspective the work of the great astronomers, from ARISTARCHUS OF SAMOS, the first man known to have reasoned that the earth revolves around the sun, to such modern pioneers as EDDINGTON, SIR ARTHUR STANLEY; HALE, GEORGE ELLERY; RUSSELL, HENRY NORRIS; and SHAPLEY, HARLOW.

ASTRONOMY deals with the origin, evolution, composition, distance and motion of all bodies and scattered matter in the universe.

Astronomy is the most ancient of sciences, having existed since the dawn of recorded civilization. Because it is essentially a nonutilitarian science, few practical uses have been found for it, but those uses have been of primary importance. As long ago as 2000 B.C. the Egyptians and Babylonians were using calendars based on the regularity of certain astronomical events. In later years, astronomy was utilized in telling precise time, locating the positions of ships at sea and geographical features on land, predicting seasons of the year and, more recently, computing the orbits of artificial satellites.

This article is divided into two main sections. The first section traces the historical development of astronomy and the second discusses modern descriptive astronomy. The material in the two sections is arranged under the following main headings:

I. HISTORY OF ASTRONOMY

The development of astronomy can be divided into three periods: (1) Ancient astronomy, dating from the first significant contributions of the earliest civilization to the *Almagest* of Ptolemy; (2) medieval astronomy, from the decline of Alexandrian culture to the Renaissance; (3) modern astronomy, from the Copernican revolution to the present time; and overlapping it the new astronomy of astrophysics, mainly a product of the 20th century.

A. ANCIENT ASTRONOMY

1. Mesopotamia.—Much of the ancient knowledge of the celestial bodies and their ways is frequently credited to people who dwelt in the valleys of the Euphrates and Tigris rivers, the region that is now Iraq. These were the Babylonians, Assyrians and Chaldeans, and before them a pre-Semitic population, the Sumerians. Some confusion is avoided by referring to them all as the Babylonians. Our understanding of what these people learned about the heavens comes partly from the recovery from the sites of their cities of texts inscribed by their priests in cuneiform script on clay tablets. Some of their astronomical lore is identified in information they seem to have transmitted to neighbouring peoples, particularly the early Greeks.

The world viewed by the Babylonians is presumed to have consisted of a disk-shaped earth surrounded by a moat of sea beyond which the inverted bowl of the sky came down all around. It had similarities to the sort of world portrayed later in the *Iliad* of Homer. The story of creation recited in some of their tablets suggests the belief that the dry land emerged by supernatural means from the waters of the sea. There was also the account of a great flood that threatened to return the land to the sea. The celestial bodies rose over the rim of that world, moved across the sky, and set.

Although the stars always remained in fixed formations, seven planetary bodies moved among the stars, thus demonstrating their importance. The sun, moon, and five known planets were believed to be gods whose movements could reveal their intentions concerning the world and its people.

It was the duty of the Babylonian priest-astrologers to watch the seven wandering bodies so that they might predict and warn the king of any disasters the gods might be preparing for the nation. Such observations promoted knowledge of occurrences in the heavens; the interpretation of these observations required familiarity with constellations, particularly the constellations of the zodiac through which the planetary bodies moved. A second incentive for acquaintance with the heavens was the usefulness of celestial bodies in serving as guides to travelers through the desert and over the sea, in telling the time of day or night and in regulating a calendar.

People in Mesopotamia are believed to have recognized a number of prominent constellations as early as 3000 B.C. and to have named them after animals, such as the Lion, and representatives of certain occupations, such as the Herdsman. This plan was transmitted to the Greeks and, with changes of names and additions of other constellations, has descended to us. The Babylonians are credited with inventing the signs of the zodiac; these 12 divisions of equal size could serve better for describing the positions of the sun, moon and planets than could the 12 constellations of the zodiac of unequal lengths, for which the signs were named. These people seem to have recognized the precession of the vernal equinox, the point on the sun's path around the heavens from which the signs are marked off. They accordingly knew that the signs are shifting westward gradually with respect

to the corresponding constellations.

2. Egypt.—Ancient Egypt, where civilization began at about the same time as in Mesopotamia, devised the first solar calendar, in which the length of the year remained fixed at 365 days. From observations of the first appearance of the star Sirius (their Sothis) before dawn, an event with which the beginnings of the Nile floods were associated, the Egyptians learned that the length of the year is actually more equal to 365¼ days. This value was first employed for calendar purposes by Gaius Julius Caesar in his reform of the Roman calendar (*see* CALENDAR). The Egyptians' picture of the universe was less scientific than that of the Babylonians, being peopled with gods and goddesses. The sky itself was identified with the goddess Nut.

3. Greece and Alexandria.—Greek cosmology seems to have started with ideas comparable to those of the Babylonians. More rational ideas about the universe were held by Greek philosophers from Pythagoras (6th century B.C.) to Aristotle (384–322 B.C.). Our information about their thinking is derived mainly from Aristotle's *De caelo*. The earth came to be regarded as a globe, and proofs were given to support this view. Although Aristotle supposed that the earth was stationary, certain other philosophers believed that it was moving. Aristarchus of Samos (3rd century B.C.) is said to have advocated the earth's annual revolution around the sun and its daily rotation on its axis; but whatever he may have written on the subject has been lost. In the same century, Eratosthenes, librarian of the museum at Alexandria, determined the circumference of the earth with remarkable accuracy, considering the simple means employed.

The sky of the later Greek philosophers was a hollow globe surrounding the earth and having the stars set like jewels on its inner surface. The sky was supported on an axis thrust through the earth; on this axis the sky rotated westward daily, causing the celestial bodies to rise and set. This conception of a rotating celestial sphere persisted to the time of Copernicus and is useful as a convention today. There was then the necessity of accounting for the independent movements of the sun, moon and five planets, which changed their places among the stars. These wanderers were believed to move in the space between the earth and the celestial sphere at distances from the earth corresponding to the periods of their eastward revolution around the heavens. It was known that the sun and moon move nonuniformly, and that the planets also turn at intervals and retreat westward for a time before resuming the eastward progress.

By what combinations of uniform circular motions centred in the earth may the movements of the seven wanderers among the stars be represented? This famous problem was proposed not to explain celestial motions but to portray them by mathematical machinery. A successful plan could predict the places of these bodies among the stars at any time and also the times of occurrences such as eclipses of the sun and moon. One solution of

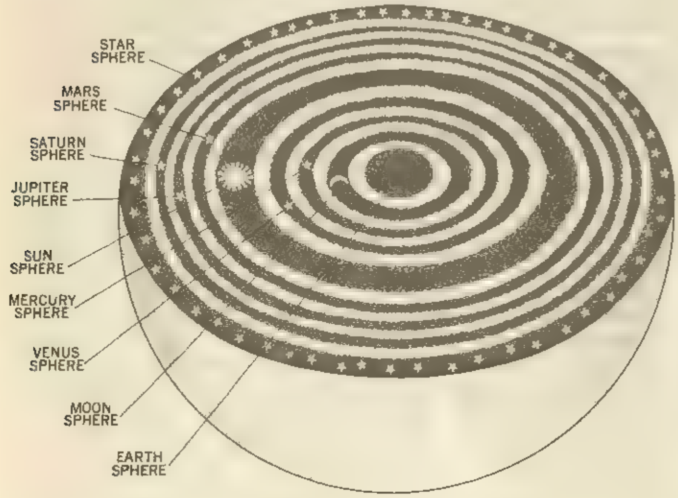

FIG. 1.—AN ANCIENT CONCEPTION OF THE SPHERICAL COSMOS

the problem was devised by the mathematician Eudoxus of Cnidus (4th century B.C.). Each body was moved by a set of rotating spherical shells connected by a sort of gimbal arrangement (see fig. 1). The outermost shell of a set was attached to the long axis on which the celestial sphere rotated; it gave the planet its daily westward motion along with the stars. The shell next inside turned slowly eastward on the first, imparting to the planet its principal motion among the stars. Other inner shells turning independently produced other movements. The planet itself was attached to the innermost shell of the set and partook of the motions of them all. This solution was adopted by Aristotle, who employed 55 shells in all, including the sphere of the stars. It accounted for the motions of the wanderers because they were not very accurately observed at that time, but it kept each planet always at the same distance from the earth and therefore could not explain its observed variation in brightness. As an example, the planet Mars is at times second only to Venus in brightness and at other times may not be much brighter than the pole star. Since it was unable to explain these and other occurrences, the first solution failed.

A more enduring solution of the problem of the seven wanderers was devised by another mathematician, Apollonius of Perga (3rd century B.C.), who worked mainly at Alexandria; he is also known for his treatise on the conics. His method was adopted by Hipparchus of Bithynia (2nd century B.C.), the most persistent observer among the Greek scholars. Hipparchus attempted to adjust the method to interpret the motions of the sun and moon, but had found the positions of the planets and stars observed by his predecessors too scanty and inaccurate for him to make much headway with the motions of the planets themselves. The records of his own observations provided the data with which Ptolemy was later able to put the whole plan in workable order.

Alexandria, founded in 332 B.C. by Alexander III, (the Great), was the centre of Hellenistic culture for several centuries. Its last distinguished astronomer was Ptolemy (Claudius Ptolemaus, 2nd century A.D.); he was the author of *Megale syntaxis tes astronomias*, later known to the Arabs as the *Almagest*. In this book Ptolemy explained in detail the geometrical interpretation of the celestial motions known as the Ptolemaic system. In the simplest form of the system, each planet moved in a small circle, the epicycle, in the period of its actual revolution around the heavens relative to the sun's place. Meanwhile, the centre of this circle moved eastward around the earth on a larger circle in the observed period of the planet's revolution relative to the stars. An alternative and less favoured method of eccentrics had the planet moving in a large circle whose centre circled around the earth. Such combinations of circular paths could produce the looped courses of the planets and the variable speeds of all seven wanderers. With initial conditions it would be possible to predict the positions of these bodies among the stars at any future time. If one of them was then not in the expected position, the plan could be revised by adding more epicycles or by making other changes in the specifications. It was hoped that the appropriate plan of celestial clockwork might be perfected by trial and error. *See* PTOLEMY; PTOLEMAIC SYSTEM; ALMAGEST.

B. MEDIEVAL ASTRONOMY

Greek astronomy, at least until its later years, was based mainly on philosophical thinking rather than observational data, and it made slow progress. It did, however, produce a rational picture of the universe that might be improved later, but any considerable improvement in the picture, except in the details of the Ptolemaic system, was to be delayed all through the dark ages. After the time of Ptolemy and especially after the fall of the Roman empire, the civilized world was to be divided between two movements: Christianity and Islam, that for many centuries were unfavourable to modification of the Greek picture.

Astrology, although banned by the Christian church, continued in strength in a form that the Babylonian priest-astrologers would scarcely have recognized. Theirs had been an astrology requiring attention to the heavens and leading to astronomical discoveries, whereas the post-Christian type was more concerned with divina-

tion than with observation. The scholasticism of these times led to neglect of other ways of thinking and, particularly at first, of the learning of the Greek scholars. People lived again on a flat earth under an inverted bowl of the sky.

The followers of Mohammed, who founded Islam in the 7th century A.D., needed observers to determine by sights on the stars the direction of Mecca from various parts of their dominions so that the faithful might face in these directions in their prayers. Several observatories were built for this purpose. The practical astronomers of Islam also employed their calculating skills to perfect the Ptolemaic system of the planetary motions. Their textbook was the *Almagest*, which they had translated into Arabic.

Toward the close of the middle ages, certain European rulers began to attract to their kingdoms Muslim and Jewish scholars, who introduced the use of Arabic numerals, divisions of the circle, and algebra. Some of these scholars were asked to translate the *Almagest* and other books on astronomy from the Arabic. King Alfonso X of Castile kept a number of scholars occupied for ten years constructing tables (the Alphonsine tables, *c.* 1270) for predicting positions of the planetary bodies. By this time each planet had been provided with from 40 to 60 epicycles to represent after a fashion its complex movement among the stars. Amazed at the difficulty of the project, Alfonso is credited with the remark that had he been present at the Creation he might have given excellent advice. After surviving for more than a millennium, the Ptolemaic system had failed; its geometrical clockwork had become unbelievably cumbersome and without satisfactory improvement in its effectiveness. The way was open for a new approach not only to the problem of the planetary motions but to that of the structure of the universe as well.

In the early part of the 16th century the scientific ignorance of Europe began to be lessened. Columbus had sailed far to the west to discover the new world; he had not fallen into an abyss beyond the edge of the world, nor had he been destroyed by monsters reputed to operate in that vicinity. The companions of Magellan had returned from their voyage around the world. Johann Gutenberg's invention, in the mid-15th century, of printing from movable type gave wider dissemination to the works of Aristotle and other classical scholars. Copernicus was one of those eager to take advantage of the new opportunities to study. Copernicus was convinced that the complex plan of epicycles of the Ptolemaic system would become unnecessary if the earth is itself a planet moving with the others around the sun. In his reading of classical works he had learned that several scholars were said to have considered the earth as in motion in specified ways.

C. The Founding of Modern Astronomy

1. The Copernican Revolution.—Nicolaus Copernicus (1473–1543) in Polish Prussia disposed of much of the complexity of the Ptolemaic system by assigning the central position to the sun. In the new system the earth, attended by the moon, became one of the planets revolving around the sun. Certain epicycles of the Ptolemaic system were still required, however, to compensate for the retention of the traditional idea that the planetary orbits were circles. Copernicus also proposed the daily axial rotation of the earth from west to east, so that the daily circling of the celestial bodies around us became simply the apparent motion of the scenery. He published the heliocentric theory in his book *De revolutionibus orbium coelestium*, which first appeared in 1543, the year Copernicus died. (*See* Copernicus, Nicolaus.)

The theory of the earth in motion was an abrupt departure from the view that with few exceptions had persisted since the beginnings of reflections about it. Religious leaders abhorred the new idea as a doctrine that seemed to demote man from his central position in the universe to a place of lesser importance. Some scholars opposed the new idea because it was not then supported by convincing proof; its greater simplicity in accounting for the observed celestial motions was the only argument offered in its defense. Indeed, the theory seemed to be disputed by the evidence of the celestial bodies themselves, as Tycho presently discovered.

Tycho Brahe (1546–1601), a native of the extreme south of Sweden, then a part of Denmark, was the first noted astronomical observer of modern times. He spent the most productive years of his life, from 1576 to 1597, at the fine observatory the king of Denmark had helped to finance for him on the island of Hven, 20 mi. N.E. of Copenhagen. Because this period preceded the invention of the telescope, Tycho's instruments had only plain sights instead of lenses; but they had metal circles that were larger and more accurately divided than ever before, and the observed positions of the celestial bodies were corrected for the first time for effects of atmospheric refraction. These improvements, together with allowances for the errors inherent in his instruments, made it possible for Tycho and his associates to measure the places of stars and planets in the heavens with the remarkably small average error for naked-eye observations of scarcely more than a minute of arc.

Tycho and other observers of his time had the mistaken idea that the brightest, and presumably the nearest, stars showed appreciable disks, having diameters about $\frac{1}{30}$ of the sun's apparent diameter. If the stars were actually as large as the sun, their distances from us would then be only about 30 times the sun's distance. At such small distances these stars should show conspicuous annual parallax oscillations if the earth revolves around the sun. Observing the directions of some of the brightest stars through the year, Tycho was unable to detect any oscillations at all. Either the stars were thousands of times more remote than the sun's distance, which seemed impossibly great at the time, or else the Copernican theory of the earth's revolution was untrue. Tycho proposed as a compromise that the sun revolved around a stationary earth, while all the other planets went around the sun. Late in his life, Tycho moved from Hven to Prague, taking his instruments and records with him. There he obtained the assistance of Kepler, who was as skilled in calculation as Tycho was in precise observation. (*See* Brahe, Tycho.)

Johannes Kepler (1571–1630) inherited Tycho's records of observed positions of planets over many years. He began with Mars and devised a simple way of transforming its directions seen from the earth to corresponding places in its orbit around the sun. After much experimenting with traditional epicycles to represent the orbit, he concluded that the planet's path was simply an ellipse. As applied at first only to Mars, Kepler announced in his *Astronomia nova* of 1609 the first two of his three laws of planetary motions: (1) The orbit of each planet is an ellipse with the sun at one of its focuses; (2) Each planet revolves so that a line joining it with the sun sweeps over equal areas in equal intervals of time. The remaining law was given in his *De harmonice mundi* of 1619; (3) The squares of the periods of revolution of any two planets are in the same proportion as the cubes of their mean distances from the sun. The first and second laws assert that the planets revolve in ellipses, not circles, and therefore at nonuniform rates around the sun. The third, or "harmonic," law gives a useful proportion from which to calculate very nearly the mean distances of the other planets from the sun when the distance of one planet is known. The known distance is usually considered that of the earth, and this distance is accordingly called the astronomical unit. (*See* Kepler, Johannes.)

While Kepler was engaged in his studies of planetary motions, his contemporary, Galileo Galilei (1564–1642) in Italy, heard a rumour that a spectaclemaker in Holland had combined lenses in such a way as to make a distant object look nearer and clearer. Galileo fitted two lenses into a tube and went out, in 1609, to view the heavens. The stars appeared no larger through this "optic tube," but fainter ones could be seen. He also saw the mysterious Milky Way as a "mass of innumerable stars." Some of the nearer celestial objects appeared larger as well as clearer; Galileo observed mountains on the moon, phases of Venus like those of the moon, and the four bright satellites of Jupiter. Later he saw dark sunspots carried across the disk of the sun by its rotation. The earliest discoveries were first reported in his small *Sidereus nuncius* (1610). Other European observers, notably David Fabricius, Simon Marius and Christoph Scheiner, had small telescopes at about the same time and participated in some of these discoveries, but did not dramatize them as effectively. Much

that Galileo saw in the heavens with the telescope seemed in harmony with the Copernican theory of the revolving and rotating earth, a theory he ably defended in his great *Dialogue of the Two Chief Systems of the World* (1632).

Galileo was an experimental scientist whose conclusions were based on observation rather than on the traditional fitness of things. His predecessors had supposed with Aristotle that rest was the natural state and motion an enforced one; the continued motion of a body had required an explanation of how it was kept in motion. Galileo's experiments with falling bodies led to the radically different law of inertia: A body under no constraint continues to move uniformly in a straight line or else to remain at rest. Only change of motion, either in speed or direction, or both, now required explanation. This was the beginning on which Newton would formulate the laws of motion of bodies on the earth and in the heavens. (*See* GALILEO GALILEI.)

2. Dynamical Astronomy.—Isaac Newton (1642–1727) was born in England in the year of Galileo's death. His persistent curiosity concerning a variety of perplexing matters in physical science was matched by his remarkable ability to supply the reasons for them. At the age of 24 he set out to interpret motions in the universe as controlled by a single force. From the early Greek scholars to Kepler, these motions had been represented only by geometrical means without interpretation. The principle of inertia, grasped in greater or lesser degree by Galileo, René Descartes and Robert Hooke, received its classic formulation in the second of the three laws of motion which Newton prefixed to his *Philosophiae naturalis principia mathematica* (1687). These laws were based on the concept of force. The amount of the force exerted on a body is directly proportional to the mass of that body multiplied by its acceleration, or rate of change of velocity. Because velocity is speed in a specified direction, acceleration may appear as changing speed or changing direction, or both. A falling stone picks up speed as it falls. A planet revolving around the sun is continuously accelerated; its fall keeps changing the direction in which it revolves. In both cases a force is operating. This is the substance of Newton's second law of motion. The first law is the obvious corollary that if no force is exerted there is no acceleration; and the third law is concerned with the equality of action and reaction.

Newton sought to interpret the motions of the planets, as described by Kepler's laws, on the basis of the three laws of motion. Given an initial motion in a particular direction, an otherwise undisturbed planet would go on moving uniformly in a straight line forever. The planet is continuously attracted by the sun, however, and keeps departing from a straight line course in the sun's direction. Thus a planet revolves. Newton showed that the force of the sun's attraction is proportional directly to the product of the masses of the sun and planet, and inversely as the square of the distance between them. Next, on comparing the acceleration toward the earth of a stone near the earth's surface with that of the moon approximately 60 times as far away, he found a similar rule for the force of the earth's attraction. Newton then concluded that he had discovered the law that applies to the attractive force exerted by any body anywhere, and so announced it as the law of universal gravitation: Every particle of matter in the universe attracts every other particle with a force that is proportional directly to the product of their masses, and inversely as the square of the distance between them. (*See* NEWTON, SIR ISAAC.)

The law of gravitation made it possible to represent and predict the motion of a planet relative to the sun as though the planet were influenced only by the sun's attraction. This problem of two bodies could now be solved directly and completely. The resulting elliptical orbit could serve as a first approximation, because the sun has the dominant mass in the solar system and also because each planet is widely separated from any of the others. The planet considered, however, is subject to the perturbations, that is, the departures, from the two-body orbit caused by the attractions of all the other members of the sun's family. Thus the problem to be solved for a more precise representation of the planet's motion is that of many bodies. Progress in this complex problem in England through the 18th century was retarded by the retention of the less explicit notations that Newton had preferred to employ. This important work passed into the hands of a succession of able continental mathematicians, who developed and applied the more powerful operations of the calculus. Especially noteworthy among these mathematicians were L. Euler (1707–83), A. C. Clairaut (1713–65), J. D'Alembert (1717–83), J. L. Lagrange (1736–1813) and P. S. Laplace (1749–1827). Laplace summed up the achievements of his predecessors and himself in his great *Mécanique céleste* (5 vol., 1799–1825).

Among the more prominent results of the work of these investigators in dynamical astronomy, Euler in 1753 applied the method of the variation of parameters in the treatment of perturbations; the orbit of a body remains an ellipse having its elements, such as the size and eccentricity of the ellipse, continuously changing under the disturbing forces. D'Alembert, in 1749, established the earth's precession on a sound basis of theory. Lagrange introduced methods of great generality into mechanics. He and Laplace investigated the limits within which the elements of the planetary elliptic orbits must lie, and they demonstrated the very long life expectancy of the solar system. C. F. Gauss (1777–1855) published in his *Theoria motus* (1809) the method of least squares, by which the most probable value of a result can be inferred from observational data. He also described a mode of calculating the orbit of a planet from three observed positions in the heavens and afterward employed it to recover the first discovered asteroid, Ceres, which had seemed likely to be lost. The complex theory of the moon's motion, the work of many investigators, was given its present form by E. W. Brown (1866–1938).

3. Development of the Telescope.—The earliest form of the telescope, having a convex object glass and a concave eyepiece, gave an erect image but a small field even with low powers. This Galilean telescope was soon replaced for astronomical purposes by one in which both lenses were convex; this gave an inverted image but a larger field. In either form, however, the single lens of the object glass did not give a clear image of the object examined. The difficulty was mainly chromatic aberration; a single lens disperses the light, bringing its component colours to focus at different distances from the lens. A partial remedy was effected by greatly increasing the length of the instrument. Telescopes of the 17th century became so excessively long, sometimes much more than 100 ft., that the problem of supporting and controlling them was serious; the two lenses were either contained in long wooden tubes or else were supported separately. With such unwieldy apparatus, however, Christiaan Huygens (1629–95) in Holland discovered Saturn's brightest satellite, and in 1659 concluded that the planet is encircled by a thin ring; and G. D. Cassini (1625–1712) at Paris, in addition to making other noteworthy observations of planets, saw in 1675 the division in Saturn's rings that bears his name.

Newton's opinion that the colour dispersion of a lens was independent of the kind of glass of which it was made discouraged for half a century attempts to compensate the chromatic difficulty with a second lens of different composition. The opinion did inspire Newton, however, to construct, in 1668, a model of a telescope that is free from chromatic aberration; it was a reflecting telescope having a concave mirror as its objective. At about the same time, J. Gregory and N. Cassegrain suggested somewhat different designs of the new telescope. Increase in size and improvement in performance of early reflecting telescopes is peculiarly associated with the name of William Herschel (1738–1822) in England; he constructed many mirrors of various diameters, culminating in the 48-in. mirror of a telescope 40 ft. long. Herschel's many achievements with his telescopes, especially with some of more moderate dimensions, included the discovery of the Planet Uranus. He is also known as a pioneer in sidereal astronomy. William Parsons, third earl of Rosse, in Ireland, possessed the giant among the early reflectors; its mirror was 72 in. in diameter. This telescope was first used in 1845. Among its limited triumphs was the revelation of the spiral form of the galaxy M51, a form now known to be characteristic of many

galaxies.

Meanwhile, the development of the refracting telescope was made possible by the invention of the achromatic object glass, a combination of a convex lens of crown glass and a concave lens of flint glass. First designed in 1729, the combination was improved by John Dolland in England in 1758. Joseph von Fraunhofer (1787–1826) in Germany designed and constructed some of the largest refractors of the early 19th century, including a 9½-in. instrument for the Dorpat observatory, Tartu, Estonia. Construction of refracting telescopes in the United States began in earnest around the middle of the century. Alvan Clark and Sons, near Boston, became especially famous as makers of very large lenses. They made the objectives for the 36-in. telescope of the Lick observatory, on Mt. Hamilton, Calif., completed in 1888, and the 40-in. telescope of the Yerkes observatory, Williams Bay, Wis., in 1897, still the largest of all refractors. The Yerkes telescope approaches the limiting diameter for instruments of this type, where the object glass, which is supported only around its circumference, may become heavy enough to sag under its own weight.

The shift back to the reflecting telescope toward the end of the 19th century was encouraged by the substitution of glass for the original speculum metal for the mirror. Silver coating of the glass was achieved in 1856, and coating with more effective and durable aluminum began in 1932. The reflecting telescope with the greatest diameter at mid-20th century was the 200-in. Hale telescope on Palomar mountain in California, completed in 1948. The second in size was the 120-in. telescope (1959) of the Lick observatory, and the third was the 100-in. telescope (1917) on Mt. Wilson near Pasadena, Calif. These and many other reflecting telescopes were employed primarily as cameras, and they served this purpose admirably for very limited areas of the heavens. The Schmidt reflecting telescope, designed by Bernhard Schmidt (1879–1935) at the Hamburg observatory in Germany and first described by him in 1932, was used as a high-speed astronomical camera. The largest of the numerous instruments of this and allied types was at the Palomar observatory; it has a correcting plate 48 in. in diameter and a 72-in. mirror.

Efforts to increase the power of optical telescopes by constructing larger instruments became limited by the mid-20th century owing both to physical difficulties in constructing and mounting anything larger than a 200-in. mirror and the immense costs involved. Alternatives were to make existing instruments more efficient by using improved techniques or by operating them above the obstructing effects of the earth's atmosphere. Experiments with electronic image-producers also were in progress, and photographs were taken from manned and unmanned balloons and rockets above the most troublesome levels of the atmosphere. Proposals were heard for space stations and even for an observing station on the moon. The alternative of employing receiving apparatus of new types met with significant success in the radio telescope. The radio telescope is analogous to the optical instrument, having an antenna for receiving and concentrating the radiation from the celestial source, and a receiver to record the strength of the radio signal. One type of radio telescope employed a flat array of collectors; an example was the "Mills cross" inferometer radio telescope in Sydney, Austr. A second type had a paraboloidal antenna resembling the mirror of the optical telescope. One example of the second type was the great radio telescope completed at the Jodrell Bank experiment station of the University of Manchester with a "dish" 250 ft. in diameter. (*See* TELESCOPE; TELESCOPE, RADIO.)

4. The Sun.—Astronomy of the 19th century and into the beginning of the 20th century had become to a considerable extent a description of the celestial bodies combined with extraterrestrial surveying. Physics for its part had become a bookkeeping of past achievements where the hope of progress, as a distinguished physicist remarked, seemed to be the evaluation of the next decimal place. Early in the present century came such novelties as the quantum theory (1900) of Max Planck and inquiries about the structure of the atom. Astronomers began in earnest to employ apparatus and techniques in the study of the heavens similar to those of the terrestrial physical laboratory. The new astronomy, or astrophysics, initiated exciting inquiries in which physicists collaborated with profit to both.

The cause of the dark lines in the solar spectrum, first observed by J. von Fraunhofer, in 1814, remained unknown until 1859, when G. R. Kirchhoff (1824–87) announced the basic laws of spectroscopy. These laws showed that the dark lines are abstracted from the sunlight by gases above the sun's surface at characteristic wave lengths which reveal the chemical composition of the gases. In the following year, dark bands in the spectrum were explained as abstracted by molecules in the earth's atmosphere. With the effective use of the spectroscope, former fantastic ideas about the sun gave way to the findings of the new solar physics; the sun came to be regarded as composed of hot gas throughout. At the total solar eclipse of 1868 the chromosphere, prominences and corona were definitely shown to belong to the sun and not to the eclipsing moon; and P. J. C. Janssen (1824–1907) had thought of a way to observe the prominences with the spectroscope at times other than during an eclipse. The American astronomer C. A. Young (1834–1908) observed the bright-line "flash spectrum" of the chromosphere at an eclipse of 1869, and at the same eclipse the English astronomer J. N. Lockyer (1836–1920) found in the spectrum of a prominence a yellow line of a hitherto unrecognized element, which he called helium. The tables and atlas of the solar spectrum, published by the physicist H. A. Rowland (1848–1901), have served as the basis for subsequent investigations. With its revisions and extensions into the ultraviolet and infrared, it lists the wave lengths and intensities of 26,000 lines. More than 60 chemical elements are recognized in the sun, and 18 chemical compounds are identified, mainly in the cooler regions of sunspots.

The invention of the spectroheliograph by G. E. Hale (1868–1938) in the U.S., in 1891, and of a similar device by H. Deslandres (1853–1948) in France permitted photography of the sun in the light of a single element and at different levels above the surface. Hale later devised the spectrohelioscope to promote continuous monochromatic surveys of the sun. This instrument improved the chances of observing sudden changes such as the outbursts of solar flares. The flares, which had been reported sporadically since 1859, are likely to break out in the vicinities of large sunspot groups; they are sources of intense ultraviolet radiations, high-speed particles and bursts of emission at radio wave lengths. The spectroheliograph has much value in studies of the chromosphere and prominences. Its use with motion-picture films, initiated at the McMath-Hulbert observatory, Lake Angelus, Mich., by R. R. McMath, greatly improved the understanding of the prominences and their motions.

The discovery that sunspots vary in frequency in cycles of about ten years was announced in 1843 by an amateur German astronomer, H. S. Schwabe (1789–1875), after he had made systematic counts of the spots for 17 years. Correlation with the frequency of geomagnetic storms was soon established. R. Wolf (1816–93) and his successors at Zürich determined the overall average interval between spot maxima as 11.1 years, but in the first half of the 20th century it was more nearly 10 years. R. C. Carrington (1826–75) in England discovered in 1859 that the period of the sun's rotation increases with distance from its equator and that the zones of sunspot activity shift from higher latitudes toward the equator in the course of each sunspot number cycle, an effect observed soon afterward by G. F. W. Spörer (1822–95) and usually connected with his name. W. S. Adams, at Mount Wilson in 1906, extended the spectroscopic determination of the sun's rotation to high latitudes and found that it increases from 25 days at the equator to 33 days in latitude 75°. Hale, in 1908, observed the splitting of lines, known as the Zeeman effect, in the spectra of sunspots, showing that the spots have a strong magnetic field. In bipolar spots the leader and follower spots were found to have opposite magnetic polarities, and the signs for the southern hemisphere were opposite to those in the northern hemisphere. These relations continued until the sunspot minimum of 1913. When spots of the following cycle then began to appear in the higher latitudes, the polarity relations were completely reversed; and

the reversal has continued with each new cycle since that time. An effective scanning process, employed by H. W. and H. D. Babcock at the Hale solar laboratory in Pasadena, Calif., since 1952 for mapping magnetic fields over the sun, has revealed persistent general magnetic fields of 1 or 2 gauss of opposite polarity around the two solar poles.

Systematic photography of the sun's corona at total solar eclipses began with an eclipse of 1869. The form of the corona was soon found to be quite different at sunspot maximum and minimum. Photography of the corona and its spectrum at times other than during an eclipse began in 1930 with B. Lyot's use of the coronagraph at the Pic du Midi observatory, Hautes-Pyrénées, France. A dozen or more similar instruments have since begun operation at mountain stations in various parts of the world. Special monochromatic filters have also proved effective for viewing and photographing the corona and the prominences as well. Since the green line in the spectrum of the corona was first observed at the eclipse of 1869, 27 bright lines have been photographed. These lines were identified in 1941 by B. Edlén in Sweden. They are unusual lines of from 9 to 15 times ionized atoms of iron, nickel, calcium and argon; their degrees of ionization and their considerable widths indicate for the corona a kinetic temperature of 1,000,000° C. (*See* SUN; CORONA.)

5. The Solar System.—The five bright planets, Mercury, Venus, Mars, Jupiter and Saturn, have been recognized from very early times. The earth was formally added as the sixth by Copernicus in 1543. Uranus was discovered in 1781 and Neptune in 1846. The discovery of Pluto in 1930 completed the list of the nine known principal planets. Ceres, the first of the multitude of minor planets to be recognized, was found in 1801. The moon was the only satellite that could be observed prior to the invention of the telescope.

Some modern contributions to knowledge of the planets and their satellites are the following.

The globular form of the earth, proved by early Greek scholars, was first revealed clearly in photographs from rockets; an example was a photograph from a height of 101 mi. from a V-2 rocket launched in 1947 from White Sands, N.M. The dimensions of the oblate earth, reduced to sea level, were standardized in the international spheroid (1909) calculated by the U.S. coast and geodetic survey. New information about the earth and its atmosphere was obtained by means of artificial earth-satellites; the first of these were launched in 1957–58.

The earth's daily rotation was first demonstrated to the public by J. B. L. Foucault at Paris (1851) by the behaviour of the Foucault pendulum. It was later shown that the speed of the rotation is decreasing slowly, with accompanying periodic and irregular variations, and that the poles of the rotation axis wander over very small areas of the surface. The earth's annual revolution around the sun was first demonstrated by J. Bradley's discovery of the aberration of starlight in 1727. The solar parallax, which determines the earth's mean distance from the sun, has been derived mainly from the observations of planets nearer us than the sun's distance. Noteworthy contributions were the parallax deduced by D. Gill at the Cape of Good Hope, in 1895, from a program for several minor planets and the parallax calculated by E. Rabe in the U.S., in 1950, from the motion of the minor planet Eros. By international agreement the most probable value of the solar parallax is 8.803 seconds, and the earth's mean distance from the sun is accordingly 92,900,000 mi.

The mapping of the moon's visible face began with Galileo in 1610. Noteworthy among the selenographers of the 19th century were W. Beer and J. H. Mädler at Berlin (1837) and J. F. J. Schmidt at Athens (1878). A map by H. P. Wilkins in England (1955) shows at least 90,000 formations. An early photographic atlas was prepared by M. Loewy and P. Puiseux at Paris (1896–98). Two causes assigned to the origin of the lunar formations were meteoritic impact, advocated by R. A. Proctor in 1873, and vulcanism, by J. Nasmyth in 1874.

The rotation period of Mercury long remained in doubt because of the faintness of the surface markings. It was first determined by G. V. Schiaparelli (1835–1910) at Milan as 88 days, equal to the period of revolution, but radar studies in 1965 indicated it to be 58.6 days. The rotation period of Venus was found by the same method to be 247 (±5) days. W. S. Adams and T. Dunham at Mount Wilson concluded that water vapour and free oxygen are very scarce in the atmosphere of the planet, but that carbon dioxide is surprisingly abundant. G. P. Kuiper concluded more recently that the clouds which obscure the planet's surface may consist of carbon suboxide formed by action of the sun's ultraviolet radiation on the carbon dioxide. The U.S. spacecraft Mariner 2 passed Venus at about 21,600 mi. in 1962 and indicated a surface temperature of about 700° K.

The status of the surface markings of Mars was clarified by photographic and spectroscopic inquiries in the first half of the 20th century. The white polar caps were identified by Kuiper as rather thin deposits of ice crystals. The red areas are deserts, their colour resembling that of pulverized limonite, according to A. Dollfus. The green blotches may be coloured by something like lichens growing in the lava basins, or they may have a different cause. A network of fine markings, reported in 1877 by Schiaparelli and called by him *canali*, was interpreted by P. Lowell (1855–1916) as artificial waterways. A number of other observers, however, have not succeeded in detecting the canals. The two small satellites of Mars were discovered in 1877 by A. Hall with the then-new 26-in. refracting telescope of the U.S. Naval observatory, Washington, D.C. The inner satellite, Phobos, proved to be unique among the satellites of the solar system in having a period of revolution shorter than the planet's rotation period. The U.S. spacecraft Mariner 4 passed Mars at 6,118 mi. in 1965 and transmitted 21 photographs covering about 1% of the Martian surface. The pictures revealed an arid, crater-pocked surface.

Ceres, the first known of the minor planets, or asteroids, was discovered incidentally by G. Piazzi (1746–1826) at Palermo, Italy, in 1801; it is the largest of all, having a diameter of 480 mi. Ceres proved to have the same distance from the sun as a planet for which astronomers were then searching to fill a vacancy in a series of planetary distances known as Bode's law. Minor planets having reliably determined orbits exceeded 1,600 by the middle of the 20th century. Although they revolve mainly in orbits of rather small eccentricity between the orbits of Mars and Jupiter, a number have orbits of considerable eccentricity, and some of these come near the earth. Eros, discovered in 1898, may come within 14,000,000 mi. of the earth, and some minor planets discovered more recently make closer approaches. The minor planet Icarus, which left its trail on a Palomar photograph of 1949, passes within the orbit of Mercury; another asteroid, Hidalgo, retreats from the sun as far as the distance of Saturn. The majority vary in brightness in periods of a few hours, which are the rotation periods of these irregularly shaped bodies. According to one 20th-century theory, the smaller minor planets are fragments produced by collisions, and some of the larger ones were nicked by the collisions. The collisions have also caused the erratic orbits of these bodies, some of which fall onto the earth as meteorites.

Until well into the 20th century the giant planets, Jupiter, Saturn, Uranus and Neptune, were believed to be gaseous throughout, and Jupiter in particular was described as a sort of smaller replica of the sun. Later, however, measures of the temperature showed that these planets are about as cold as solar heating can allow them to get and that the high compression must make the interiors solid. Theoretical models of Jupiter by R. Wildt and W. C. DeMarcus in 1958 assigned a preponderant mass of hydrogen to the planet with helium second, as with the sun. Of the 12 known satellites of Jupiter, the four bright ones were discovered by Galileo in 1610, and the fifth and innermost satellite was detected by E. E. Barnard (1857–1923) in 1892. The other satellites, faint and much more distant from the planet, were found in the 20th century. Three of these were discovered by S. B. Nicholson, who showed that the orbits of the outermost satellites change rapidly because of strong perturbations by the sun.

Saturn's rings, regarded as solid by Laplace, were shown mathematically by J. Clerk Maxwell in 1857 to be composed of a multitude of small bodies, and their discrete character was confirmed spectroscopically by J. E. Keeler in 1895. Kuiper concluded that

the small bodies are either snow-covered or else composed mainly of ice; he reported from his inspection of Saturn with the Hale telescope that the only real break in the ring system is the division discovered by G. D. Cassini in 1675. Saturn's nine known satellites were all discovered prior to the 20th century. The largest and brightest satellite, Titan, has an atmosphere; its orange hue is probably caused by atmospheric action on the surface material, according to Kuiper, as seems to be true of the deserts of Mars.

Uranus, the first principal planet to be discovered in historic times, was found by W. Herschel in 1781. One of its five satellites, Miranda, was first detected by Kuiper, in 1948. Neptune was first seen at the Berlin observatory in 1846, near the place predicted for it by U. J. Leverrier in France from his calculations based on its disturbances of the motion of Uranus. J. C. Adams' contemporaneous prediction in England did not receive equally effective telescopic co-operation. Neptune's faint second satellite, Nereid, discovered by Kuiper in 1949, proved to have the most eccentric orbit, 0.75, of any known satellite.

Pluto, the most distant planet, was found in 1930 by C. W. Tombaugh in his photographs at Lowell observatory, Flagstaff, Ariz., where a search for such a planet had long been in progress. Its small size is in striking contrast to the giant statures of the other outer planets, and its orbit has the greatest eccentricity and inclination to the ecliptic of any principal planet. Kuiper has considered it definitely established that Pluto was originally a satellite of Neptune.

Comets were described by Newton as celestial bodies subject to the control of gravitation. Edmund Halley (1656–1742) in 1705 had calculated parabolic orbits of 24 comets from recorded positions in the sky. He noticed a similarity between the orbits of the great comet of 1682 and of two previous comets, decided that all three were of the same comet traveling in an elliptic orbit around the sun in a period of about 76 years and predicted the comet's return to view in 1758. This, the first recognized periodic comet, came to be known as Halley's comet. Encke's comet, discovered in 1786, was shown by the German astronomer J. F. Encke at its return in 1818 to be moving in an elliptical orbit with a period of 3.3 years; it was the second periodic comet to be established and the first of Jupiter's family of comets to be recognized. S. Arrhenius, in 1900, explained that the tails of comets are directed away from the sun because their material is repelled by the pressure of the sun's radiation, a reason that Kepler had suggested in his *Treatise on Comets* (1619). An important contribution on comets was proposed by F. L. Whipple in 1950. According to his theory, a comet far from the sun is a porous structure of ices a mile or so in diameter, in which small metallic and rocky particles are imbedded; the ices are mainly frozen methane, ammonia and water. Whenever a comet approaches the sun, some of the ices thaw. Gases issue explosively from the nucleus to form the coma and are then driven out through the tail. The solid particles released in the thaw are scattered along the comet's orbit as a meteor stream. (*See* COMET.)

E. F. F. Chladni, a German, in 1794 gave his opinion that "shooting stars" are produced when small celestial objects fall into our atmosphere and are heated by friction to incandescence. Falls of groups of stones at L'Aigle, France, in 1803 and later at Weston, Conn., were reliably reported. Yet the idea that stones fall from the sky was generally discredited until well into the 19th century. The spectacular shower of Leonid meteors in 1833 and its repetition in 1866, which had been predicted by H. A. Newton (1830–96) two years earlier, aroused much interest in meteors. Schiaparelli announced in 1866 that the stream of Perseid meteors has the same orbit around the sun as that of comet 1862 III, and in the following year the identity of the orbits of the Leonids and of comet 1866 I was established. Since then the search for parent comets of meteor streams has been rewarded in more than a dozen cases. Beginning in 1947, radar was used for observing meteor trails and measuring the speeds of the bodies. Records by D. W. R. McKinley and others at Ottawa of more than 10,000 meteors showed no speeds high enough to definitely suggest that any of these meteors came from outside the solar system. Similar results were obtained at the Jodrell Bank experiment station in Cheshire, Eng., where daytime meteor showers have also been recorded. Meanwhile, the Harvard meteor program of F. L. Whipple and associates began to employ stereoscopic photographs of meteor trails, from which the orbits of streams and their identities with orbits of parent comets were determined. Specimens from 1,600 falls of meteorites have been recovered, and 55 of these objects weigh more than a ton. More than a dozen craters or groups of craters in various parts of the world have been recognized as the work of meteorites. A meteorite large enough to have caused earth tremors to be recorded throughout the world fell in Siberia in 1908. Another example is the well-known Meteor crater in Arizona. (*See* METEOR; METEORITES.)

The first noteworthy hypothesis of the origin of the planetary system was published by Laplace in *Exposition du système du monde* (1796). His account began with a flattened nebular envelope revolving around the sun. As the nebula contracted, it abandoned successive gaseous rings that condensed into planets and their satellites. Widely acclaimed during the 19th century, this hypothesis eventually gave way to others designed to explain features of the system discovered in the meantime. An example is the protoplanet hypothesis of Kuiper. (*See* COSMOGONY.)

6. Stars and Nebulae.—The problem of measuring the very small annual parallaxes of stars and their distances therefrom was first solved by visual means in 1837–39 by F. G. W. von Struve for Vega, F. W. Bessel for 61 Cygni and T. Henderson for Alpha Centauri. Photographic methods of high precision were devised by F. Schlesinger in 1903. Because the amount of the parallax diminishes with increasing distance, reliable direct parallaxes are restricted to stars within something like 300 light-years from the sun.

Other basic data of observation are the apparent brightness of stars. In Ptolemy's early catalogue the lucid stars were divided in order of brightness into six classes, or magnitudes. This plan was adapted to modern purposes by N. Pogson, in 1856. The apparent magnitudes of standard stars at a variety of wave lengths and determined most accurately by photoelectric measures are available to investigators. The absolute magnitudes of stars, or the apparent magnitude at the distance of 10 parsecs (32.6 light-years), can be calculated when the observed magnitudes and distances are known. Where the absolute magnitudes are known independently and the apparent magnitudes have been observed, the distances can be calculated; this is the photometric means of extending the known distances of stars beyond the limit for the direct parallaxes.

A third category of basic observational data is concerned with the spectra of stars. J. von Fraunhofer, in 1823, was the first to observe dark lines in stellar spectra. E. C. Pickering (1846–1919) and associates at Harvard observatory, Harvard, Mass., began in 1885 the photographic program that resulted in the *Henry Draper Catalogue,* which with its extensions lists the positions, magnitudes and spectra of 400,000 stars. The spectra are described by means of spectral classes, mainly the work of Annie J. Cannon (1863–1941); the principal classes are lettered O, B, A, F, G, K, and M in order of decreasing surface temperatures or increasing redness of the stars.

A diagram in which the spectral classes of stars are arrayed with respect to their absolute magnitudes was constructed by H. N. Russell at Princeton observatory, Princeton, N.J., in 1913. It is often known as the Hertzsprung-Russell, or H-R, diagram, because the Danish astronomer E. Hertzsprung in 1905 had recognized that some red stars are much brighter intrinsically than others and had called the two groups giant stars and dwarf stars respectively. In Russell's diagram the majority of the plotted points form a band that extends from the very luminous B-type stars to the M-type dwarfs; this is known as the main sequence. The giant stars lie above this sequence in the diagram and the supergiants far above it. White dwarf stars were later discovered and added below the main sequence. The H-R diagram inspired and guided subsequent researches on the stars. In appropriate cases, as for star clusters, the H-R diagram is replaced by the colour-magnitude diagram because the colour indexes of stars can be determined more readily and more precisely than the spectral

classes.

A fourth category of basic data comprises the masses of stars; these can be calculated for binary stars where their period of revolution and size of orbit are known. Castor, the first of the very numerous visual binaries, was found to be revolving by W. Herschel in 1803. The binary character of Mizar, the first-known spectroscopic double, was discovered by Harvard astronomers in 1889 from the doubling of its spectral lines. The periodic decline in the brightness of Algol, the first-known eclipsing binary, was correctly explained by J. Goodricke (1764–86). The masses of single stars may also be derived, with certain exceptions, from the mass-luminosity relation discovered in 1924 by A. S. Eddington (1882–1944).

The distances of celestial objects more remote than the limit for reliable direct parallaxes are found by photometric means when these objects are, or are associated with, recognized distance indicators. Cepheid variable stars are such indicators; they are yellow supergiant pulsating stars that can be observed even as far away as the nearer exterior galaxies. H. S. Leavitt at Harvard reported in 1912 that the period in which their brightness varies increases as the observed median magnitude of the star is brighter. H. Shapley, in 1913, established the corresponding standard period-luminosity relation applicable to Cepheids anywhere. W. Baade's announcement in 1952 that the absolute magnitudes of classical Cepheids are all 1.5 magnitudes brighter than previously supposed resulted in the doubling of all celestial distances previously determined by means of Cepheids. More recently, H. C. Arp showed that the period-luminosity relation of the Cepheids may be a band rather than a line. Another type of pulsating variable stars, the RR Lyrae variables, have also been useful as distance indicators because all their median luminosities are believed to be the same; but these stars are intrinsically less bright than the Cepheids and cannot be seen as far away.

Star clusters and nebulae began to be discovered in large numbers by the Herschels and to be listed in catalogs of increasing extent. Dreyer's *New General Catalogue* (1888) and its extensions in 1895 and 1908 included over 13,000 such objects. Because the members of a star cluster are all practically at the same distance from the earth, they may be compared fairly one with another. The clusters accordingly have added to the understanding of the relations between the different kinds of stars and of their places in the evolution of stars. The colour-magnitude diagrams of clusters differ in a remarkable way that suggests differences in the age of the clusters. Very young clusters have the main sequence practically intact. With increasing age of the clusters the stars break away from the main sequence at lower and lower points, as shown by H. L. Johnson and Allan Sandage in 1954, and move into the giant sequences. For the oldest clusters and the globular clusters, which are believed to be as old as the galaxy itself, the remaining main sequence begins with stars nearly as yellow as the sun and goes on into the red stars. Sandage's semiempirical evolution tracks of stars in the globular cluster M3 leave the main sequence at spectral type F5, extend up and to the right, and finally go back to the left to the region of the blue stars. (*See* STAR.)

Stationary hazy spots among the stars were all known as nebulae in former times. The "great nebula" in Andromeda had been recognized before the invention of the telescope. Huygens thought he had discovered the Orion nebula in 1656, but it had been seen before. Halley worked on the nebulae as early as the second decade of the 18th century. Although the idea had developed that all nebulae were really star clusters, W. Huggins' observation in 1864 of bright lines in the spectrum of a planetary nebula in Draco showed that some of these objects must be gaseous. Eventually a numerous class of spiral and associated nebulae, which seemed to avoid the Milky Way, were given the name "extragalactic nebulae" to distinguish them from the nebulae proper, which congregate toward this band of the heavens; the former proved later to be exterior galaxies. E. P. Hubble (1889–1953), in 1922, showed that nebulae are made luminous by involved or neighbouring stars. Where the stars are cooler than spectral type B1, the nebulae shine mainly by reflected starlight; where the stars are very hot, they ionize the gases of the nebulae and set them glowing. Prominent bright lines in the spectra of emission nebulae were explained by I. S. Bowen in 1927 as "forbidden lines" of oxygen and nitrogen. In the absence of neighbouring stars the nebulae are practically dark. M. Wolf (1863–1932) and E. E. Barnard had previously shown that the dark rifts in the Milky Way are areas of dark nebulae and not vacancies. In 1904, J. Hartmann observed "stationary lines" in the spectrum of the binary star Delta Orionis; and eventually these and similar lines in the spectra of other stars were understood to be interstellar lines caused by absorption of the starlight by intervening cosmic gases. R. J. Trumpler's studies of galactic clusters showed in 1930 that starlight is also dimmed and reddened by interstellar dust, which is widespread in the heavens and relatively concentrated in the vicinity of the Milky Way. (*See* NEBULA.)

The idea, pioneered by Kant and Laplace in the 18th century that stars condense from nebulae has persisted. Contraction was believed in the early theories to be the sole process that kept the stars shining thereafter; but it proved insufficient to account for the long lives of many stars. Interest in the problem of stellar evolution reawakened in the 1920s with the work of J. Jeans and A. S. Eddington, the latter suggesting subatomic means for the generation of stellar energy, while in 1938 H. A. Bethe proposed the fusion of lighter into heavier chemical elements in the interiors of stars as an important supplement to contraction; and a new evolution theory presently appeared. After condensing from a cosmic cloud, according to the theory, a group of stars goes on contracting and moves to the left in the colour-magnitude diagram until the stars are arrayed in order of mass along the main sequence. Contraction is then replaced by fusion of hydrogen into helium in the cores of the stars. The stars grow hotter and begin to expand, leaving the main sequence to become giant stars. When the available fuel is exhausted, the stars contract again until they become white dwarfs. Hydrogen fusion is the main process and may be the only one of importance in stars like the sun. More massive stars may continue to build up heavier elements at least as far as iron, as W. A. Fowler and others explained in 1956; these stars may attain central temperatures of several billion (milliard) degrees and may explode as supernovae before they begin to decline.

7. The Galactic System.—The system of the Milky Way has come to be known as "our galaxy," and the term "Milky Way" is applied usually only to the luminous band around the heavens. A number of scholars in the 18th century believed the system of stars around us to have a much-flattened structure. W. Herschel reached the same conclusion in 1784 from his star "gauges," but he decided later that the depth of the system in space was unfathomable. The statistical treatment of star counts remained about the only means of trying to determine the galactic structure until well into the 20th century, and it made little progress. Shapley's measures of the distances of globular star clusters, basically by means of their RR Lyrae variable stars, led to his conclusion, in 1917, that the galaxy has finite extent and that the sun is far from its centre. The original dimensions that he gave were considerably too large and could not be corrected until Trumpler's work, in 1930, on the effect of the cosmic dust in magnifying the photometric distances of stars. The diameter of the disk of the galaxy is usually given as 80,000 light-years and the distance of the galactic centre from the sun as about 33,000 light-years in the direction of Sagittarius, where Shapley placed it.

Although the flattened disk of the galaxy, as evidenced by the appearance of the Milky Way, suggested a centrifugal effect of the galactic rotation, no other effect was recognized until B. Lindblad, in Sweden in 1926, demonstrated a general rotation around a centre also in the direction of Sagittarius. J. H. Oort, in the Netherlands in 1927, reported a differential effect of the rotation from his studies of the radial velocities of stars in the sun's vicinity. Oort's studies showed that the disk rotates in a longer period as the distance from the centre increases.

The sun is moving in the rotation in the direction of Cygnus with a speed of 134 mi. per second, as determined by Dutch radio astronomers in 1954. The double-armed spiral pattern of stars gas and dust imbedded in the disk of the galaxy was first definitely

traced in the heavens, in 1951, by W. W. Morgan, S. Sharpless and D. E. Osterbrock at Yerkes observatory with the collaboration of other astronomers. They located many emission nebulae and associated blue stars in various regions of the Milky Way, objects that outlined parts of two spiral arms and the suggestion of a third arm. This important tracing of the arms was soon extended by radio astronomers. (*See* Galaxy.)

8. Radio Astronomy.—Cosmic radiations at radio wave lengths were first detected by K. G. Jansky in 1931. Grote Reber, an electronics engineer at Wheaton, Ill., employed a fixed 31-ft. paraboloidal antenna in 1936 to make recordings of radio emission from various areas of the Milky Way as they crossed his meridian. Radio reception from the sun was recorded at British radio stations in 1942, when a large sunspot group with associated solar flares was passing near the centre of the sun's disk and was first announced in 1946. J. S. Hey and associates in England, in 1946, discovered the first-known discrete cosmic radio source, in the constellation Cygnus. Also in England and in that year, A. C. B. Lovell and associates at the Jodrell Bank experiment station made extensive recordings by radar of the shower of Giacobinid meteors; and in the following year they began daytime recordings of meteor showers.

Following Reber's pioneer radio map of the sky, other such maps were made at various wave lengths of the continuous radio spectrum and with improved resolving power. As an example, a map by H. C. Ko and J. D. Kraus, in 1957, based on their observations at Ohio State university, showed the Milky Way prominently and also the positions of the brightest discrete radio sources. Only a few discrete sources had by mid-20th century been identified with optical instruments, particularly by W. Baade and R. Minkowski with the 200-in. Palomar telescope; these include an emission nebula in Cassiopeia, a pair of colliding galaxies in Cygnus, the Crab nebula and the nucleus of our galaxy. The only recognized emission line in the radio spectrum, at the wave length of 21 cm., was discovered in 1951 by Harvard physicists H. I. Ewen and E. M. Purcell; the line is produced by a slight change at the lowest energy level of the hydrogen atom and has also been observed as an absorption line. Tracings of the spiral arms of the galaxy by use of this line were accomplished especially by observers at the Leiden observatory, in the Netherlands in 1954, and at the Radiophysics laboratory, Sydney, Austr., at about the same time. Absorption lines of molecular hydrogen and the hydroxyl radical, OH, were discovered by A. H. Barrett and his colleagues at Massachusetts Institute of Technology in 1964. (*See* Radio Astronomy.)

9. The Exterior Galaxies.—Although Kant, as early as 1755, had thought that the nebulae might be "other universes," his speculation was not generally received with favour. It remained for E. P. Hubble to establish in 1924 the status of the hitherto mysterious spiral structures and other extragalactic nebulae. His photographs with the 100-in. Mt. Wilson telescope showed separate stars and among them Cepheid variable stars in some of these objects. The distances derived from the Cepheids ran into millions of light-years. These were galaxies beyond our own. Meanwhile, the scale of distances derived originally for the exterior galaxies required revision, as Hubble suspected might be the case. The distances of galaxies in which Cepheid variable stars were employed have been multiplied by the factor 2 by Baade's revision in 1952, and the distances originally assigned to more remote galaxies may need to be multiplied by a factor as great as 10, as Sandage showed in 1958.

Studies of the great spiral in Andromeda, which except for its larger dimensions resembles our spiral system quite closely, provided the pattern for interpreting features of our own galaxy. In 1943, Baade announced that the stars generally are grouped in two distinct populations. Population I comprises young stars, represented by the stars right around us in the dusty arm of our galaxy and in the arms of the Andromeda spiral. Population II comprises old stars, represented by stars of the globular clusters and those in the central regions of galaxies like ours. Because these are extreme populations, three additional types have since been proposed tentatively to include stars of intermediate ages.

From his researches on the spectra of galaxies, Hubble announced in 1929 that the spectral lines are displaced to the red in direct proportion to the distances. Here began the spectacular picture of the expanding universe. M. L. Humason later extended the inquiry to the Hydra cluster of galaxies at about the spectroscopic limit of the 200-in. telescope; he discovered that the red shifts for these galaxies correspond to a recession velocity of $\frac{1}{5}$ the speed of light.

W. A. Baum's photoelectric measures with the same telescope, in 1957, extended the limit to the most remote clusters of galaxies then definitely recognized; he found that there the red shifts of the spectral lines correspond to a velocity of recession equal to $\frac{2}{5}$ the speed of light.

The discovery by M. Schmidt in 1963 of quasi-stellar objects (*see* below) greatly extended the boundaries of the known universe; with velocities of recession equal to and exceeding $\frac{4}{5}$ of the speed of light, these objects were apparently by far the most remote from the earth. Their discovery seemed to support those who favoured the "big bang" model of the origin of the universe, as opposed to those favouring the "steady state" theory (*see* further Cosmogony). (R. H. Br.; X.)

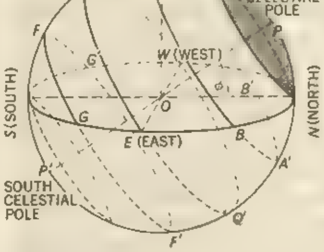
II. MODERN DESCRIPTIVE ASTRONOMY

A. The Celestial Pageant

1. The Celestial Sphere.—To an observer, ancient or modern, the night sky appears as a hemisphere resting on the horizon. Consequently, the simplest descriptions of the motions of the heavenly bodies are those presented on a sphere. Fig. 2 illustrates the daily circuits of celestial bodies.

As the earth rotates from west to east, the celestial sphere appears to rotate from east to west on its axis, PP'; in other words, the point, P, remains stationary and Polaris, the bright star which is close to the north pole, moves in a very small circle around it. All objects that lie in the shaded area remain above the horizon at all times, slowly circling the pole, although, of course, they are invisible in daytime. A star situated at some point on the circle $BAB'A'$ will move along that circle, rising at B and setting at B'. A star on the circle $EQWQ'$ will rise at the east point and set at the west point just 12 hours later; this circle is the celestial equator. Stars south of the celestial equator are above the horizon for less than 12 hours daily as seen from the northern hemisphere of the earth; this would be the case for a star on the circle $GFG'F'$. Finally, the circle $NPAS$ is known as the celestial meridian. Notice that stars reach their greatest elevation above the horizon when they pass across the meridian.

The diagram assumes the observer is located at a northern latitude which is equal to the angle ϕ on the diagram, or approximately 35°. If the observer is at a very different latitude the diagram should be redrawn. Thus, for an observer on the equator, the north celestial pole is on the horizon and all stars rise vertically from the horizon and set just 12 hours later; on the other hand, for an observer at the south pole of the earth, the south celestial pole is directly overhead in the zenith and the stars of the southern celestial hemisphere complete their daily circles always parallel to the horizon, never rising or setting.

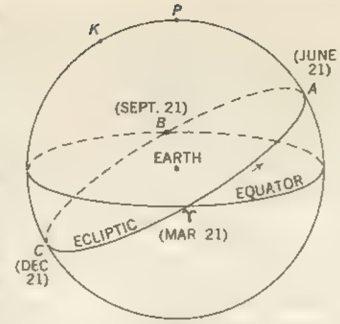


FROM CHARLES A. YOUNG, "A TEXTBOOK OF GENERAL ASTRONOMY"; BY PERMISSION OF GINN AND CO. (1898)

FIG. 2.—APPARENT DAILY MOTIONS OF CELESTIAL BODIES BECAUSE OF EARTH'S ROTATION. *O* REPRESENTS POSITION OF OBSERVER ON EARTH

2. The Seasons.—The sun, the moon and the planets move perceptibly among the stars. The moon moves approximately 13° every day in a general easterly direction. The sun moves much more slowly, progressing about 1° every day in its easterly journey. The planets move more irregularly. One feature that all of these apparent motions have in common is that the bodies travel along a rather narrow belt of the sky known as the zodiac. The central line of this belt is called

the ecliptic; it is the path the sun follows among the stars, making an angle of 23° 27′ with the celestial equator as illustrated in Figure 3. On March 21 the sun is at the intersection of the ecliptic and the equator traveling east and north; the symbol of the ram's horns (♈) traditionally used to designate this point is of ancient origin; the point is known as the vernal equinox, since, when the sun is there, the length of the day is equal to the length of the night. During the next three months the sun continues to move northeast until it reaches the summer solstice at *A*. At this point it is 23° 27′ north of the celestial equator and consequently (cf. fig. 2) nights are at their shortest on the northern hemisphere of the earth and at their longest on the southern hemisphere. From this point the sun's path turns southeast past the autumnal equinox at *B* to the winter solstice at *C*. It is because the sun's apparent path is so much inclined to the celestial equator that the seasons are so pronounced. Actually, it is the earth's annual circuit around the sun which makes the sun appear to be moving among the stars as seen from the earth. Furthermore, the fact that the earth's axis of rotation is directed 23° 27′ away from the pole of the earth's orbit around the sun accounts for the inclination of the ecliptic to the celestial equator.



FROM W. M. SMART, "TEXTBOOK ON SPHERICAL ASTRONOMY," CAMBRIDGE UNIVERSITY PRESS, PUBLISHERS (1931)

FIG. 3.—APPARENT YEARLY MOTION OF SUN AMONG THE STARS. NORTH POLE OF THE EQUATOR IS AT *P*, THE POLE OF THE ECLIPTIC AT *K*. DIRECTION OF SUN'S APPARENT MOTION IS INDICATED BY ARROW

The ancients divided the zodiac into 12 equal constellations or "signs," each sign bearing the name of the fancied pattern the stars in that portion of the sky appeared to resemble. Thus, there was Aries the ram, Taurus the bull, Gemini the twins, etc. It is a simple matter to follow the motion of the moon or of the planets along the zodiac but much more difficult in the case of the blindingly bright sun. Despite this fact, Hipparchus (fl. 146–126 B.C.) was able to establish that there is a very slow shift in the position of the ecliptic on the celestial sphere amounting to about 1° 15′ per century. Two thousand years later, in 1888, it became clear that there are irregular changes in the position of the pole of the earth; and in 1926 it was found that there are variations in the rate of the earth's rotation over a period of a decade or so. The development of much more accurate timepieces, such as the crystal clock, have immensely improved observations since 1940; as a result it has been established that there are also short-term fluctuations in the rate of the earth's rotation.

3. Time.—The astronomer sets his clock by the stars. The moment the vernal equinox crosses the meridian is zero hours and sidereal clocks are timed to follow the course of this point on the sky. Thus, at 6 hours it is setting on the west point on the horizon and at 18 hours it is rising at the east point. Now, according to the sidereal clocks, the sun reaches the meridian some four minutes later every day since it is traveling eastward among the stars; more precisely, solar clocks run 3 min. 56.56 sec. slow per day as compared with sidereal clocks.

The orbit of the earth around the sun is not quite circular, being closest to the sun on Jan. 2. The earth moves most rapidly when closest to the sun; consequently, the sun's apparent motion among the stars is most rapid on Jan. 2. Because of this and because the sun travels along the ecliptic, rather than straight eastward, apparent solar time as measured on the sundial runs 10 or 15 minutes fast in May and November as compared with mean solar time, a time based on a fictitious mean sun; similarly, apparent solar time is slow in February and July. (*See* TIME MEASUREMENT.)

4. Stellar Positions and Names.—The time shown by the sidereal clock when a particular star crosses the meridian is called the star's right ascension; this defines the star's position in the sky in the east-west direction. The declination of a star is its angular distance north or south of the celestial equator. Together, the two co-ordinates completely define the position of any star. The positions of hundreds of thousands of stars have been measured and listed in catalogues. The oldest such catalogue still existing is contained in the *Almagest* of Claudius Ptolemaus (fl. 127–151 A.D.), usually referred to as Ptolemy.

Thirty or 40 bright stars are still commonly referred to by the names given them by the Arabs, the Romans, the Greeks, etc. About 1,000 are designated by a Greek letter followed by the name of the constellation in which they appear. But most stars are known by their serial number in a catalogue. Thus, BD +24° 1382 refers to star No. 1382 in declination zone +24° of the *Bonner Durchmusterung* catalogue.

5. Eclipses and Occultations.—Two other phenomena with which the ancients were well acquainted were eclipses and occultations. If the moon crosses the line between the earth and a planet or a star, an occultation is said to occur. On the other hand, if the moon comes between the earth and the sun, it is said to eclipse the sun, either partially or totally, depending on the location of the observer on the earth and the position of the moon. Similarly, if the earth crosses between the sun and the moon, the moon is darkened by the earth's shadow and a lunar eclipse occurs. It was the spectacular eclipses and occultations that gave man his first positive evidence that the celestial bodies are not all at the same distance from us. He could deduce that the moon must be nearer to us than the sun, the planets and the stars. This marked the beginning of a new phase of astronomy. Hipparchus determined the distance to the moon by observing the size of the earth's shadow on the moon during a lunar eclipse, a method first suggested by Aristarchus of Samos (*c.* 250 B.C.). (*See* ECLIPSE.)

B. THE OBJECTS IN OUTER SPACE

1. The Solar System.—At this point it will be useful to have something in the nature of a road map, one which has been adapted from John Herschel (1792–1871). The sun, a huge self-luminous body, has a few insignificantly small, nonluminous bodies in its entourage, namely, the planets, of which the earth is one. On a drastically reduced scale the sun may be pictured as a brightly shining sphere 2 ft. in diameter. The planet Mercury on this scale will be the size of a rather large pinhead revolving around the sun in a circle of 82-ft. radius; Venus is a pea on a circle of radius 142 ft.; the earth, also a pea, at 215 ft.; Mars, a small cherry stone at 327 ft.; the minor planets (also called asteroids), fine grains of sand at distances of 500 to 600 ft.; Jupiter, a fair-sized orange on a circle of nearly 0.25 mi. radius; Saturn, a small orange at 0.4 mi.; Uranus, a walnut at more than 0.75 mi.; Neptune, also a walnut, at 1.25 mi.; and finally, Pluto, a pea revolving around the sun at a distance of 1.6 mi. On this scale the nearest star would be more than 10,000 mi. away.

Six of the planets have satellites revolving around them in the way the moon revolves around the earth. In addition, there are comets and meteoric matter. All of these bodies move in orbits under their mutual attraction in accordance with the law of gravitation, but since the sun is nearly 1,000 times more massive than all the others, it exerts a controlling influence.

It took much scientific controversy and insight to establish this picture. A theory that the earth rotated on its axis and revolved about the sun had been advanced in the 3rd century B.C., probably by Aristarchus of Samos, but failed to win acceptance. Indeed, it was not until more than 100 years after the death of Copernicus that his heliocentric theory finally triumphed over the various apparently valid objections to it. Johannes Kepler accepted the central position of the sun and based his three remarkable laws of planetary motion upon it, three laws that completely accounted for the complicated motions of all the planets. Kepler's third law sufficed to establish the relative distances of the planets from the sun in terms of the earth's distance. That distance, however, was exceedingly difficult to establish with any accuracy.

The Distance Scale.—From his observation of a lunar eclipse Hipparchus had found that the distance to the moon was 59 times the radius of the earth; this amounts to 230,000 mi., exceedingly close to the modern value of 238,860 mi. Three centuries later Ptolemy confirmed Hipparchus' value using the surveyor's method

of triangulation. Thus, assuming the stars are exceedingly far away, he used the position of the moon among the stars as observed simultaneously from two points far from one another on the earth's surface. The distance between the two points formed his base line and the angle between the two observed positions of the moon is equal to the angle subtended by this base at the moon.

The distance to the sun is much more difficult to measure. Since the stars are invisible in daytime they cannot be used as reference points; besides, the sun's heat affects measuring instruments. The first reliable value resulted from a determination of the distance of Mars in 1671–73 by the same surveyor's method which Ptolemy used for the moon's distance. This provided the yardstick for an approximate scale of the solar system. The most modern value of the mean distance from the earth to the sun is 93,000,000 mi. with a probable error of 11,000 mi. This resulted from an intensive international effort to measure the distance of the minor planet, Eros, in 1930–31 when it was relatively close to the earth. With the astronomical unit, or the distance of the sun, well determined, it is possible to compute the dimensions of the various members of the solar system.

The Sun.—The immense size of the sun can be understood when it is realized that its radius of 432,700 mi. is nearly twice the distance of the moon from the earth. Its mass, as measured by its gravitational pull on the earth, is 333,420 times the mass of the earth, or about 2×10^{27} tons (the number may be written as 2 followed by 27 zeros). Its mean density is 1.41 times the density of water, or only a little over a quarter of the earth's mean density. The sun rotates on its axis as do all principal members of the solar system. Its temperature on the surface is approximately 6,000° C. and the vast amount of energy constantly radiated from it is believed to arise from nuclear reactions deep in its interior where temperatures may be as high as 20,000,000° C. The surface is far from uniform in appearance and dark spots appear on it frequently; the diameters of these spots range from 500 to 50,000 mi. Sunspots have great influence on the earth's magnetic field and can even disrupt radio service; the number of spots varies greatly over an 11-year period. The relative abundance of chemical elements in the sun's outer layers as determined spectroscopically is remarkably similar to that in the earth's outer crust, with the important exception that hydrogen and helium are much more abundant in the sun.

The Earth-Moon System.—The earth and moon revolve around their common centre of gravity, which is 2,900 mi. from the earth's centre, the mass of the moon being $\frac{1}{81}$ times that of the earth. Since the diameter of the moon is about $\frac{1}{4}$ the earth's diameter (2,160 *v.* 7,921 mi.), it follows that the moon's mean density is less than that of the earth (3.34 *v.* 5.52 times that of water). The surface gravity on the moon is about $\frac{1}{6}$ the force of gravity on the earth's surface. A man who can throw a baseball 400 ft. here would be able, on the moon, to throw it nearly half a mile. Furthermore, the "velocity of escape" is much less on the moon. To escape from the earth's gravitational pull, a rocket must travel upward at a speed of about 24,000 miles per hour whereas on the moon it would require a speed of only 5,400 miles per hour. However, if the sun and moon are approximately in line with the direction in which the rocket is fired from the earth, their gravitational pull reduces somewhat the speed required for escape. The moon is without atmosphere and without life on its rugged mountainous surface.

The Planets.—Mercury, Venus, Mars, Jupiter and Saturn appear as bright stars to the naked eye and were known to the ancients. Uranus appears as a very faint star to the unaided eye and was discovered in 1781; Neptune, which can be seen with field glasses, was found in 1846; Pluto, discovered in 1930, is so faint that it was found only by means of long exposure photographs with a powerful telescope at Lowell Observatory.

Mercury, the smallest of the planets, is much of the time so near the sun that it is not noticed; it is never more than 28° away from the sun.

Venus is by far the brightest planet of all, so bright that it is easily visible in the daytime when far enough away from the sun; it is never more than 48° away from the sun. Through a telescope both Mercury and Venus exhibit phases similar to the phases of the moon, with the illuminated portion facing the sun. Venus, almost the earth's twin in size, density and surface gravity, has sufficient atmosphere to conceal its surface markings.

On the other hand, the surface markings of the reddish planet, Mars, and their seasonal changes can be fairly well observed because it has very little atmosphere. In 1965 excellent photographs of Mars were secured by the U.S. spacecraft, Mariner 4, which showed that its surface is covered with craters similar to those on the moon. On the evidence of these photographs it seemed doubtful that even rudimentary vegetable life exists there. Mars has two small satellites revolving rapidly around it.

Jupiter is the largest and most massive of the planets with a diameter of 89,000 mi., but its mean density is only 0.25 the earth's. The irregular belts that constitute its apparent surface markings vary in number, breadth and position from year to year.

Saturn is unique among the observed heavenly bodies, a great globe surrounded by a system of rings. The rings are composed of a vast aggregation of separate particles, each moving in its own orbit around the planet. In addition, there are nine larger satellites. Saturn's mean density is only 0.7 the density of water.

Uranus and Neptune, on the other hand, are similar to Jupiter in their mean densities but are much smaller.

Pluto, the most distant of the planets, revolves around the sun once every 248 years; its mean distance from the sun is 3,675,000,000 mi. or nearly 40 astronomical units.

Minor Planets, Comets, Meteors.—The minor planets (asteroids) within the reach of modern telescopes must number many thousands. More than 2,000 have been photographed and more than 1,600 have been sufficiently observed for their orbits to be determined. Ceres, the largest, is 480 mi. in diameter; the majority probably range from one to 50 mi. in diameter. Icarus, only 0.6 mi. in diameter, comes closer to the sun than any other known minor planet. It passes within 4,000,000 mi. (in 1968) of the earth, and might pass much closer some time in the future.

One of the most spectacular and rare of all celestial phenomena is a bright comet. Occasionally, one can be seen in daytime with a nebulous head as large as the moon accompanied by a long tail. But the great majority of comets are mere wisps of light, visible only with a telescope; a dozen or so are picked up every year but relatively few return to visibility near the sun in a thousand years. They are "airy nothings" of immense volume and very small mass. Their orbits are mostly very elongated.

Meteors are small pieces of matter seen only when, falling into the earth's atmosphere, they appear as shooting stars. There is evidence that some meteors were once associated with comets.

Underlying Implications.—Kepler's three laws of planetary motion sufficed to describe and predict the motions of all the planets with an accuracy adequate to the observations existing in the 17th century. When Isaac Newton published his law of gravitation it was realized that Kepler's laws were a consequence of Newton's more general principle. Various slight discrepancies which later appeared in the planetary motions were satisfactorily accounted for by the relativity theory of Albert Einstein (1879–1955). There is another notable feature, however, namely that the nine planets revolve around the sun in the same direction that the sun rotates. Moreover, all but Venus rotate on their axes in the same sense and, with few exceptions, the minor planets and planetary satellites also conform to the pattern, although not all of them move close to the plane of the ecliptic.

2. The Stars.—The fact that the stars are other suns at immense distances from us was exceedingly difficult to establish with certainty although Newton and others believed it probable. The first actual evidence that stars are not at an infinite distance came in 1718 when Edmund Halley discovered that a few of the brightest stars had definitely moved from their positions given in Ptolemy's catalogue. The inference that the stars are subject to the law of gravitation was suggested by the discovery of William Herschel that the two components of a double star were moving around one another. In 1838, the first successful measurement of a stellar distance was made by Friedrich Bessel (1784–1846) and others.

Distances.—Measurement of stellar distances by the method of triangulation from different sides of the earth's orbit had been attempted many times before Bessel used it. At six-month intervals the position of a comparatively close star is measured relative to a much more distant star which is apparently close to it on the celestial sphere. As seen from opposite sides of the earth's orbit, the nearby star shifts slightly with respect to the distant star. Stellar distances turned out to be so enormous that a new unit, the light-year, was devised; *i.e.*, the distance light travels in one year. Thus, one light-year is equal to 6.33×10^4 astronomical units, or 5.88×10^{12} (5,880,000,000,000) mi. Accordingly, the distance to Proxima Centauri, the nearest star, is 4.3 light-years. The triangulation method has been used in finding the distances of about 6,000 stars but is not suitable for distances greater than 100 light-years. Other methods have been developed to measure greater distances. (*See* PHOTOMETRY, CELESTIAL.)

Stellar Characteristics.—Stars are the primary bodies in which the light of the universe is generated. Spectroscopic studies have shown that stars generally have roughly the same chemical composition, with hydrogen predominating. The studies have also shown that the surface temperatures vary from approximately 1,500° C. for the very red stars to perhaps 50,000° C. for the bluest of them. Stars rotate on their axes, as does the sun, and very occasionally when the rate of rotation is very fast a star becomes unstable and splits into two parts.

Stellar masses are well known from studies of double stars; relatively few stars are known to have less than 0.1 of the mass of the sun and few have more than 20 times the solar mass. It appears that if the mass exceeds a certain value the star tends to become unstable; on the other hand, if the mass is less than a certain value the body is not self-luminous.

The total amount of energy radiated by a star is a function of the star's mass, the most massive stars radiating the most energy. The stars of faintest intrinsic brightness radiate less than $\frac{1}{100,000}$ as much visible light as the sun, whereas the brightest pour forth more than 20,000 times as much. Only a small percentage of all the stars are more than 10 times as luminous as the sun whereas a great many are less than $\frac{1}{10}$ as luminous.

Stars' densities also vary over a wide range; the densest are known as dwarfs and those with lowest densities are called giants or even supergiants. In certain dwarfs mean densities may reach 50,000 times that of water; at the other extreme, they may be as low as $\frac{1}{8,000}$ that of air in certain supergiants.

As seen from the sun, stars move in all directions and with velocities ranging up to more than 50 mi. per second. The sun itself moves among its neighbours with a speed of 12 mi. per second. The more massive stars with high surface temperatures move relatively slowly. Stars with low surface temperatures, whether giants or dwarfs, move at much greater speeds.

Variable Stars.—Not all stars shine with constant steady light. The medieval Arabs must have observed the variability of the light of the star, Algol, since the name means "blinking demon." Algol is an example of an eclipsing variable star in which one component of a double star periodically obscures the light from the other component. Most variable stars, however, are in an unstable state, periodically expanding and contracting. The periods range from 80 minutes to more than a year. Of great importance to astronomers are the Cepheid variable stars; a strong correlation exists between their luminosities and their periods of pulsation. The Cepheids are an important tool in measuring great distances since they are very massive and of high luminosity.

The most unstable of all the variables are the explosive stars known as novae. Very occasionally, an originally faint star expands so rapidly that its outer layers are completely driven off into space. Simultaneously its brightness increases perhaps 10,000 times, after which it gradually returns to its original brightness in the course of a year or so. As a result of the explosion, however, nebulous wisps occasionally are visible expanding rapidly away from the star. Even more rare in occurrence are the supernovae. Three of these have been observed since the year 1000 A.D. Apparently the entire star explodes leaving only a gaseous nebula behind. These nebulae are the source of very strong radio emission as in the so-called Crab nebula, which is all that remains of the supernova of 1054 A.D.

3. The Milky Way System.—The unearthly beauty of the Milky Way, spread irregularly across the sky on a clear moonless night, is enhanced by the realization that it is a galaxy of stars seen edge-on from a point within its bounds. The centre of the Milky Way system is hidden from our sight by clouds of obscuring matter in the constellation of Sagittarius. However, it can be perceived in infrared light to which the eye is not sensitive; it can also be located by the use of radio waves. Before either of these methods were used, however, its position had been inferred from the distribution in the sky of the compact swarms of stars known as globular clusters. The sun is in the outskirts of the system, approximately 30,000 light-years from the centre, while the overall equatorial diameter of the galaxy is perhaps 80,000 light-years. The total mass of the galaxy is estimated to be of the order of 10^{11} times the solar mass. The galaxy mass, of which less than 10% is interstellar matter, is heavily concentrated toward the centre of the system. One of the most notable features of our galaxy is its flatness; an overwhelming majority of the stars are fairly close to the equatorial plane of the galaxy as is most of the diffuse matter between the stars. However, in the case of certain types of stars, and of globular clusters, the distribution is more nearly spherical with respect to the galactic centre.

Rotation.—The entire galaxy rotates about its centre in a manner somewhat analogous to that of the solar system; thus, the outer parts lag behind the inner parts, forming great spiral arms as "seen" by radio waves. The period of rotation for stars in the vicinity of the sun is 230,000,000 years, with a probable error of 16,000,000 years. The stars that are concentrated most strongly toward the central plane, such as the very massive blue stars, move in nearly circular orbits around the galactic centre. Those that are relatively little concentrated toward the Milky Way plane, such as the RR Lyrae variables, move in a great variety of orbits, many of them very elongated. The sun, like the great majority of stars in our neighbourhood, is in an intermediate category, moving in a slightly eccentric, *i.e.*, flattened, orbit.

Stellar Populations.—The variety in the distribution and motions of different kinds of stars is connected with their time and manner of origin. The very massive blue stars, found predominantly in the spiral arms together with clouds of interstellar matter, are apparently of recent origin, being perhaps no more than 10,000,000 years old; these are exceptional, however. The sun, a yellow star of intermediate mass, is thought to be about 4,500,000,000 years old. Stars of certain other types, such as the RR Lyrae variables, are probably older still. In general, the stellar population of the globular clusters and in the region near the galactic centre consists of older stars than the population in the outlying portions, such as the neighbourhood of the sun.

Interstellar Matter.—Although the space between the stars is a far higher vacuum than anything ever achieved in laboratories it is not completely empty. There are vast aggregations of fine dust particles mixed with neutral and ionized gases, particularly hydrogen. The dust reddens and obscures the light of distant stars. The gases are frequently made luminous by the young blue stars associated with the clouds as in the Pleiades. The extremely low densities in the clouds enable astrophysicists to study the radiation of highly ionized gases in conditions never encountered on earth, a circumstance that has furthered the understanding of various atomic phenomena. The vast amounts of neutral hydrogen in the interstellar clouds emit a definite radio wave length and can be detected by radio receiving equipment.

4. The Universe of Galaxies.—That the Milky Way is a galaxy of stars was not established until the invention of the telescope, although several astronomers had previously speculated that it was probably so. In 1924, about three centuries after the invention of the telescope, photographs taken with the newly installed 100-in. telescope at Mt. Wilson established that the Andromeda nebula is actually another galaxy of stars. This brought to an end a lively debate of the preceding decade as to whether all the so-called nebulae were members of the Milky Way system. The spectroscope had revealed that certain nebulae close to the plane

of the Milky Way are luminous clouds of gas and that the spectra of a great many others are rather similar to stellar spectra. The Andromeda nebula falls in this second category; it is referred to as an external galaxy or as an extragalactic nebula.

The Andromeda Nebula.—Cepheid variable stars were soon recognized among the brightest stars of the Andromeda nebula and, since their intrinsic luminosities are known fairly well, it is possible to compute the distance of the galaxy as roughly 1,500,000 light-years. It is the largest of the nearer external galaxies and is faintly visible to the naked eye as a small luminous patch in the sky. On well exposed photographs it shows beautiful spiral structure around a large, bright central mass. There are also great rifts of dark obscuring matter analogous to the dark clouds in our own galaxy. Spectroscopic observations show that Andromeda is rotating with the central portions moving like a wheel and the outer portions lagging behind. The overall dimensions are comparable to those of the Milky Way system. (*See* ANDROMEDA.)

Other Galaxies.—Perhaps 1,000,000,000 galaxies are within reach of the 200-in. Palomar telescope. Several thousand are close enough to show details of their structure; they vary widely in appearance. There are chaotic mottled-looking systems named irregular galaxies, such as the Clouds of Magellan in the southern sky; these irregular galaxies make up 2%–3% of the total number. There are also perfectly smooth symmetrical systems called elliptical galaxies, which constitute about 20% of the total number; these galaxies show no trace of interstellar dust or gas and have no young blue stars. The great majority of galaxies, however, show some evidence of spiral structure. It is believed that the irregular galaxies are the youngest, and the elliptical galaxies the oldest; it is possible to divide the spiral types into age groups.

The Expanding Universe.—With the 200-in. Palomar telescope it is possible to photograph galaxies at a distance of approximately 2,000,000,000 light-years. The most remarkable single feature of the universe of galaxies is its expansion. Individual galaxies may show wide diversity in their motions; but statistically, the farther the galaxy is situated from the Milky Way system, the more rapidly it is receding. Recession speeds of more than 35,000 mi. per second have been observed.

Quasi-stellar Objects and Quasi-stellar Galaxies.—Two new types of objects have been discovered which are, as yet, not well understood. The so-called quasi-stellar objects (QSS) cannot be distinguished on photographic plates from ordinary faint, very blue stars; however, they are sources of intense radio waves and they are receding from the earth at such enormous velocities that it is inferred they must be exceedingly distant and unusually luminous objects. Relatively few of these objects are known. The quasi-stellar galaxies (QSG) are much more numerous and resemble the QSS except that they emit no radio waves.

5. **Astronomical Instruments.**—For the great variety of astronomical investigations many types of instruments have been devised. Two principal types of optical receiving instruments are used; those which collect light through large lenses, known as refracting telescopes, and those using concave mirrors, known as reflecting telescopes. Similarly, there are two principal types of radio receivers; those depending on an array of half-wave dipoles, and those which use a small antenna at the focus of a parabolic reflector, known as a radio "dish." Since radio waves are 1,000,000 times as long as optical waves, it is necessary that radio receivers be very much larger than telescopes to obtain satisfactory resolution. Thus, the largest optical reflector has a mirror 200 in. across and the diameter of the lens of the largest refractor is only 40 in., whereas the largest radio dish is 1,000 ft. in diameter. Many kinds of auxiliary equipment are also used, such as interferometers, spectrographs, polariscopes and photometers.

Telescopes for Amateurs.—The amateur should choose his telescope according to the uses he has in mind. A small refractor with a 2-in. objective lens is more easily handled than is a reflector. However, most amateurs soon outgrow such a telescope and desire more light-gathering power. A 6-in. reflector is very satisfactory if it has an equatorial mounting and a driving clock, the entire apparatus weighing less than 50 pounds. The equatorial mounting enables the observer to point to an object whose position on the sky is known although it is not visible to the naked eye; the driving mechanism compensates for the earth's rotation and keeps the object in the field of view, even permitting photography if desired.

ASTRONOMY, RADIO: *see* RADIO ASTRONOMY.

ASTRONOMY, SOCIETIES OF. This article lists the major astronomical societies, professional and amateur, that have been founded throughout the world together with their publications.

The Royal Astronomical society was founded in 1820 as the Astronomical Society of London and was incorporated March 7, 1831. Its headquarters are at Burlington house, London, and *Memoirs of the Royal Astronomical Society* (1882 *et seq.*) and *Monthly Notices of the Royal Astronomical Society* (1827 *et seq.*) are published.

The International Astronomical union, organized at Brussels in 1919, has held meetings in Rome (1922), Cambridge, Eng. (1925), Leiden, Neth. (1928), Cambridge, Mass. (1932), Paris (1935), Stockholm (1938), Zürich (1948), Rome (1952), Dublin (1955) and Moscow (1958). *Transactions of the International Astronomical Union* have been published following each meeting.

The American Astronomical society was originally founded in 1899 as the Astronomical and Astrophysical Society of America, and has published the *Astronomical Journal* since 1944. The Astronomical Society of the Pacific was founded in 1889 and publishes *Publications of the Astronomical Society of the Pacific* (1889 *et seq.*) and *Leaflet* (1925 *et seq.*). The American Association of Variable Star Observers, composed mostly of amateur astronomers, was organized in 1911. It publishes the *Quarterly Report of Variable Star Observation* and the *Bulletin*.

Other astronomical societies and their publications: British Astronomical association, *Journal of the British Astronomical Association* (1890 *et seq.*), *Memoirs of the British Astronomical Association* (1893 *et seq.*) and *Observer's Handbook* (1908–21); Royal Astronomical Society of Canada, Toronto, Ont. (1890), *Transactions* (1890), *Proceedings* (1902) and *Journal of the Royal Astronomical Society of Canada* (1906 *et seq.*); Société Astronomique de France, Paris (1887), *Astronomie* (1911 *et seq.*); Königliches Astronomisches Recheninstitut, Berlin (1897); Astronomische Gesellschaft, Hamburg (formerly in Leipzig; 1863), *Publikationen der Astronomischen Gesellschaft, Leipzig* (1865–1912) and *Vierteljahrsschrift der Astronomischen Gesellschaft, Leipzig* (1866 *et seq.*); Società Astronomica Italiana, Milan (1920), *Memorie della Società astronomica italiana, Rome* (1920 *et seq.*); Société Belge d'Astronomie, de Météorologie et de Physique du Globe (1895), *Ciel et Terre* (1880 *et seq.*); Société d'Astronomie, Antwerp (1905), *Gazette astronomique* (1908 *et seq.*); Sociedad Astronómica de México (1902), *Boletín de la Sociedad astronómica de México* (1902 *et seq.*). (F. K. E.)

ASTROPALIA: *see* ASTYPALAIA.

ASTROPHYSICS is a science concerned with the physical properties of the celestial bodies. It is a part of physics because it provides new information on (1) the behaviour of matter and radiation under conditions of temperature, pressure, magnetic force and gravitation that cannot be realized in a laboratory; (2) laws of nature discovered in the laboratories when such laws operate over very long intervals of time (up to several billion years) and over enormous distances (up to about 30,000,000,000,000,000,000 mi.); (3) the existence of new laws of nature which might remain forever undetected under terrestrial conditions. Astrophysics is also a part of classical astronomy because it derives much valuable information from measurements of the motions of stars, nebulae, planets, satellites, etc., all of which constitute the subject matter of "positional astronomy." It depends upon chemistry for the study of the behaviour of various types of molecules in the atmospheres of the planets and the cooler stars, the formation of simple molecules and dust (or smoke) particles in interstellar space, the internal constitution of the planets and the chemical composition of meteorites.

Astrophysics is related to geology and geophysics, not only in the study of the surface features of the moon with its meteoric craters, extinct volcanoes and mountain chains, but with the interpretation of the surface markings of the planet Mars and the "red spot" of Jupiter. There is also a connection with biophysics, especially with regard to the origin and evolution of living organisms on the earth and (probably) on other planets in our solar system and on planets belonging to the families of other stars.

Mathematics is an important tool in nearly all branches of astrophysics; many modern mathematical theories have found applications to the study of stellar atmospheres and interiors and of the evolution of stars and nebulae, and certain astrophysical problems have stimulated new research in analytical mathematics. Several complicated problems of stellar pulsations and stellar evolution would have remained intractable were it not for the development of fast electronic computers of different types which are capable of performing in a few hours calculations that would require many thousands of hours of work with ordinary desk calculators.

Engineering knowledge and skill are of the utmost importance in the construction of astrophysical instruments. The parabolic mirror of a large reflecting telescope must be true to shape at every point of its surface to better than one-millionth of an inch, and it must be so supported in its cell that it is not perceptibly distorted by the elasticity of the glass in any of its orientations; thermal distortion must be eliminated through the use of low expansion glass, such as Pyrex, and by means of special devices that prevent rapid temperature changes in the observatory dome. The mounting of the telescope must be balanced in all positions and must be provided with a guiding mechanism that will automatically follow the apparent rotation of the celestial sphere around the observer. Electronics plays an important role in the construction of photoelectric photometers that are capable of recording the light of a star too faint to be registered on a photographic emulsion with the largest existing telescope (stellar magnitude about +24) and of measuring changes in brightness of a variable star amounting to only 0.001 stellar magnitude (the human eye can detect changes of the order of 0.1 magnitude; the photographic emulsion gives at best a precision of about 0.04 magnitude). Various modifications of commercial television techniques are used for the construction of electronic "image convertors" which record on a screen (or a photographic emulsion) a photoelectric image of an entire field of stars and nebulae.

New engineering problems constantly arise in the construction of different types of radio telescopes. The largest steerable parabolic antennas are exceedingly heavy and must be so built that they will not sag in any orientation. Their electronic receivers must be of the highest sensitivity and must be accurately tunable to any predetermined frequency. Special types of radio telescopes, such as the "Mills Cross" in Australia, consist of separate arrays of small antennas with each beam of the cross about one mile in length. Entirely new engineering problems arose in connection with the exploration of outer space from artificial earth satellites and other space vehicles. Astrophysical instruments had to be designed to fit within the permissible limits of weight and cubic footage inside a space vehicle, and to withstand shock during the fast acceleration of the rockets in the launching process. Telemetering devices had to be designed to radio back to the earth the readings of the instruments, and a source of power in the form of solar batteries had to be constructed to operate the telemetering devices.

The word "astrophysics" is of relatively recent origin. Although it had been used occasionally by several astronomers since the middle of the 19th century, it became a standard expression through the efforts of George Ellery Hale, in the United States, who founded, at Williams Bay, Wis., the Yerkes observatory of The University of Chicago in 1892 and, near Pasadena, Calif., the Mt. Wilson observatory of the Carnegie Institution of Washington in 1904 as astrophysical research centres, and who started the *Astrophysical Journal* in 1895 as the world's most distinguished "international review of spectroscopy and astronomical physics." Although the word did not exist, the study of astrophysics began long before the middle of the 19th century. Much of the work of Galileo (his drawings of sunspots, of the ring of Saturn and of the map of the moon) was pure astrophysics, and so was Sir Isaac Newton's work on optics. An important new stimulus for the study of astrophysics came in 1814 when Joseph von Fraunhofer started observing the spectra of the stars with a simple spectroscope. It came into even greater prominence in the third quarter of the 19th century when William Huggins in England and Angelo Secchi in Italy started classifying the spectra of the stars, and toward the end of the century when H. C. Vogel in Germany introduced photography into the field of stellar spectroscopy and started measuring the radial velocities of the stars from the Doppler displacements of their spectral absorption lines. Since about 1950 there has been a trend to replace the photographic emulsion by a photoelectric surface and to "scan" the spectra of the celestial bodies in order to take advantage of the enormous sensitivity of the photoelectric cell to small differences in the intensity of the radiation.

During the 100-year period of modern astrophysics we detect chronologically five principal stages of development:

1. From about 1859, when G. Kirchhoff identified the element sodium as the source of a close pair of yellow absorption lines in the solar spectrum, until about 1888, the main emphasis in astrophysics was to observe, record and classify the great variety of stellar and nebular spectra (including those of the sun and planets).

2. From 1888, when Vogel succeeded in obtaining high-resolution photographs of stellar spectra, until about 1915, most astrophysicists were primarily interested in measuring radial velocities of stars, in studying the spatial arrangements of the stars in our galaxy and in discussing the kinematical properties of the stellar system in the vicinity of the sun.

3. From about 1915, when W. S. Adams and A. Kohlschütter discovered the correlation between the luminosities of the stars and the intensities of certain pressure-sensitive absorption lines in stellar spectra, until 1930, there was a return to a problem previously studied by N. Lockyer and others; namely, the determination of the abundances of the chemical elements in different celestial objects. This stage culminated in the now-famous "ionization" theory of Meghnad Saha, E. A. Milne, H. N. Russell and many others, which led to the establishment by Russell of a reliable table of atomic abundances in the sun that was then often, but incorrectly, labeled as the "cosmic abundance scale of the elements."

4. Between about 1930 and 1950 astrophysicists finally succeeded by various methods (some purely observational and others theoretical in character) in discovering large differences in the chemical compositions of many stars and nebulae. Russell's solar abundances, though amply confirmed and improved upon by later workers, are approximately duplicated in many stars of the "main sequence." But there are many other stars which are rich in helium and poor in hydrogen, and there are others in which some other chemical elements (for example, lithium or technetium or carbon) are much more abundant than in the sun, while other ele-

ments are less abundant.

5. Since 1950 the most spectacular development has been the unraveling of the principal processes of stellar evolution and the recognition of "evolutionary tracks" of stars in the Hertzsprung-Russell diagram (in which the intrinsic luminosity of each star, or its total energy production, is plotted against its surface temperature, or colour equivalent). The phenomenal success of this work (which is based upon earlier work by A. S. Eddington, S. Chandrasekhar, R. J. Trumpler, G. P. Kuiper and many others) was primarily associated with the names of M. Schwarzschild, B. Strömgren, F. Hoyle, A. Sandage and others. It rests upon the recognition that certain groups of stars, the galactic and globular star clusters, have different H–R diagrams and may be arranged into a sequence of different ages: the youngest clusters, such as the double cluster in Perseus, may be only a few million years old; the oldest, such as Messier 67 and all the globular clusters, are five or six billion years old. We reason that a young star, such as Vega in the constellation Lyra, may after several hundred million years resemble Deneb in the constellation Cygnus. The former is a main sequence star with a central temperature not much above the 20,000,000° central temperature of the sun; the latter is a supergiant with a central temperature of perhaps several hundred million degrees—or even one billion degrees, at which many nuclear processes are active in producing the heavy elements of the periodic table. We believe that the supergiant will probably ultimately become a "subluminous" blue star with an atmosphere containing mostly helium and heavier gases and little hydrogen. It may even become a "white dwarf" (a celestial body of planetary dimensions and of immense density) after one or more explosive processes of the nova or supernova outburst type. The important thing about this stage of astrophysical thought is that it is not based upon observing the very slow evolutionary change in any individual star but upon comparing several different stars which are believed to be of different ages but nearly identical masses. (The present theories of stellar evolution predict only a very small loss of mass, less than 1%, as a result of the conversion of mass into radiation by nuclear fusion.)

If we are permitted to speculate upon what the next stage of astrophysics will be, it is reasonable to expect: (1) that with the development of space science there will be at first a reversion to the character of the first stage—the more or less chaotic accumulation of many new and unexpected observational results and discoveries such as have already been made by means of high-flying rockets; these have given totally unexpected data on the extreme ultraviolet spectrum of the sun and of certain new kinds of nebulae (for example, the one surrounding the star Spica in the constellation Virgo) and on the existence of luminous hydrogen atoms in interplanetary space; and (2) that methods will be developed to record systematic evolutionary changes in a few individual stars. If a star like Vega or, in this context, a star like β Canis Majoris, should ultimately become a supergiant it must increase in radius and volume. We cannot measure the change in radius directly: it is much too small to be detected after intervals of hundreds or even thousands of years. But if such a star vibrates—and β Canis Majoris does vibrate, with a period of six hours—then as the volume increases the period of the vibration should become longer. The precision with which the period can be measured is so great that even a minute change in radius—say one that may occur after 50 or 100 years—should produce a measurable increase in the period.

The field of astrophysics is highly diversified. It is, therefore, useful to subdivide it into several groups, according to some suitable criteria. The conventional criterion is that of the method employed in carrying out the research. On this basis we distinguish between observational and theoretical astrophysics. The former is conducted at 100 or more observatories and other research centres distributed all over the earth. In most of them use is made of the light-gathering power of a telescope, such as a parabolic reflector, in order to concentrate as much radiation as possible from a faint astronomical source in a small spot in the focal plane. This radiation is then analyzed with various types of auxiliary instruments—a photographic plate placed directly in the focal plane of the telescope to obtain a direct picture of the object, the photoelectric surface of a photometer to measure the brightness of the source, a radiometer to record the heat (in all wave lengths transmitted by our atmosphere) of the source or the slit of a spectrograph which disperses the radiation into its constituent wave lengths. Although the light-gathering power of the telescope is usually its most important property, the scale of the image in the focal plane (or for visual observations the magnification) also may be important. For example, the scale of the 40-in. refractor of the Yerkes observatory is 10 sec. of arc per millimetre. A small nebula, such as the Ring nebula in Lyra, may thus be investigated not only in its integrated light (as would be the case with a telescope of short focal length) but with respect to its structural details. There are, however, some special fields of observational astrophysics in which the telescope plays little or no role. In solar research, because of the brilliance of sunlight, the scale of the image is often more important than the light-gathering power. Hence, many solar tower telescopes have small apertures (12 in. at Mt. Wilson) but very great focal lengths (150 ft. at Mt. Wilson). The very long-wave radio radiation of astronomical sources often requires for its study antennas which so little resemble an ordinary telescope that it requires an unusual imagination to think of them as radio telescopes. Finally, for the study of cosmic rays and of the chemical composition of meteorites, and for the measurement of X-ray radiation from the sun, no telescopes of any kind are required.

Theoretical astrophysics is usually conducted in university departments which have no large telescopes and auxiliary instruments. But the work of the observational and the theoretical astrophysicist often overlaps. In fact, the conventional division into an observational and a theoretical branch is quite unsatisfactory. It is true that some theoreticians have claimed that the properties of the universe could have been predicted from a systematic, theoretical discussion of the known laws of nature. Yet, it is doubtful that by this process even the existence of stars in the universe could or would have been predicted. Equally unrealistic are the claims of those observers who believe that all important discoveries were "unexpected." It is true that some discoveries were not predicted by theory, and the observer must at all times be prepared to find something entirely new on his records. But it is equally true that some of the greatest advances were the result of searching for effects that had previously been predicted by a theoretician. Among the most spectacular discoveries of this type was W. S. Adams' measurement of the gravitational red shift of the lines of the white-dwarf companion of Sirius, a phenomenon which had previously been predicted by Einstein's theory of relativity.

On the other hand, the discovery by A. Hiltner and J. S. Hall of the interstellar polarization of the light of very distant stars was totally unexpected and came as the result of a search for stellar polarization (produced in the atmosphere of a partially eclipsed star) which had been predicted by Chandrasekhar and is also known to exist.

It is probably better to subdivide the field of astrophysics into several branches according to the nature of the problem under study rather than the method of investigation. On this basis astrophysics can be subdivided into the following fields:

Solar physics, including the structure of the sun's atmosphere and interior; solar activity; nuclear processes inside the sun and on its surface; solar magnetism; solar-terrestrial relationships; and cosmic rays from the sun.

Physics of the solar system, including the physical properties of planets, satellites, comets, zodiacal light and interplanetary gas; cosmogony.

Physics of the stars, including stellar atmospheres and interiors, energy generation by nuclear processes; stellar origin and evolution; distribution of stars in the Milky Way and their kinematical properties; star clusters and population differences; stellar magnetism and rotation; abundances of the elements.

Physics of the interstellar medium, including properties of gas and dust in the Milky Way and their chemical composition; polarization of starlight produced by interstellar dust; reddening

of starlight; distribution in the spiral arms of the Milky Way; interaction between stars and interstellar medium; distribution of cold hydrogen from radio observations of the 21-cm. emission line; gaseous nebulae.

Peculiar stars, including novae and supernovae; radio emission and visible light produced by synchrotron radiation from the Crab nebula and other old supernovae; high-energy cosmic rays from old supernovae; pulsating variable stars; binaries and multiple stars, including the evolution of close pairs which lose mass to interstellar space.

Galaxies, including structure and evolution of the Milky Way and other galaxies; the distance scale of the universe and its age; the problem of the expansion of the universe and the "cosmological constant"; interaction between close pairs of galaxies and processes in colliding galaxies; the mysterious "central nucleus" of the Milky Way and the outflow of cold hydrogen from the central bulge; intergalactic matter; origin of spiral arms in galaxies.

Since astrophysics is closely connected with physics it is of interest to discuss by means of several examples the three aspects mentioned in the first paragraph of this article.

The behaviour of matter and radiation under physical conditions that cannot be realized in a laboratory:

1. The internal temperature of the sun is about 20,000,000° and the density is roughly 150 g. per cubic centimetre. Under these conditions hydrogen is fused into helium at a rate which is given by the energy production of the entire sun, 4×10^{33} ergs per second. Very massive stars—about 50 times the mass of the sun—produce about 1,000,000 times as much energy per second as does the sun.

2. A white dwarf (like the companion of Sirius) has a mass resembling that of the sun, but a radius more nearly resembling that of the earth. Hence its *mean* density is about 1,000,000 times greater than the mean density of the sun, which is 40% greater than the density of water. At such enormous densities gases are said to be "degenerated," and obey an equation of state which differs from that of a "perfect gas."

3. The elements lithium, beryllium and boron are of very low abundance on the earth and in the atmosphere of the sun. Presumably they have mostly disappeared because of the relatively low temperatures (of the order of a few hundred thousand degrees) that are required to cause their nuclear transformations. But in the atmospheres of some stars the lithium lines are very strong. It is probable that surface phenomena on the stars, and even on the sun (perhaps those associated with the magnetic fields of sunspots), result in the production of new lithium atoms to replace those that disappear through the action of thermonuclear reactions.

4. The density of the interstellar gas is on the average about one hydrogen atom per cubic centimetre (or about 10^{-24} g./cm.^{3}). The temperature of the gas in some regions may be about 10,000° K. The state of ionization and excitation of such a gas differs greatly from that encountered under conditions resembling thermodynamic equilibrium.

The operation of known laws of nature at great distances and over long intervals of time:

1. The properties of the force of gravitation can best be examined by means of astronomical observations. Newton proved that this force keeps the moon in its orbit around the earth, and the planets in their orbits around the sun. The same law acts between the component stars of binary systems, and determines the galactic orbits of stars around the galactic nucleus. It almost certainly acts between galaxies, and causes remarkable tidal disturbances (or "bridges") between neighbouring galaxies. Observations of solar eclipses over several thousand years show that the force of gravitation is not absorbed by intervening bodies, and that the force is independent of the composition or the physical state of the attracting bodies. Nothing is as yet known regarding the speed of the propagation of the gravitational force but, presumably, astronomical observations alone could be used to study this question. Einstein's modification of the Newtonian concept of gravitation has been verified by means of astronomical observations (gravitational bending of light rays passing close to the sun, red shift of spectral lines, advance of the perihelion of Mercury).

Important experiments on the gravitational measurement of time may be carried out by means of two atomic clocks, one located in an artificial earth satellite, the other on the surface of the earth.

2. The constancy of the velocity of light in a vacuum from moving sources and for all wave lengths has been established from observations of distant spectroscopic and eclipsing binaries.

3. The effect of aberration of light has also been established by means of observations of distant stars and galaxies.

New laws of nature:

1. The most spectacular effect of this sort, presumably involving a new law of nature, concerns the observed recession of the galaxies and has led to the theory of the expanding universe. The red shifts of the spectral lines of distant galaxies have been found by A. E. Lilley and E. F. McClain to be proportional to the wave length over an interval of 500,000 to 1 in the electromagnetic spectrum (between wave lengths of about 4,000 Å and 21 cm.). This is the law of the Doppler effect.

2. Astronomical observations may lead to the discovery of a new law involving the phenomenon of "continuous creation" of matter as suggested by F. Hoyle and others. It may even be possible to establish how the local environment (spiral arms of galaxies, magnetic field, etc.) influences this process.

3. Astronomy, more than physics, is concerned with the ultimate fate of the radiation emitted into space by billions of stars in billions of galaxies: Does it disappear forever and is the aging process of the universe irreversible?

ASTURA, a tiny peninsula on the Tyrrhenian coast approximately 37 mi. S.E. of Rome, was once an island; a river of the same name enters the sea a few hundred yards east of the peninsula. Astura was a station on the Via Severiana, the coast road from Anzio to Terracina, and the present castle is built on the foundations of a Roman villa, with fish tanks and harbour still preserved. The Frangipani built the medieval castle, where Conradin, grandson of Frederick II of Hohenstaufen, sought refuge after his defeat at Tagliacozzo in 1268. Giovanni Frangipani, owner of the castle, betrayed Conradin and handed him over to Charles of Anjou, to be beheaded in Naples. In Roman times there were several villas along the coast between Astura and Antium (Anzio). According to Suetonius, both Augustus and Tiberius contracted malaria there, of which they died. (G. Kh.)

ASTURIAS, a region of Spain consisting of the northern half of the modern province of Oviedo, was, from 718 to 910, the only independent Christian kingdom in the Iberian peninsula. The kingdom was formed by a number of Visigothic nobles and officials who, after the Muslim invasion of Spain, retired to this area, as high mountain ranges to the east, south and west made it a small and easily defended enclave. They elected Pelayo, a Visigothic prince, as king and set up a capital at Cangas de Onís. The new kingdom managed to survive repeated attacks by the armies of the amirate of Córdoba and extended its frontiers to include Galicia and Cantabria before the end of the 8th century. The capital was transferred first to Pravia (*c.* 780) and thence, in the reign of Alfonso II (791–842), to a strategically sited new city constructed for the purpose at Oviedo. During the reign of Alfonso III (866–910) the frontiers of Asturias were pushed south to the line of the Duero from the Atlantic to Osma. By this time, the kings of Asturias, with the aid of Mozarab (Christian) immigrants from the amirate, commanded sufficient manpower to garrison and repopulate the areas south of the Asturian mountains. The kings made alliances with dissident Muslim leaders and sometimes established a *modus vivendi* with the amirs of Córdoba, but always retained their independence. An important

factor in building up a sense of national identity was the discovery, early in the 9th century, of the supposed tomb of St. James at Padrón, in Galicia. The shrine subsequently established at Santiago de Compostela was soon to become the spiritual centre of the nation. By the 10th century the kingdom was too large to be effectively controlled from the mountain capital at Oviedo, and García I (909–914) made León his administrative centre in 910.

Self-conscious Visigothicism was a feature of the Asturian kingdom, whose princes claimed direct descent from the Visigothic rulers of Spain and whose earliest chroniclers stressed the duty of the kingdom to proceed to the early and total reconquest of the whole peninsula. Church organization was re-established on the Visigothic model, aided by the immigration of Mozarabic priests, and the many churches built in Asturias adhered closely to Visigothic architectural tradition. Similarly the secular administration of the Asturian kings continued, although in attenuated form, the system of the Visigothic rulers, and the *Forum judicum* remained the basis of Asturian law. Some Frankish influence is evident in the administration and in architecture, and there are traces of diplomatic contacts with Charlemagne and his successors, but, generally, the Asturian kingdom lived in total isolation from the rest of Christian Europe.

Asturias was created a principality by John I of Castile for his eldest son, Henry, in 1388. This principality survived during the existence of the Spanish monarchy as a title (in modern times purely honorific) borne by the sovereign's eldest son. *See* also SPAIN: *History*.

See L. Barrau-Dihigo, "Recherches sur l'histoire politique du royaume asturien (718–910)," *Revue hispanique*, vol. lii (1921); R. Menéndez Pidal (ed.), *Historia de España*, vol. vi (1956). (P. E. R.)

ASTYAGES (Babylonian ISHTUMEGU) (reigned *c.* 584–*c.* 550 B.C.), the last king of the Median empire. According to Herodotus, he was the son of Cyaxares and reigned 35 years; his wife was Aryenis, the daughter of Alyattes of Lydia; and Cyrus (*q.v.*) of Persia was his grandson through his daughter Mandane. The relationship with Cyrus is probably legendary, but the Harpagus who figures in Herodotus' account as a general of the Median army who went over from Astyages to Cyrus seems to be a historical person, as the family of Harpagus afterward held a high position in the Persian empire. According to Babylonian inscriptions Cyrus, king of Anshan (in southwestern Iran), began war against Astyages in 553 B.C.; in 550 the troops of Astyages rebelled and he was taken prisoner. Then Cyrus occupied and plundered Ecbatana, the Median capital. Herodotus states that the captive king was treated fairly by Cyrus. The story of the war was also related by Ctesias, according to whom the leading figure in the insurrection against Astyages was Oebares, known from Babylonian sources as Ugbaru. Ctesias says that Astyages was made satrap of Barcania or Hyrcania by Cyrus, but was later slain by Oebares. (I. M. D.)

ASTYPALAIA (Italian STAMPALIA, modern ASTIPÁLAIA, Latin ASTYPALAEA), an island of the Dodecanese (*q.v.*), Greece, lies 80 mi. (129 km.) WNW of Rhodes. Pop. (1961) 1,539; area 37 sq.mi. (97 sq.km.). Perhaps a Cretan possession before 1400 B.C., it was later colonized by Dorians from Epidaurus (not Megara as one tradition says). As a member of the Athenian empire its annual tribute of two talents is evidence for a modest prosperity, probably agricultural. Although for a time subject to Macedon and Egypt, it remained on the whole independent, even during the supremacy of Rome, whose fleet used its harbours against the pirates (after 105 B.C.). The Venetian family, the Quirini, who held the island in the Middle Ages, built the fortress (now restored) which dominates the chief town, Castello (Astropalia or Astipálaia), on its southeast shore.

See Inscriptiones Graecae, xii (2), the main evidence for the history and antiquities of the island; L. Ross, *Reisen* (1841). (W. G. F.)

ASUNCIÓN, capital and port of the republic of Paraguay, on the eastern bank of the Paraguay river near its confluence with the Pilcomayo. The population of the city (1962) was 305,160. The surrounding district is a rich agricultural and pastoral area producing cotton, sugar, maize, tobacco, fruit and cattle products.

Asunción is built on a picturesquely wooded red sandy promontory (the westernmost point of the Paraguayan extension of the Brazilian plateau) descending to the Paraguay river. Summer temperatures are high, frequently exceeding 100° F., but in winter frosts are not uncommon, although average weather conditions from May to September are warm and relatively dry. Most of the annual rainfall of some 50 in. falls in summer thunderstorms. The city is noted for its abundant and beautiful flowering trees, and for its numerous large parks, especially the Botanical garden along the Paraguay river, the estate of a former president. The architecture of the older part of the city adjacent to the river is colonial in style—one-story, red-tiled, pastel-coloured houses, with trees and creeper-covered patios set in cobbled streets. The centre of the town is well modernized, particularly the Calle Palma with business blocks, stores, amusement places and government offices. The cathedral, the presidential palace and the National Pantheon (a smaller replica of Les Invalides at Paris), all built in the 19th century, and the modern Bank of the Republic are among the notable buildings. The large church of La Encarnación is atop the highest hill in the city centre, but the town is spreading into the surrounding hills. Until 1955 houses were dependent on wells, cisterns and horse-drawn tanks for water supply, but a piped supply was then installed, and a new electricity plant provides adequate power and light for domestic and industrial needs.

River steamers of 9 ft. to 12 ft. draft, depending on seasonal river depths, are the principal means of importing and exporting freight. Some 75% of this trade is handled by a state-owned Argentine company, although a Paraguayan company and some small ocean-going vessels from the Netherlands and Great Britain also serve Asunción. The 1,000-mi. passage to and from Buenos Aires takes three to four days in each direction and considerably increases the cost of goods transshipped by this route. It is also the terminus of the Central Paraguayan railway which connects with the Argentine rail systems via a train ferry across the Paraná river, linking Encarnación with Posadas. Another ferry connection across the Paraguay provides trunk-road communication with Buenos Aires. Its transportation facilities and modern U.S.-built docks and warehouses, although inadequate for its needs, make it the principal distributing centre and export port of the most densely populated region of Paraguay. Its central location and significance as a junction in the southern half of the continent have also made it an important air route point, with regular flights between Rio de Janeiro, Braz.; Buenos Aires, Arg.; Santiago, Chile; La Paz, Bol.; and Lima, Peru. Its industrial plants, while not large, are numerous and active and produce textiles, vegetable oils, footwear, flour, canned meat, beverages, yerba maté, processed foods, small river craft and tobacco products. It is the financial centre of the nation.

As the home of the national government, Asunción has extensive political, military and naval activities and it is the seat of the archbishop of Paraguay. The National University of Paraguay was founded in 1889; among the other educational institutions of the city are the national military academy, a normal school, an agricultural school and a Roman Catholic seminary. The French Salesian order maintains a boys' school (the College of San José), and U.S. Congregational churches maintain a grade school and high school (International college). In all aspects of Paraguay's social, cultural and economic life the significance of Asunción is dominant.

The city was so named when Juan de Salazar y Espinosa, acting for his superior, Martínez de Irala, completed a stockade fort there on Assumption day, Aug. 15, 1537. When Buenos Aires was evacuated in 1541 under attack of the Pampa Indians, the inhabitants joined the earlier colonists in Asunción, which thus became for nearly half a century the headquarters of Spain's colonial activities in eastern South America. As such it furnished 60 Paraguayan Spanish families to the expedition of 1580, sent by the Spanish government to found anew the city of Buenos Aires. With the coming of the Jesuits to Asunción in 1588, the city became the base for the conversion of the Indian population in the mission settlements of the Paraná basin. The Guaraní Indians living in the Asunción district intermarried with the Spanish troops and

colonists and established the mestizo character of the Paraguayan people. After the official separation of Buenos Aires from Asunción in 1617, the latter city declined in importance and, partly because of its remoteness from the mother country, nationalist and separatist movements started early. Independence from Spain and from Argentina was declared in Asunción on May 14, 1811. Its strategic position at the head of a great river system linking its three enemies in the War of the Triple Alliance (1865–70) invited its capture by Argentine, Brazilian and Uruguayan forces in 1868, and it was under Brazilian occupation and administration until 1876. In the succeeding years it has been the scene of more revolutions and *coups d'état* than any other South American capital city. (G. J. B.)

ASVINS (Sanskrit *asvina*), twin Vedic deities, are the gods most frequently invoked after Indra, Agni and Soma. They are gods of light, probably representing the morning twilight or the morning and evening star, although their connection with any definite natural phenomenon is obscure. They are awakened by Dawn, whom they follow across the sky in their golden chariot, and may have been conceived originally as deities who rescued the light of the vanishing sun. They are accompanied by the Daughter of the Sun and are known as "golden-pathed" and "drinkers of honey." They succour the distressed, restoring sight and youth and curing the sick; in this benevolent guise they appear in Brahmanical literature as Nasatya and Dasra. Although Indian in name (literally "horse possessors") they have unquestionable Indo-European parallels in the Greek Dioscuri (*see* CASTOR AND POLLUX) and in Lettish mythology. (J. B.-P.)

ASWAN (ASSUAN), a town of Upper Egypt on the east bank of the Nile, 555 mi. (893 km.) S of Cairo by rail. It is situated opposite Elephantine Island (Jazirat Aswan) below the First Cataract, and has benefited commercially from its position as the southern frontier town of Egypt, being the entrepôt of a substantial trade with Sudan and Ethiopia. Pop. (1960) 48,393. A broad embankment flanks the river and provides the site of the principal buildings, including modern hotels and an English church. Aswan is a popular tourist centre and a winter health resort. It is the capital of Aswan governorate, which has an area of 341 sq.mi. (883 sq.km.), and a population (1960) of 385,350.

On the granite outcrop at the beginning of the cataract 3½ mi. above the town, the Aswan Dam stretches across the Nile and, when full, converts the river for 150 mi. (241 km.) upstream into a vast lake. Completed in 1902, and heightened during 1907–12 and 1929–34, this dam holds back in the late autumn from the tail of the Nile flood about 4,000,000 ac.ft. (4,900,000,000 cu.m.) of water and, with the smaller Jabal al Awliya' (Jebel Aulia) Dam upstream in Sudan, stores the water which permits summer cultivation in Middle and Lower Egypt. When filled, the Aswan reservoir raises the level of the water nearly 120 ft. (37 m.) and submerges for nine months each year a number of islands including Philae with its exquisite temple of Isis. Vessels can negotiate this change of level by locks on the western side. The dam's massive wall of granite, 1½ mi. long, is pierced by 180 sluices which can pass the whole Nile flood practically without checking its flow, permitting the heavy load of silt to be passed through. Once one of the largest dams in the world, the boldness of its design and its enormous benefit to humanity give it a high place in the list of the world's great engineering works. Hydroelectric power installations began operating in 1960.

Four miles above the Aswan Dam is the site of the Aswan High Dam, begun in 1960, with a planned storage capacity of 125,600,000 ac.ft. (154,930,000,000 cu.m.). Designed substantially to increase Egyptian farmland and make the country virtually independent of the annual fluctuations of the Nile, the High Dam, scheduled to be completed by the late 1960s, would flood the valley for about 400 mi. (644 km.) upstream. This necessitated the transfer of about 90,000 Egyptian and Sudanese peasants to new agricultural settlements at Kawm Umbu, Egypt, and Khashm al Qirbah, Sudan.

The High Dam will submerge sites of great archaeological value, notably the temples at Abu Simbel (*q.v.*), so the government of the U.A.R. appealed to UNESCO for help in saving them. A rescue operation involving about 20 temples and shrines was launched in 1960 with the cooperation of many states (*see* NUBIA, *Excavation and Preservation of Nubia's Sites and Monuments*).

A few miles south of Aswan, above the cataract, at Ash Shallal on the east bank opposite Philae, the railway from Cairo terminates and communication with Sudan was maintained by steamer. The High Dam necessitated the replanning of these communications. Extensive deposits of good quality hematite, lying about 30 mi. (48 km.) E of Aswan in the Arabian Desert, are worked and shipped downstream for processing near Cairo. In ancient times Yeb, capital of the frontier nome, the first of the upper country stood on Elephantine (*q.v.*) Island, guarding the entrance to Egypt. Near the granite quarries on the eastern bank, which supplied the material for many magnificent monuments, there grew up another city, at first dependent on, and afterward successor to, the island town. This city was called Swan, the mart, whence came the Greek Syene and Arabic Aswan. Syene is twice mentioned (as Seveneh) in the prophecies of Ezekiel, and papyri, discovered on the island and dated in the reigns of Artaxerxes I (465–424 B.C.) and Darius II (423–404 B.C.), reveal the existence of a colony of Jews, with a temple to Yāhû (Yahweh, Jehovah), which had been founded at some time before the conquest of Egypt by Cambyses II in 525 B.C. In Roman times Syene was strongly garrisoned to resist the attacks of the desert tribes. In virtual banishment, the poet Juvenal, according to one tradition, was sent there by Domitian as prefect. In the early days of Christianity the town became the seat of a bishopric, and numerous ruins of Coptic convents are in the neighbourhood. On the conquest of Egypt by the Turks in the 16th century, Selim I placed a garrison there, from whom, in part, the present townspeople descend. During the Mahdia (1884–99) it was occupied by British and Egyptian troops.

ASYLUM, a place of refuge. The derivation is of interest. In classical Greece it was the right of seizing the ship or cargo of a foreign merchant to cover losses incurred through him, and so came generally to mean the right of seizure or reprisal. In ancient Greece the term meant "the right of sanctuary," so that an asylum was an inviolable refuge for persons in search of protection. All Greek temples and altars were inviolable; that is, it was a crime against religion to remove by force any person or thing once under the protection of a deity. But this protecting right of a deity was recognized by common consent only in the case of a small number of temples. The right of sanctuary appears to have become limited to a few temples in consequence of abuses of it. Asylums in this sense were peculiar to the Greeks. The asylum of Romulus cannot be considered as such. Under Roman dominion the rights of existing Greek sanctuaries were at first confirmed, but their number was considerably reduced by Tiberius. Under the empire the statues of the emperors and the eagles of the legions were made refuges against acts of violence. Generally speaking, the classes of persons who claimed the rights of asylum were slaves who had been maltreated by their masters; soldiers defeated and pursued by the enemy; and criminals who feared a trial or who had escaped before sentence was passed.

With the establishment of Christianity, the custom of asylum or sanctuary (*q.v.*) became attached to the church or churchyard. In modern times the word asylum came to mean an institution providing shelter or refuge for any class of afflicted or destitute persons, such as the blind, deaf and dumb, etc., but more particularly the insane.

ASYLUM, RIGHT OF. In international law the right of asylum designates the protection granted by a state to a foreign citizen against his own government. The person for whom asylum is established, however, has no legal right to demand it, while the state as the agency that has the legal right to grant asylum is under no obligation to give it. Asylum is therefore a right of the state, not of the individual. This right of the state falls into three clearly defined categories: territorial, extraterritorial and neutral asylum.

Territorial.—Territorial asylum is an exception to extradition (*q.v.*), and it is granted within the territory of the state that gives it. It stems from the principle of territorial sovereignty. Occasionally it is granted to fugitives from justice in the absence of

an extradition treaty, and most nations, with the notable exception of the United States and the countries of the British Commonwealth, claim the right to grant asylum to their own nationals. But it is for the protection of persons accused of a political offense that the right of asylum is primarily designed. The category "political offense" specifically includes treason, desertion, sedition and espionage. Moreover, with the signing of the armistice agreement of July 27, 1953, which terminated the war in Korea, it was agreed that a detaining power might grant asylum to prisoners of war not wishing repatriation. The rule that political offenders are entitled to asylum is the product of the development of constitutionalism and democracy in the 19th century, and the usual operating motive is the unwillingness of governments to assume the unpleasant obligation of handing over such refugees to political vengeance in their own countries. Accordingly, most extradition treaties explicitly exempt from surrender persons charged with the commission of political offenses. This generally accepted practice is reflected in art. 14 of the Universal Declaration of Human Rights adopted by the United Nations general assembly on Dec. 10, 1948, which specifically guarantees the right of asylum to those fleeing from persecution. In the sphere of domestic law, the constitution of France adopted in 1946, the constitution of Italy adopted in 1947 and the constitutions of a substantial number of Latin-American countries and of countries behind the "iron curtain" have similarly recognized this right. But in the effort not to enlarge excessively the content of a political offense, it has become a widespread practice to exclude from this category the murder of the head of a state, anarchism, collaboration with the enemy in time of war and, after the Nuremberg trials of 1945, crimes against peace, war crimes and crimes against humanity. Closely related to the last, the Convention on the Prevention of the Crime of Genocide adopted by the United Nations general assembly on Dec. 9, 1948, and ratified by a number of states, provides in art. 7 that genocide is not considered a political offense.

Extraterritorial.—Extraterritorial asylum refers to asylum granted in legations, consulates, warships and merchant vessels in foreign territory. It is therefore granted within the territory of the state from which protection is sought. Its most controversial expression is to be found in the asylum granted in legations, and generally known as diplomatic asylum. The latter was formerly based on the principle of exterritoriality of legations, which meant that the official residences of diplomatic agents were excluded from the territory of the receiving state. It is significant that this principle similarly supported the practice of asylum in consulates and warships. With the abandonment of this fiction, however, diplomatic asylum became a practice founded upon humanitarian grounds when a person's life was in imminent danger from mob or other violence. In an attempt to regulate this practice adequately, the 21 American republics signed a number of conventions carefully defining its scope. Among such efforts, the Havana convention of Feb. 20, 1928, the Montevideo convention of Dec. 26, 1933, and the Caracas convention of March 26, 1954, deserve notice. Significant as these conventions are, they have remained largely unratified, thereby leaving diplomatic asylum without any legal support. Instead, where asylum is practised, it is not a right of the legate state but a custom invoked or consented to by the territorial government in times of political instability. Actually, diplomatic asylum is frequently resorted to in the countries of Latin America, the near and far east and occasionally in Europe, but has never existed in the United States and Great Britain.

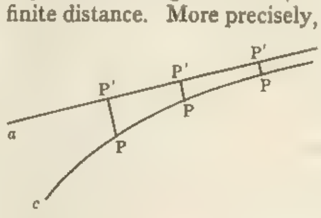
Specific instances of asylum took place during the Spanish civil war of 1936–39, when, it is estimated, between 3,000 and 4,000 persons were given asylum in the embassies and legations at Madrid. Also, on Sept. 20, 1955, the overthrown dictator of Argentina, Juan Domingo Perón, was granted asylum in the Paraguayan embassy in Buenos Aires; and during the Hungarian revolt of Nov. 1956 against the Communist regime, the United States government granted asylum to Joseph Cardinal Mindszenty in its legation in Budapest. This last action is particularly striking, for the United States government strongly disapproves of diplomatic asylum, and its embassies are not authorized to give it unless clearly required by considerations of humanity.

The legality of diplomatic asylum was widely discussed in 1949 when asylum was granted by the Colombian government to Víctor Raúl Haya de la Torre, a prominent Peruvian political figure. Having been indicted for complicity in an unsuccessful attempt to overthrow the Peruvian government in 1948, Haya de la Torre sought and was granted asylum in the Colombian embassy in Lima on Jan. 3, 1949. The refusal of Peru to recognize this asylum, alleging the nonpolitical nature of the offense, led the parties to resort to the International Court of Justice at The Hague for a decision. On Nov. 20, 1950, the International court denied that any general right of diplomatic asylum existed in international law and that if it existed in Latin America it was only on the basis of treaty law and not of customary law. In a decision of June 13, 1951, the court intimated that the asylum granted to Haya de la Torre was illegal and strongly suggested that it be brought to an end. It was not until April 8, 1954, after the controversy had risen to a new pitch of intensity in a flurry of notes and protests from other Latin-American governments supporting the Colombian position, that the Colombian and Peruvian governments reached an agreement permitting Haya de la Torre to leave Peru, thus ending five years and three months of asylum in the Colombian embassy in Lima. Though the case was finally settled, the position of diplomatic asylum remains far from satisfactory.

Neutral.—As regards neutral asylum, a state neutral in time of war is considered to possess the right to offer asylum within its territory to belligerent troops provided they submit to internment for the duration of the war. This matter was regulated by art. 11, 12, 13 and 14 of the Hague convention v of Oct. 18, 1907. Similarly, warships of belligerents have a right to temporary asylum in neutral ports. However, art. 12–19 of the Hague convention xiii of Oct. 18, 1907, provide that in the absence of local regulation to the contrary, the normal period of sojourn in the neutral port, roadsteads or territorial waters is limited to 24 hours. This period, however, may be extended in the case of damaged ships if the condition of the ship is such that more time is needed to repair it. Thus, during World War II, the celebrated German battleship "Admiral Graf Spee," which entered the port of Montevideo on Dec. 14, 1939, in a damaged condition resulting from engagement with enemy war vessels, was granted 72 hours within which to make the necessary repairs. This, however, is a matter largely falling within the discretion of the neutral power. *See* also ASYLUM; SANCTUARY.

BIBLIOGRAPHY.—Manuel R. García-Mora, *International Law and Asylum as a Human Right* (1956); John Bassett Moore, *Asylum in Legations and Consulates and in Vessels* (1892). (M. R. G.-M.)

ASYMPTOTE, in geometry, a line which approaches continually nearer to a given curve, but which does not meet it within a finite distance. More precisely, if a curve, *c*, has an infinite branch and if there is a straight line, *a*, such that the distance PP′ to *a* from a point P on *c* approaches zero as a limit, as P moves toward infinity, then *a* is called an asymptote to this curve. Geminus of Rhodes, writing in the 1st century B.C., remarked that some lines exist which approach indefinitely and yet remain apart. Elsewhere he gives the cases of the hyperbola (*q.v.*) and conchoid, each with its asymptote. The asymptote is often spoken of as a tangent to a curve at a point infinitely distant.



ASYUT, the chief town of a governorate of the same name and one of the largest towns in upper Egypt, is situated on the west bank of the Nile 235 mi. south of Cairo by rail; pop. (1962 est.) 134,000. Important for its schools and as a centre of the Copts, it also has a reputation for its fine pottery, inlaid woodwork, carved ivory, leatherwork and rugs. Just below the town is the Asyut barrage, constructed in 1902, consisting of an open weir of limestone 2,691 ft. long, with 111 sluices each 16½ ft. wide and a lock on the western side. This barrage raises the summer water level of the Nile to feed from its western side the Ibrahimiya canal. It is this canal, nearly 200 ft. wide and 200 mi. long, that

supplies irrigation water to middle Egypt and Al Fayyum. The canal is skirted by a magnificent tree-lined embankment leading from the river to the town.

Asyut is the successor of the ancient Egyptian Syût (later Lycopolis), capital of the 17th nome of upper Egypt and centre of the worship of the jackal-headed god Wepwawet. The habitable part of the governorate is mainly confined to a narrow strip, generally three to five miles wide, flanking the Nile. The town owes its importance to its central position in a broadening of this fertile strip and to being the terminus of a trade route leading to the oases of the Libyan desert and thence to Darfur and Sudan. Modern buildings, including a museum, cover the old city, but the slopes of the limestone hills behind contain a number of rock tombs of which the most important is that of Hepzefa (12th dynasty). Near Badari, about 20 mi. upstream on the east bank, the remains of one of the two earliest known prehistoric civilizations of Egypt have been discovered and named after it the Badarian.

Asyut governorate has an area of 597 sq.mi. with a population (1960) of 1,325,000. *See* NILE. (A. J. AL.; A. B. M.)

ATACAMA, a province of northern Chile noted for mining, was created in 1843. Present boundaries were fixed in 1927. Except for San Félix and San Ambrosio islands, which lie about 500 mi. W. of Chañaral, the province's 30,219 sq.mi. lie within 25° 18′ and 29° 44′ south latitude and 68° and 71° 38′ west longitude. Pop. (1960) 116,309. Although the area is largely desert, scrub vegetation in the south permits pastoral activity. Farming, chiefly in Copiapó and Huasco valleys, is notable for production of fresh and dried subtropical fruits, raisins, and pisco, a distilled drink made from grapes.

The oasis trading centres of Copiapó (*q.v.*) and Vallenar also benefit, respectively, from operation of copper and lead smelters. Ore and concentrates come from scattered, small, locally owned mines or government mills. The foreign-owned 100,000-ton-per-year copper operation at Potrerillos is integrated. Copper reserves at El Salvador and iron ore at Algarrobo promise sustained large-scale mining. Gold and silver, associated with 19th-century provincial wealth and fame, and lead and apatite are secondary to copper.

Chañaral, outlet for Potrerillos, and Caldera and Huasco are ports and rail terminals. (J. T.)

ATACAMA DESERT (DESIERTO DE ATACAMA), a Chilean segment of the west-coast South American arid region that lies between latitudes 5° and 30° S. There are differing concepts as to its areal extent, but the nucleus of the Atacama desert may be identified with the land between the south bend of the Loa river and the mountains separating the Chañaral-Copaipó drainage basins. Elements of coastal range, interior depression and Andean cordillera are present. The straight, abrupt coast may rise 2,000 to 3,000 ft. from the sea or from narrow terraces. The zone of coastal mountains has elevations to 9,000 ft. Hills interrupt the continuity of the longitudinal depression, creating a number of bolsons or basins of interior drainage (2,400–3,000 ft. elevation). The basins, also present in the coastal mountain area, are saline. Among the salts present are the nitrate compounds which give rise to the region's major industry. Across the longitudinal depression the alluvial fans or cones of the Cordillera de Domeyko slope from the east. To the east of the Domeyko range lies a second, higher, structural trough with saline basins (as Salar de Atacama). Eastward of the trough the land is about 10,000 ft., and climate, vegetation, geology and terrain are identified with highland *puna* or altiplano (as Puna de Atacama). The desert has a narrow coastal phase of extremely sparse vegetation. Fog, stratus clouds, high relative humidity and moderate diurnal and annual temperature ranges prevail. Inland the desert is barren, except at higher elevations where infrequent summer showers occur; clear sky, low relative humidity and comparatively wide temperature ranges prevail. It lies within Antofagasta and Atacama provinces (*qq.v.*). The bulk of the Atacama desert was ceded (1883–84) by Bolivia following the War of the Pacific. *See* PACIFIC, WAR OF THE. (J. T.)

ATACAMEÑO (ATACAMA, KUNZA), an extinct American Indian culture of northern Chile and northwestern Argentina. The Atacameñan language (Likan-antai) was possibly related to Diaguita, and J. Alden Mason proposed the joint name Ataguitan. Early assimilated by the Spaniards and seldom mentioned by historians, the Atacameño are known largely through archaeology. They irrigated maize, quinoa, potatoes, squash, beans, cotton and tobacco and kept llamas and alpacas at the rare oases. Their implements were typically of wood, but they traded gold, copper and bronze objects from the north. Villages consisted of rows of stone houses surrounded by a fortifying wall. Each probably was a localized patrilineal clan Lances, clubs, knuckle-dusters, slings, doublets and helmets evidence warfare which was probably defensive. Religion was largely shamanistic; burial, typically in a roofed-over cylindrical cyst.

See Wendell C. Bennett, "The Atacameño," in J. H. Steward (ed.), *Handbook of South American Indians*, vol. 2, pp. 599–618 (1946, 1963). (J. H. So.)

ATACAMITE, a mineral found originally in the desert of Atacama in Chile. It is an oxychloride of copper and its colour presents various shades of green. Some of the finest crystals have been yielded by the copper mines of South Australia, especially at Wallaroo. It occurs also, with malachite, at Bembe, near Ambriz, in west Africa. From one of its localities in Chile, Los Remolinos, it was also termed remolinite. Small quantities of atacamite have been found in Arizona. The basic chloride of copper, it is of frequent occurrence in the green patinas of Egyptian bronzes but is unstable in moist climates. Atacamite has the formula $CuCl_2.3Cu(OH)_2$, and crystallizes in the orthorhombic system. Its hardness is about 3 and its specific gravity 3.7.

ATAHUALPA (ATABALIPA) (*atahu*, "virile," and *allpa*, "sweet") (*c.* 1502–1533), "the last of the Incas" of Peru, so called because he was the last ruler of that great Indian empire, was the favourite son of the Inca Huayna Capac. His mother was Pacchas, the daughter of the conquered sovereign of Quito. His half-brother, Huascar, succeeded Huayna Capac in 1525, for, since Atahualpa was not descended on both sides from the line of the Incas, Peruvian law considered him illegitimate. His father left him, however, the kingdom of Quito. In 1530 a quarrel arose between the brothers over the suzerainty of an interjacent province. Civil war broke out, and by 1532, about the time that the Spanish conqueror Francisco Pizarro (*q.v.*) was beginning his march inland from the coast, Huascar had been defeated and thrown into prison, and Atahualpa had become Inca. Pizarro set out from San Miguel in Sept. 1532 enroute to Cajamarca, a favourite resort of the Incas, where Atahualpa had his headquarters. Messengers passed frequently between them, and the Spaniards on their march were hospitably received by the inhabitants. On Nov. 15 Pizarro entered Cajamarca and sent his brother Hernando and Hernando de Soto to request an interview with the Inca On the evening of the following day Atahualpa entered the great square of Cajamarca, escorted by 3,000 or 4,000 of his followers. who were either unarmed or carried only short clubs and slings concealed under their garments. Pizarro's artillery and soldiers were strategically arranged in the buildings and streets opening on to the square. The interview was carried on by the priest Vicente de Valverde through an interpreter. He stated briefly and dogmatically the history and tenets of the Christian faith and the Roman Catholic policy, and called upon Atahualpa to become a Christian and to acknowledge Charles V as his master. To this extraordinary harangue the Inca pointed out to him vehemently certain difficulties in the Christian religion, acknowledged the obvious greatness of the emperor and declined to accept either Christianity or Spanish sovereignty. He then took the Bible from the priest's hands, looked at it and flung it resentfully to the ground. The priest retired to give an account of the interview to Pizarro, and Pizarro immediately gave the prearranged signal for attack. The Spaniards rushed out from all sides, and the Peruvians, astonished and defenseless, were cut down in hundreds. Pizarro himself seized the Inca, and, in endeavouring to preserve his life, received the only wound inflicted that day on a Spaniard.

Atahualpa, thus treacherously captured, offered in ransom the famous roomful of gold and silver. He fulfilled his promise and the Spaniards received $4,000,000 of bullion, but Pizarro still de-

tained him until reinforcements should arrive. While in captivity Atahualpa was accused of giving secret orders for the assassination of his brother, Huascar, and also of plotting the overthrow of the Spaniards. In February of 1533 Diego de Almagro arrived from the coast; rumours soon spread through the camp of an invasion; and Pizarro ordered the Inca to be brought to trial. He was condemned to death, and, as an idolator, to death by fire, an act of treachery that called forth the protest of the most influential of Pizarro's advisers—except the priest Valverde. But Pizarro feared the anger of his soldiery if he retracted, and Atahualpa, although he professed himself a Christian and received baptism, died by strangulation on Aug. 29, 1533. With him died the Peruvian empire. *See* ANDEAN CIVILIZATION.

The standard authority for these events is still W. H. Prescott's *History of the Conquest of Peru* (1847; 1948). Where there is a discrepancy of opinion, he offers comparisons in his voluminous footnotes. In 1966 a complete English translation by Harold V. Livermore of Garcilaso de la Vega's 17th-century *Royal Commentaries of the Incas and General History of Peru* was published. *See* also J. H. Rowe, "Inca Culture at the Time of the Spanish Conquest" in J. H. Steward (ed.), *Handbook of South American Indians*, Bureau of American Ethnology, bulletin 143, vol. 2 (1946). (W. B. P.)

ATALANTA, a heroine, probably a by-form of Artemis, variously said to be daughter of Schoeneus of Boeotia or of Iasus and Clymene, of Arcadia. She was a renowned and swift-footed huntress. From her complex legend the following incidents are of interest: (1) She was exposed at birth, as her father wanted a son, but suckled by a she-bear (a beast connected with Artemis). (2) She took part in the Calydonian boar hunt (*see* MELEAGER). (3) She offered to marry anyone who could outrun her; those who lost were to be killed. Hippomenes (or Milanion) was given three of the apples of the Hesperides (*q.v.*) by Aphrodite; when he dropped them, Atalanta stopped to pick them up, and so lost the race. Their son was Parthenopaeus, one of the Seven against Thebes. (4) She and her husband, proving ungrateful to Aphrodite, were led to profane a shrine with their loves, for which Cybele turned them into lions.

ATARGATIS, the great goddess of northern Syria; a Greek variant of the name is DERCETO. Her chief sanctuary was at Hierapolis-Bambyce (modern Membidj), northeast of Aleppo, where she was worshiped together with her consort, Hadad, and a youthful male divinity. Her ancient temple there was rebuilt about 300 B.C. by Queen Stratonice, and it was perhaps partly as a result of this royal Greek patronage that the cult, carried by returning Greek merchants and mercenary troops, as well as by Syrian slaves and traders, spread to various parts of the Greek world, where the goddess was generally regarded as a form of Aphrodite. Outside Syria her male companions seldom appear. The Roman west was somewhat less receptive, but Nero was briefly a devotee of the cult, and Roman soldiers carried the Dea Syria (Syrian goddess) even to northern Britain.

Knowledge of the cult derives chiefly from the mock-serious essay of the satirist Lucian, "On the Syrian Goddess," and on the unflattering picture of her mendicant servitors, the self-castrated Galli, in the *Metamorphoses* of Apuleius, books viii–ix. The sanctity of fish, peculiar to her cult, is also attested by inscriptions and archaeological evidence. Her nature closely resembles that of her Phoenician counterpart, Astarte, though as befits her geographical position she also shows some kinship with the Anatolian Cybele. Primarily she is a goddess of fertility, but as the Baalat (mistress) of her city and people she is responsible for their protection and well-being on all scores. Hence she is commonly portrayed wearing the mural crown and holding a sheaf of grain, while the lions who support her throne suggest her strength and her power over nature. *See* also articles on the related figures APHRODITE; ASTARTE; GREAT MOTHER OF THE GODS; ISHTAR. *See* also HIERAPOLIS. (F. R. WN.)

ATASI, HASHIM AL- (HASHEM ATASSI) (1875–1960), Syrian politician who played a leading part in establishing Syrian independence, was born in Homs in 1875, while his country was still part of the Ottoman empire. In early life he held positions in the Ottoman administration. After World War I he was prominent in the short-lived government of Amir Faisal and then became one of the leaders of nationalist opposition to the French occupation and mandate. In 1936 he headed the Syrian delegation which negotiated the Franco-Syrian treaty promising Syria independence, and in the same year was elected president of the republic. The agreement with France broke down and in 1939 he resigned. Following a military coup in 1949 he became prime minister, then again president. The political group supporting him favoured union with Iraq, but this tendency was reversed when in late 1949 Adib Shishakli seized power. Atasi continued in office, but effective power was in Shishakli's hands and in 1951 he resigned. In 1954 a further coup ended Shishakli's regime and Atasi was restored to the presidency. After the 1955 election he retired into private life. He died in 1960.

See S. H. Longrigg, *Syria and Lebanon under French Mandate* (1958); N. A. Ziadeh, *Syria and Lebanon* (1957). (A. H. H.)

ATATÜRK, MUSTAFA KEMAL: *see* KEMAL ATATÜRK, MUSTAFA.

ATAULPHUS (ATAWULF; ATAULF) (d. A.D. 415), chieftain of the Visigoths from 410 to 415, the successor of his brother-in-law Alaric (*q.v.*). In 412 he left Italy and tried to settle his people in southern Gaul. In 414 he married at Narbonne the Roman princess Placidia (sister of the emperor Honorius), who had been captured by the Goths at Rome in 410. Driven from Gaul he retreated into Spain early in 415 and was in that year assassinated at Barcelona. The most important fact known about him is his statement, recorded by Orosius, that his original aim had been to overthrow the Roman empire and replace it by a Gothic empire, but that later, recognizing the savagery of his people, he decided to restore Roman power by means of Gothic arms. His ambition to fuse Romans and barbarians together in a revitalized empire was not realized. (E. A. T.)

ATBARA ('ATBARAH), a town in the Northern province, Sudan, lies on the right bank of the Nile, 195 mi. N. of Khartoum by rail and 201 mi. by river. Pop. (1965 est.) 48,250. It is situated at the point where the Atbara river enters the Nile and is also at the junction of the two main railway lines to Khartoum, from Wadi Halfa and from Port Sudan. The Atbara bridge carries the Khartoum-Atbara line over the Atbara river and is also used by road traffic. The town is the headquarters of the Sudan government railways administration and workshops. There is a cement factory 5 mi. to the south. The occupation of the majority of the inhabitants of the town is connected directly or indirectly with railway services and maintenance. Upstream 12 mi. from Atbara on the Nile is the provincial capital, Ed Damer. (A. EL-S. O.)

ATBARA RIVER (NAHR 'ATBARAH), the last tributary of the Nile, is nearly 500 mi. long. It joins the Nile at the town of Atbara, Sudan, about 17° 40′ N. As the Takazze, the main stream rises near the eastern escarpment of Ethiopia and crosses the northern basalt plateau in a steeply incised ravine which attains a maximum depth of nearly 2,000 ft. only 10 mi. from the river source. After turning north near Debra Tabor the Takazze is joined by numerous large streams which, like itself, run very low or are intermittent from November to May but rise with the summer rains to maximum volume in July and August and carry a heavy load of silt when in spate.

Turning westward to form the southern frontier of Eritrea, the Takazze becomes the Setit and after entering the Sudan is joined by the smaller Atbara to form the main Atbara 310 mi. distant from the Nile. From this point onward the Atbara gains little water from its tributaries, small seasonal *khors*, and after Khashm al Girba it loses volume by evaporation and by seepage into the coarse silt of its own bed, so that the monthly discharge from February to May is negligible. By May most of the visible water has sunk to separate pools used as watering places by the nomads. Even the July discharge into the Nile averages about 700 cu.m. (916 cu.yd.) per second, against 2,150 (2,812 cu.yd.) in August and 1,190 (1,557 cu.yd.) in September, after which it falls rapidly again; but the August figure represents a steady flow amounting to 22% of the total Nile discharge below Atbara.

At the rapids of Khashm al Girba (*i.e.*, "Bottleneck") a dam was being built (1961) for storage of floodwater and irrigation. Firm banks of solid rock at the narrows and locally quarried stone

favour the project, as they did the building of the Butana bridge for the Khartoum-Kassala railway and for cars. Trucks must use the dry-season fords. There is little permanent settlement along the Atbara. The gravels contain some semiprecious stones, but riparian land with fertile new silt is generally lacking, for the bed is cut down into the clay plain, the banks are often badlands and from 10,000,000 to 15,000,000 tons of silt are swept annually straight into the Nile (*q.v.*).

See H. E. Hurst and P. Phillips, "The Topography of the Blue Nile and Atbara," *The Nile Basin* (1950); H. E. Hurst, *A Short Account of the Nile Basin* (1944); H. Bell, *Irrigation by Gravity from the River Atbara* (1956). (M. T. P.)

ATCHISON, a city of Kansas, U.S., 42 mi. N.W. of Kansas City, on the Missouri river; seat of Atchison county. (For comparative population figures *see* table in KANSAS: *Population.*) The surrounding territory is an exceedingly rich agricultural area, and it contains deposits of the loess soil which is especially favourable to fruit growing. The city's industrial establishments include large iron and steel foundries, flour mills and clothing plants. Atchison is an important wholesale centre for hardware, drugs, groceries, athletic equipment, fruit and candy.

At Atchison are St. Benedict's college for men (founded in 1859) and Mount Saint Scholastica college for women (founded in 1863).

Atchison was founded in 1854 by a group of proslavery settlers and was named after their leader, David R. Atchison, U.S. senator from Missouri. The town was chartered in 1858, and the following year a charter was granted for the Atchison and Topeka railroad which later was named the Atchison, Topeka and Santa Fe. A council-manager form of government was adopted in 1921.

ATE, Gr. "ruin," "disaster," including material loss, but coming to mean a state of infatuation in which evil appears good. Personified as a mythological figure, Ate made Zeus take a hasty oath that resulted in Hercules' becoming subject to Eurystheus (*see* HERCULES). Zeus thereupon cast Ate by the hair out of Olympus, after which she remained on earth, working evil and mischief. She is followed by the Litai ("prayers"), the old and crippled daughters of Zeus, who repair the harm done by her (see *Iliad*).

In some Elizabethan writers (*e.g.*, Edmund Spenser) and other moderns she becomes a kind of fiend. (H. J. R.)

ATELLANA FABULA, a kind of farce, popular in republican and early imperial Rome. (*Fabula* was the general term for a play.) The ancients derived the name from the town Atella in Campania; if they were right, then the farces were of Oscan origin, perhaps influenced by the Greek farces of Tarentum and other cities. Strabo mentions that in his own day (in the time of Augustus), although the Oscans had died out, metrical pieces in Oscan were produced on the Roman stage at a certain traditional festival; perhaps he meant no more than that the language was rustic Latin, spiced with Oscan words. According to Livy the *Atellanae* were often acted by amateurs, and to be an actor of *Atellanae* did not involve loss of civic status. Other evidence, however, indicates that the actors may have been professionals. In the last century B.C. the *Atellanae* became a literary genre, and there are some fragments by L. Pomponius of Bononia, Novius and other writers; *see* Otto Ribbeck, *Scaenicae Romanorum Poesis Fragmenta* (Leipzig, 1897–98). There seem to have been four stock masked characters: Maccus, the Clown; Bucco ("Fatcheeks"), the Simpleton; Pappus (in Oscan, "Casnar"), the Old Fool; and Dossennus, whose name (perhaps from *dorsum*) has been taken to mean "hunchback." Manducus, the ogre with champing jaws, is also mentioned by some, but he may not have been an Atellan character. Many of the recorded titles of plays suggest everyday Italian life, but some are reminiscent of the *fabula palliata* (adaptations of Greek new comedy: *see* DRAMA), and some suggest burlesque. The language was rustic and coarse. The *Atellanae* finally disappeared because of the popularity of the mime.

ATESTE: *see* ESTE.

ATHABASCA, a river and lake in midwestern Canada. The river, which lies in the province of Alberta, rises at the continental divide in the Columbia ice field, in the Canadian Rocky mountains, at the southern end of Jasper National park. It flows 765 mi. diagonally across Alberta to Lake Athabasca in the northeast corner of the province. Important tributaries include the McLeod, Pembina, Lesser Slave (which drains the lake of that name) and Clearwater. Navigation above McMurray (formerly Fort McMurray) is limited. The main shipping route is from McMurray (and Waterways, 2 mi. upstream on Clearwater river) via Slave river and Great Slave lake to Mackenzie river and north to the Arctic ocean. Large deposits of bituminous tar sands outcrop for 120 mi. along the Athabasca in the McMurray area.

Lake Athabasca, 208 mi. long and about 32 mi. wide, is 699 ft. above sea level and has an area of 3,120 sq.mi., of which 2,165 sq.mi. are in the province of Saskatchewan and 955 sq.mi. in Alberta. Formerly, the lake extended west to include the basins of Mamawi and Claire lakes, but the Athabasca and Peace rivers, by building deltas into Lake Athabasca, have cut off the two lakes. Athabasca and Peace river waters make the western part of Lake Athabasca turbid. The lake usually begins to freeze in early October; discharge from Athabasca river may open the west end in early May, but ice may linger in the lake until mid-June. Most of the lake is within the geological region of the Canadian Shield with important mining areas at Uranium City and Goldfields. Fort Chipewyan, a small settlement, is on the west end of the lake. (J. R. M.)

ATHALIAH (in the Douai version of the Bible, ATHALIA), in the Old Testament, the daughter of Ahab and Jezebel, and wife of Jehoram (*qq.v.*), king of Judah. After the death of Ahaziah, her son, she usurped the throne and reigned for seven years. She massacred all the members of the royal house of Judah (II Kings xi, 1–3). The sole survivor, Joash, was concealed in the temple by his aunt, Jehosheba, wife of the priest Jehoiada. These organized a successful revolution in favour of Joash (II Kings xi; II Chron. xxii, 10–12, xxiii, xxiv, 7). The story of Athaliah forms the subject of one of Racine's best tragedies. *See* AHAZIAH; JOASH.

ATHAMAS, in Greek mythology, king of the prehistoric Minyae in the ancient Boeotian city of Orchomenus. His first wife was Nephele (*see* ARGONAUTS). Athamas and his second wife, Ino, incurred the wrath of Hera, because Ino had nursed Dionysus. Athamas went mad and slew one of his sons, Learchus; Ino, to escape, threw herself into the sea with her other son, Melicertes. Both were afterward worshiped as marine divinities —Ino as Leucothea, Melicertes as Palaemon. Athamas, with the guilt of his son's murder upon him, was obliged to flee from Boeotia. He was ordered by the oracle to settle in a place where he should receive hospitality from wild beasts. This he found at Phthiotis in Thessaly, where he surprised some wolves eating sheep; on his approach they fled, leaving him the bones. The legend is perhaps founded on a very old custom of human sacrifice among the Minyae.

ATHANARIC (d. 381), a Visigothic chieftain from 364 to 376, who fiercely persecuted the Christians in his territories (approximately the modern Rumania) between 369 and 372. His most famous victim was St. Sabas the Goth. Utterly defeated by the Huns in 376, he fled with a few followers to Transylvania. The bulk of his people, however, took refuge under their leader, Fritigern, in the Roman empire. Athanaric, too, took refuge there in 381, but died at Constantinople a fortnight after his arrival. (E. A. T.)

ATHANASIUS, SAINT, THE GREAT (*c.* 295–373), bishop of Alexandria and doctor of the church, was an Egyptian, probably an Alexandrian, by birth. Associated with the Alexandrian chancery at an early age, he was ordained a deacon by the year 318, with priesthood following shortly after. Despite his early brilliance, it is difficult to believe that he composed his *Sermon Against the Arians* and *The Incarnation of the Word* at this period, as has been claimed. It was during the episcopacy of Alexander of Alexandria

(312–328) that the Arian heresy reached its height. Arius (*q.v.*), an elderly, ascetic priest of Alexandria, had been dealt with by Alexander in a kindly way, but his heretical teaching spread despite his condemnation at a local synod about the year 318. Arius' position was an attempt to explain the doctrine of the Trinity in a Gnostic (*see* GNOSTICISM) or Neoplatonic way, in order to preserve the uniqueness of God the Father and to avoid, as he thought, the heresy of Sabellianism (that is, that the three Persons were only names or modes of the divine nature; *see* SABELLIANISM). Though the doctrine was born at Antioch, where Arius had studied, Alexandria was indeed its proper soil. According to Arius, the Father, Son and Holy Spirit were three separate essences (*ousiai*) or substances (*hypostaseis*); the Father was God in a unique sense, whereas the divinity of the Son and Spirit was only derivative, for they had been created in time. Many of the monks and consecrated women throughout Egypt, as well as the excitable populace of Alexandria, were attracted by Arius' teaching. As the controversy spread beyond Egypt, the emperor Constantine sensed the danger of the religious conflict; his defeat of Licinius in 323 presented a favourable opportunity, and under the pressure of the episcopacy he convoked the first general council of the church at Nicaea in 325. The emperor was hardly a theologian, and his interest was primarily civic peace; his role, therefore, should not be exaggerated, for, if in the matter of the creed he exerted influence upon the hierarchy, it must be admitted that he was also influenced by them. (*See* ARIANISM.)

Athanasius accompanied Alexander to the council as the bishop's private secretary. Despite the remarks of the 5th-century church historian Socrates in his *Ecclesiastical History*, Athanasius' role at this time would appear to have been relatively unimportant; nonetheless, his support of Alexander and the orthodox position won him many future enemies in the Arian and semi-Arian camp. The records of the great council have not been preserved, but some idea of it may be formed from the eulogy on *The Life of Constantine* by Eusebius of Caesarea, from Socrates, Theodoret and fragments of Philostorgius. The account compiled by Gelasius of Cyzicus in the latter part of the 5th century contains much that is untrustworthy. Eusebius, who was present at the council, tells that more than 250 bishops attended; of these, the majority, together with the emperor, sided with the views of Alexander of Alexandria. Arius and his party were condemned and the famous creed of Nicaea, or Nicene creed—which may have been an older Palestinian formula, revised by Bishop Hosius and other Fathers at the council—was finally drawn up (*see* CREED, where it is quoted). The last lines read: "As for those who assert that there was a time when He was not; and that before He was begotten He was not; and that He was made out of nothing; or that He is of a different substance (*hypostasis*) or essence (*ousia*); or that the Son of God is created, changeable, mutable—these men the universal Church declares anathema." (*See* also COUNCIL.)

Although it is an exaggeration to suggest, with Gustave Bardy, that Athanasius found the formula of his life at Nicaea, this was nonetheless the doctrine that was to be at the heart of religious controversy for the next two centuries. Here, too, it is unfair to suggest that in all of this the state was the decisive force; actually the emperors were themselves manipulated by the quarreling factions. As yet, however, the implications of the Nicene doctrine remained undefined: the distinction between homoousios and homoiousios had not yet been established; and the final formula, "Three persons (*prosopa, hypostaseis* in Greek; *personae, hypostases* in Latin), one essence (*ousia, substantia* or *essentia*)," had not yet been theologically canonized.

Philostorgius, an Arian historian, says in his *History of the Church* that "seeing that Arius and his followers refused their assent to the Council, the emperor declared that all who did not accept the common formula were to be exiled." Arius fled to Palestine, but he was far from being subdued. Abetted by sympathetic followers, he circulated his *Thalia* ("Banquet"), a miscellany of songs and other pieces by which he aimed to communicate his heretical message to the masses.

At Bishop Alexander's death in 328, Athanasius, about 30 years of age, succeeded to his uneasy throne over the opposition of Arians and Meletians (*see* MELETIUS). Arius' friend, the wily Eusebius of Nicomedia (*q.v.*), continued to conduct a campaign against the young bishop, especially at the court of Constantine at Constantinople. When Arius in a personal interview had reassured the emperor of his acceptance of the Nicene formula, Athanasius received an imperial order to reconcile all Arians who might wish to make their peace. Still suspicious, Athanasius refused. At the local synod of Tyre, however, in 335, Arius was formally reinstated—he died mysteriously in 336 before he could be reconciled—and Athanasius was banished to Treves in Germany, where he remained until after Constantine's death in 337. This was his first exile. Even after his return his enemies did not remain idle, and he was again banished by a synod held at Antioch in 337; a certain Gregory, "a monster from Cappadocia," as Gregory of Nazianzus calls him, was made bishop of Alexandria in his stead. Athanasius, however, evaded arrest, and with the help of sailors slipped unwatched out of the port and sailed off to Rome to present his case before Pope Julius I. The Roman pontiff submitted the problem to an assemblage of bishops who upheld Athanasius; a council called at Sardica in 343 also declared in his favour; but Athanasius returned to Alexandria only after the violent death of the usurper Gregory in 345.

The ten-year period (346–355) which followed his second exile was one of comparative peace. Athanasius took the occasion to build up Alexandria and the dependent dioceses, appointing many loyal Egyptian monks to episcopal sees. But another blow soon fell. In 355 the emperor Constantius convoked a synod at Milan, and the council, controlled by Athanasius' enemies, once more deposed him. Athanasius tells in his *Apology for My Flight* that more than 5,000 Roman soldiers surrounded the Church of St. Theonas while he was celebrating the sacred liturgy. In the riot which followed, women were attacked and sacred vessels desecrated; but Athanasius managed to escape. This time he took refuge with the fathers of the Egyptian desert, whose way of life he profoundly admired. It was in their honour that he composed the *History of the Arian Heresy*, a curious, forthright book which reflects Athanasius' vehemence as well as his ironic humour. Indeed, to the period of his third exile belong perhaps his greatest works. After Constantius' death in 361, Athanasius returned to his see and straightway convoked a council at Alexandria to reaffirm the doctrines of Nicaea and to conciliate the semi-Arians. The semi-Arians were divided into three main factions, the Anomoeans, the Homoeans and the Homoiousians. The first group, under the leadership of Aetius and Eunomius, were the doctrinal successors of Arius, and taught that the Son was unlike (*anomoios*) the Father; it was against this group that Basil the Great and Gregory of Nyssa (*qq.v.*) wrote important treatises. The second group, under Acacius of Caesarea, remained in favour at the court of Constantius. Acacius seems to have continued the work of Eusebius, his predecessor, and attacked the orthodox group as teaching Sabellianism. The central point of their doctrine was that the Son was distinct but like (*homoios*) the Father. The third group, or Homoiousians, were closest in their teaching to Athanasius and his party. Under Basil of Ancyra, they stanchly opposed the extreme semi-Arians under Eunomius, and attempted to bridge the gulf which separated the heretics from the orthodox. Their differences were primarily of a linguistic sort, and their suggestions were treated by Athanasius with great sympathy, especially in his work *On the Synods* and in the council of 362. The view of the Homoiousians was that the term *homoousios*, "of the same, identical substance," which had perhaps arisen as a translation of the Latin term *consubstantialis*, did not sufficiently stress the distinction between the Persons and thus favoured Modalism or Sabellianism. They therefore wished to substitute the word *homoiousios*, meaning "distinct, but of a similar nature." Unfortunately Basil of Ancyra and his followers tended at the end to deny the divinity of the Holy Spirit, and Athanasius' overtures were in vain. In any case, within a few years the terminological differences were to be reconciled: the Son was *of like nature* because, though distinct, He was *of one substance* with the Father. The Nicene term had absorbed the other. The way was now prepared for the doctrinal advances of the Cappadocians, Basil the

Great, Gregory of Nyssa and Gregory of Nazianzus.

Only by understanding Athanasius' readiness for reasonable compromise can a correct insight into his character and personality be achieved. But the storm was still not allayed. The toleration with which Julian began his reign in 361 was soon transformed into almost hysterical measures in an effort to regenerate the pagan religion. Athanasius was caught up with many other victims of Julian's revivalist whims: in the autumn of 362, the emperor forced him into exile once more—"this notoriously troublesome man," as Julian wrote of him, "and hardly a man." But he was soon to return after the emperor was mortally wounded in June 363. Athanasius enjoyed comparative calm under Jovian (363–364) and Valentinian (364–375); but under Valens, as Theodoret relates, the incense burned once again on pagan altars. In Oct. 365 Athanasius was removed from his see, to remain in exile about four months. Recalled by Valens in Feb. 366, the elderly bishop was at last allowed to live out his life in peace. The end came on May 2, 373 (his feast day is May 2). It had been an incredible chapter in the history of the church.

Great as he was, Athanasius is one of the most tragic figures of early Christianity. A small, energetic man, he was at heart a monk, unworldly and sometimes uncompromising. To the emperors, who were little interested in theological speculation, he represented a storm centre of civil and religious strife. As for his ecclesiastical enemies, it is perhaps not too difficult to understand the religious bickering of an earlier day. In any case, this man, whom Gibbon thought more capable of ruling Rome than all the sons of Constantine, aroused fiercer loyalties and hatreds than any other Father of the church. A contemporary letter preserved in a British museum papyrus (*P. Jews* 1914, ed. by H. I. Bell, 1924) paints him as cruel and despotic; but coming as it does from the hand of a Meletian cleric, it cannot be accepted as totally reliable. In his theological doctrine Athanasius was clear and uncomplicated, more conservative than profound, and gifted with a stubborn sense of tradition. His teaching on the Atonement was intimately bound up with his Trinitarian theology: we are redeemed by Christ's life and death because in Him God and man are united in one Person. The Atonement is achieved by the union of God with man in the life, death and glorification of Christ. Indeed, "if Christ had not of Himself been the substantial image of the Father, He could not have formed the divine image in any man." The actions of Christ belong to both God and man; there are two natures, but one Person. In fighting against the Pneumatomachi, who denied the consubstantiality of the Holy Spirit, he insisted the Spirit was also truly God, "proceeding from the Father through the Son." His extant writings do not deal extensively with sacramental theology; but in an *Epistle to Serapion* he asserts that after the prayers of the liturgy "the bread and wine, which had before been ordinary food and drink, become the Body and Blood of the Lord." Athanasius' theology was fundamentally Pauline and Johannine.

His encouragement of the Egyptian monastic movement had widespread consequences. Whether or not the *Life of Antony* is from his own hand, he was largely responsible for its circulation; through the Latin version made about 361 by Evagrius of Antioch and used, for example, by Augustine, it introduced eastern ascetic ideals to the Latin world. The *Life* is a subtle fusion of historical details and symbolic presentation of the spirit of early monasticism. The core of the work may be found in sec. 16–43, in which a series of discourses are put into the mouth of Antony on the monk's struggle as a "martyr in conscience" against the evil forces of this world, and on the witness he must bear to the truth of Jesus' message until the final coming. Although Athanasius insisted on sobriety and celibacy, he emphasized the importance of moderation and the internal spirit in the tradition of Methodius' *Symposium on Chastity*—a work on which, incidentally, the pseudo-Athanasian *Life of Syncletica* in part depends. Athanasius' authentic doctrine is focused on the restoration of the divine image in man: this is ideally achieved by the practice of evangelical perfection; and the union with the Word, he teaches, will bring about a special illumination of the mind as well as the conquest of man's lower impulses. Thus his ascetic teaching is a logical complement to his doctrine on the Trinity and the Atonement. The divine image impressed on man at creation had been destroyed—or at least tarnished—by man's estrangement from God. Thus an authentic model must once more be presented to the human race; and this was achieved by the Incarnation and Atonement. The Word, as true God is both the exemplar and the cause of our redemption. It is this restoration of the divine image, entailing mystical knowledge, love and purification, which is the ultimate goal of all Christian asceticism. Though Athanasius' doctrine is here dependent upon Alexandrian Platonism, its main outlines are coherent and clear.

Athanasius' authentic works may be divided into four groups.

1. The dogmatic, controversial works, such as the *History of the Arians*, the *Discourses Against the Arians*, the *Treatise on the Synods of Rimini and Seleucia*, and various apologies written in the heat of controversy.

2. The letters, which are today perhaps the most interesting section of his works. These include the *Festal* (*Paschal*) *Letters*, written over the years 329–348 to exhort his flock on the occasion of the Lenten fast and the approach of Easter; four *Letters to Serapion* dealing especially with the divinity of the Holy Spirit, doctrinal letters *On the Teaching of Dionysius*, *On the Decrees of Nicaea* and several others dealing with the Incarnation. There are many more, including a number of official episcopal documents; to these should be added the *Letter to Paphnutius* preserved in a British museum papyrus which may be from Athanasius' own hand (*P. Jews* 1929, ed. by Bell).

3. The ascetic corpus includes the *Life of Antony;* a number of treatises *On Virginity* preserved in whole or in part, whose authenticity is still disputed; and the pseudo-Athanasian *Life of Syncletica*. The Greek treatise *On Virginity* (ed. by Von der Goltz, 1905), surely reflects Athanasian teaching, but its use of the term *hypostasis* in the sense of divine Person makes the attribution somewhat doubtful. There are fragments of other treatises on the subject in Coptic, Syriac and Armenian translations. Further, a Coptic ascetic epistle *On Love and Self-Control* may be authentic.

4. Of what must have been a considerable exegetical corpus there remains a short treatise *On the Interpretation of the Psalms* and some fragments of an allegorical exegesis of the psalms preserved in catenae.

Among the inauthentic works must be mentioned a sermon *On the Devil* along with other short pieces. The *Interpretation of the Creed* and *On the Unity of Christ* are recognized as inauthentic; and the 12 books of *De Trinitate* preserved in Latin, though derived in part from Athanasius, probably comprise five distinct works which originated in Italy or northern Africa toward the end of Athanasius' life and after his death. Finally, the so-called *Athanasian Creed*, the *Quicumque*, consisting of 40 rhythmic Latin *cola*, though attributed to Athanasius since the 7th century, undoubtedly comes from a later period. It is, again, a Latin work, and originated perhaps in the area of northern Italy or southern France; some have plausibly linked it with the school of Lerins, others with the Ambrosian chancery at Milan. In any case it represents orthodox Trinitarian doctrine of the post-Nicene period.

In connection with the Greek text of Athanasius, the critical work of H. G. Opitz, R. P. Casey and others has drawn attention to the various recensions which existed even in his authentic works, the result of competitive editorial activity by Athanasius' followers on the one side and by his enemies on the other.

ATHAPASKAN (Athabaskan), a large and widespread family of North American Indian languages which included, during the aboriginal period, 50 or more distinct idioms. More than half of these, the Northern Athapaskan languages, were spoken in the whole interior of Canada and Alaska northwest of the Churchill river. A second major division, Pacific Coast Athapaskan, included 16 languages spoken in southwestern Oregon and adjacent northern California, from the Umpqua river in Oregon to the head of the Eel in California. The third division, Southern Athapaskan or Apachean, contained only seven languages. These were spoken by the Navaho and six Apache tribes in Arizona, New Mexico, Texas and the Mexican states of Chihuahua and Coahuila.

This geographical classification is not entirely consistent with a strictly linguistic classification—only Pacific Coast Athapaskan and Apachean are both geographic and linguistic units. In the north there are at least seven linguistic subfamilies. Four of these—Tanaina, Koyukon, Ahtena and Ingalik—lie wholly within Alaska. The fifth, Kutchin-Han, occupies the territory on both sides of the northern half of the Alaskan-Canadian boundary. The sixth subfamily includes Tanana and Nabesna, spoken in Alaska south of the Kutchin-Han; Carrier, spoken in central British Columbia; and Hare-Dogrib, Slave and Chipewyan, which occupy a continuous area in northern Canada from the Mackenzie river to Hudson bay. Those of the seventh subfamily—the Beaver, Sarsi, Kaska and Sekani—live south of the Hare, Slave and Chipewyan and north of the Carrier. Finally there are a number of northern languages which cannot be classified for lack of sufficient data: Tutchone, Mountain, Tagish, Tahltan and Tsetsaut.

The Pacific coast subfamily includes Umpqua, Coquille, Galice, Applegate, Chasta Costa, Euchre Creek, Tututni and Chetco in Oregon, and Tolowa, Hupa, Mattole, Kato, Wailaki, Nongatl, Lassik and Sinkyone in California. There are seven Apache (*q.v.*) languages: Navaho, San Carlos, Chiricahua, Mescalero, Jicarilla, Lipan and Kiowa Apache.

The northern languages are more diverse than the Pacific coast group or the Apache. This means that the original Athapaskan homeland lay in the north and that both the Pacific coast peoples and the Apaches migrated southward from the Canadian-Alaskan region. Chronological studies indicate that the breakup of the original Athapaskan speech community began about 200 B.C. and that the movement southward began about four hundred years later. These short time periods help to account for the great similarity between the northern languages and those in the south. The difference between Kutchin and Navaho, for example, is little greater than that between English and German.

The Athapaskan languages differ markedly from most of the Indian languages spoken near them. There are, however, a number of features of similarity between Athapaskan, Tlingit, on the northern coast of British Columbia, and Haida, on Queen Charlotte Island. Edward Sapir in 1915 examined these similarities and concluded that all three groups were members of a single larger family called Nadene. Although detailed proof of his hypothesis has not been published, it is accepted by most of the scholars who have reviewed Sapir's data.

Athapaskan speech communities have always been small. The total population in the northern area, with its 25 or more tribes, never exceeded 30,000. European colonization reduced the Indian populations of the Americas and altered the language habits of the groups that survived. Thus, by mid-20th century, most of the Pacific Coast languages were either extinct or spoken only by a few older people. Only Hupa (*q.v.*) was still active and it had fewer than 200 speakers. Similar changes occurred in the north and among the Apaches but not to the same degree. Navaho (*q.v.*) had at that time the largest number of speakers (about 80,000) of any Athapaskan tongue but most of these spoke English as well. It is probable that most and perhaps all the Athapaskan languages will become extinct.

ATHEISM, the denial of "God" or of "the gods." As such, it is the opposite of theism (*q.v.*), which affirms the reality of the divine and seeks to demonstrate its existence. Atheism is to be distinguished from agnosticism (*q.v.*), which leaves open the question whether there is a god or not, professing to find the question unanswered or even unanswerable. For the atheist, the question has been answered, and in the negative: "There is no god."

To include all that is designated as atheism, it is necessary to distinguish between theoretical atheism and practical atheism. Theoretical atheism is the denial, in principle, that there is a god. Most often, the term is used polemically to label the position of an opponent who denies one's conception of the divine. Thus the Jews and the early Christians were accused of atheism by the Romans, despite the obvious theism of Jewish and Christian beliefs, because they refused to acknowledge the Roman gods, including the emperor, as truly divine. Orthodox Christians, on the other hand, employed the term atheist in their polemics against various heretics, notably against those who, while affirming the existence of God, denied the doctrine of the Trinity (*q.v.*). Thinkers like Spinoza (*q.v.*) earned the label because they seemed not to distinguish accurately enough between God and the world and thus appeared to deny the transcendence of the divine. From these examples it is evident that theoretical atheism in the absolute sense is not so common as the frequent use of the term might suggest. At the same time, it is not accurate to maintain, as some have, that there are no atheists. A thoroughgoing materialism or mechanism (*q.v.*) has led some to the flat declaration that there is no Being that deserves the title or the attributes of deity. If it is maintained that the universe is fully self-explanatory, this seems to be an atheistic philosophy. Similarly, a thoroughgoing humanism (*q.v.*) appears to require the adjective atheistic, for it asserts that man neither has nor needs the help of any Holy to which to turn in penitence, prayer or adoration. Nevertheless, the effort of certain modern philosophers to posit a "finite God" and the pantheism (*q.v.*) or panentheism of others tend to limit the applicability of the label "theoretical atheism" in modern thought.

Practical atheism, on the contrary, is not limited to the intelligentsia, but represents the working philosophy of large numbers of men. Practical atheism is the denial, in practice, that there is a god. For such a philosophy, the question of the existence of God is irrelevant to the meaning of life and the decisions of human existence. The discovery of scientific explanations for phenomena formerly attributed to supernatural causes has helped to bring about the "disenchanted world" of many modern men. Similarly, the elimination of the influence of organized religion from spheres of activity such as medicine, education and the arts has prompted men to construct for themselves a world view in which ideas of God and of a life after death play no significant

role. The term secularism was coined in the middle of the 19th century to identify such a philosophy of life. When pressed in a debate, its adherents may assert their belief in God, that is, their acceptance of the idea that there is a god. Apart from such debate, of course, they have no need for this hypothesis. Most theologians would claim that this is in fact atheism. For if the term god has any meaning, they would argue, that meaning must include the obligation of man to enter into significant relations with the divine, whatever form those relations may assume. As many observers have noted, however, "practical atheists" may still be deeply religious in their outlook on the universe, regarding with reverent awe both the processes of nature and the functioning of society. Even without the idea of divine sanction and law, they hold to their moral ideals with deep conviction and strive earnestly to live up to them. Thus they are ethical without being religious, or perhaps religious without having an explicit faith in God.

The presence of such an atheism, whether in its primitive or its modern forms, has compelled the revision of the very definition of religion to include nontheistic faiths such as Marxism, which elicit a religious loyalty from their faithful even as they deny the reality of divine Being. Meanwhile, both theists and agnostics (and perhaps even atheists) would agree that whatever God there is does not depend for his reality or sovereignty upon the efforts of theologians and philosophers to attack or defend his existence.

ATHEL, the name given to the tree *Tamarix aphylla* (*T. articulata*) of the Tamaricaceae. Originally a native of northeastern Africa and western Asia, it has become naturalized in several other parts of the world, including arid regions of southwestern United States, where it is well established. The tree, which resembles certain conifers, occasionally attains a height of 60 ft. and is readily distinguished by its jointed twigs with minute, ensheathing leaves and small sessile flowers borne in terminal panicles.

The bark is rich in tannin. Reproduction is accomplished equally well by seeds, cuttings or coppice. (E. S. HR.)

ATHELNEY, a slight eminence of small extent, formerly an island and now rising from the drained marshes about the junction of the rivers Tone and Parrett in Somerset, Eng. Early in 878 King Alfred, hard pressed by the Danish advance, took refuge amid the marshes of Somerset, constructing a stronghold at Athelney. Using this as a base he broke out to win a decisive victory at Edington, near Chippenham. The Danish king, Guthrum, sought terms and was received and baptized at Aller on the mainland opposite Athelney. Alfred founded a monastery on the island as a thank offering for his victory. The Alfred jewel, now in the Ashmolean museum, Oxford, was found at Athelney in 1693. It is an elaborate gold ornament with an enameled plaque covered with crystal and an inscription recording that it was made for the king (*see* JEWELRY). The story of Alfred minding the cakes for the mistress of the hut in which he was sheltered is credibly recorded as an illustration of the straits to which he was reduced; details, including his negligence in allowing them to burn, were later literary embellishments.

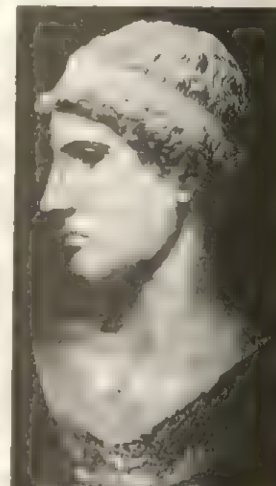
(C. A. R. R.)

ATHELSTAN: *see* AETHELSTAN.

ATHENA (ATHENE), the Greek city-protectress, goddess of war, handicraft and practical reason, identified by the Romans with Minerva (*q.v.*). The portrait of Athena found in poetry and art from Homer onward is accurate for her cult generally, largely because her activities were especially appreciated by the society of poets and artists. She was essentially urban and civilized, the antithesis in many respects of Artemis (*q.v.*), goddess of the outdoors.

When, during the 2nd millennium B.C., the Greeks settled the peninsula to which they later gave their name, they probably found Athena's worship already established, in Crete if not on the mainland. Her certainly non-Hellenic name apparently belongs to the language of the Greeks' predecessors. The pre-Greek Minoan Cretans, as M. P. Nilsson showed, worshiped a snake-goddess who protected the home and who, like other Minoan deities, was thought to appear among men in the shape of a bird; snake and bird attributes as well as bird epiphany are especially characteristic of Athena as she appears in Homer and afterward. The Minoans worshiped their goddess in recessed sanctuaries in homes and palaces, her priest being the master of the house or, in palaces, the king. The Greeks of the Mycenaean age at the end of the millennium included such sanctuaries in their palaces. Yet their economy, unlike that of the Minoans, was largely military, so that Athena, while retaining her domestic functions, became in answer to her worshipers' demands a goddess of war. The name Athena Potnia, "Lady Athena," has been read on one of the Mycenaean tablets, though unfortunately difficulties remain in the way of its complete acceptance. But archaeology confirms the continuity of her worship, for Athena's temples on the acropolises of Athens and Mycenae stand directly on the ruins of the Mycenaean palaces. The locale remained holy while later societies succeeded the Mycenaean, and doubtless owed its sanctity to the presence of the same goddess throughout the centuries.

Athena was very early associated with the acropolises of a number of other cities as well. This has led some to style her a "mountain mother" similar to the Asiatic Magna Mater and a Cretan goddess who is sometimes called the Mother of the Mountains (*see* ARTEMIS). But Athena's choice of the acropolis as a dwelling place more likely stems from the location there of the king's palace, while the theory that Athena was originally a mother-goddess depends upon a most unscientific generalization from a handful of exceptional references. She has no consort and, worse yet, no offspring, unless wild interpretations of one or two relatively late myths are accepted. She need not have been a virgin from the beginning, but the characteristic was very early acquired, and thus were her epithets Pallas and Parthenos ("Maiden," which exhibits the same ambiguity as the Greek words) generally interpreted.



ALINARI
HEAD OF ATHENA, PROBABLY A COPY OF THE LEMNIAN, IN THE MUSEO CIVICO, BOLOGNA, ITALY

The fifth Homeric hymn expressly states that Aphrodite cannot affect Athena, but the idea is older: for a war-goddess to accept domination, or a palace-goddess violation, seems intolerable. The old theory that she was a water-goddess and perhaps of Libyan origin rested largely on a doubtful interpretation of her epithet Tritogeneia ("Water-Born") and can be discarded with the same confidence with which the epithet can be declared unexplained. Ulrich von Wilamowitz' view that Athena was originally a shield-goddess has not found general acceptance, though his account of her later development is a masterful exposition.

In the *Iliad* Athena as war-goddess inspires and fights alongside the Greek heroes, notably Diomedes in his defeat of Ares in book v. To possess her aid is synonymous with military prowess and is not, as readers occasionally feel, considered an unfair advantage.

In the *Iliad* Zeus specifically assigns to Ares and Athena the sphere of war. Ares, the Trojan war-god, is generally pictured as delighting in blood lust and death. It is unsafe, however, to hold that in contrast Athena represents the noble and rational side of war; her moral and military superiority to Ares derives in part from the vastly greater variety and importance of her functions, in part from the patriotism of Homer's predecessors, Ares being of foreign origin. Athena proclaims her nationalism in book xxi of the *Iliad*, where she wishes that all who help the Trojans might be

vanquished as she has just vanquished Ares and Aphrodite: "So we should long ago have ceased from battle, having destroyed the strong-founded city of Ilium."

The qualities that lead to victory are found on the aegis (*q.v.*) Athena carries when she goes to war: fear, strife, defense and assault, but not reason or prudence. On it too is the Gorgon's head, terrifying indeed but scarcely remarkable for its acumen (*Iliad*, v).

As palace-goddess Athena was bound to preserve the sanctity of Menelaus' household, and the pre-Homeric tradition probably attributed her violent and apparently unreasonable hatred of everything Trojan to her anger at Paris's rape of Helen. The obscurity of the *Iliad* on this point may be due to a dimming awareness at that time of Athena's role as palace-goddess; later poetry supplied her motivation through the story of the judgment of Paris (*q.v.*).

The Minoan house-goddess would have been interested in the household arts, and such female skills are Athena's domain. She moves symbolically from domestic to bellicose role when, in book v of the *Iliad*, before donning the aegis, she removes a robe woven by her own hands. To say that a woman "rivalled Athena in handicrafts" (cf. *Iliad* ix, 390) was high praise.

Behind the moral problem of the *Odyssey*, the hero's restitution of his home, Athena the palace-guardian is faintly visible, but as tutelary deity of the king she presses Odysseus to assert his rights and rid his palace of Penelope's suitors; she likewise undertakes his son Telemachus' moral education. Somewhat surprisingly she bestows beauty—*charis*—upon her protégés, but since mankind generally fails to benefit from these attentions they must be ascribed to the manifold relation between herself and the royal family. Myths from later sources portray her similarly as helper of Perseus and Heracles, perhaps originally Mycenaean priest-kings, suggesting that her efforts were extended to all who held the office. Yet the kingship as such did not claim her protection; this charge fell upon the more remote Zeus. Athena, the "ever-near," in W. Otto's phrase, guarded rather the king's person, and in so doing became goddess of good counsel as well as war. The goddess of good counsel is found in the *Iliad* also; she prevents Achilles from carrying out his threat to Agamemnon and warns Odysseus against assaulting Sarpedon and his retinue.

In post-Mycenaean times the city, especially its citadel, replaced the palace as Athena's domain; the city-goddess has begun to emerge in book vi of the *Iliad*. Later epic poetry symbolized this role with the palladium (*q.v.*), an armed statue of Athena that Odysseus and Diomedes had to steal from Troy before the city could fall, and that several Greek cities later claimed to possess.

Athena was widely worshiped, but in modern times she is associated primarily with Athens, to which she gave her name. Her emergence there as city-goddess, Athena Polias, accompanied the transition from monarchy to democracy. She retained her association with birds, particularly the owl, which became famous as the city's own symbol. The snake continued to live in the Erechtheum, a temple of Athena Polias named after an early hero, Erechtheus. The *Odyssey* tells how Athena visited Erechtheus' house, and the scene is interpreted as the goddess's epiphanic descent to the Athenian priest-king, whose house may be the palace upon which the Old Temple on the Acropolis (perhaps an earlier Erechtheum) was built. More famous is the Parthenon, with its statue of Athena Parthenos and its pediments depicting Athena's birth and her contest with Poseidon for the suzerainty of the city. With each pediment frieze is connected a myth, neither satisfactorily explained. Hesiod, in the *Theogony*, tells how Athena sprang from Zeus's forehead, and Pindar adds that Hephaestus struck open his head with an ax. Pindar's version has been referred to the ritual of the Buphonia (*q.v.*), wherein an ox was sacrificed by splitting its skull. Others, reflecting that the Greek word *koruphe* means both "forehead" and "summit," have interpreted the myth as presupposing Athena's birth from mountain or acropolis. But birth from male limbs without female assistance is a common folk motif, perhaps adopted because Athena had no known or, in the light of her stature and independence, suitable mother. The contest between Athena and Poseidon on the west pediment featured her offer to the Athenians of the olive, his of the horse or a spring of water. As chief goddess Athena naturally supervised the economically vital olive culture, but the contest itself remains baffling. Theories hypothesizing a conflict between an invading Greek god, Poseidon, and the native goddess founder on the difficulty that the victors' god was defeated; Poseidon occupied a quite secondary role at Athens.

Erechtheus' alter ego, Erichthonius, was said to have instituted Athena's worship at Athens as well as her birthday festival, the Panathenaea (*q.v.*). The story that Athena entrusted the daughters of Cecrops with a chest containing the infant Erichthonius, and that for opening it in defiance of her command they were driven mad, is an etiological myth for another rite, the Arrephoria. Two maidens carried secret objects from Athena's temple on the Acropolis to the sanctuary of Aphrodite and returned similarly burdened; they may have borne snake symbols and, for Aphrodite's benefit, phalluses. The rite concerned the growth of vegetation, the sphere of Erichthonius and of the daughters of Cecrops, who were dew spirits. The similarly purposed Procharisteria celebrated the goddess's rising from the ground with the coming of spring. But Athena's connection with vegetation was an accidental by-product of her general civic duties.

ALINARI

PROMACHOS ("CHAMPION") ATHENA IN THE NATIONAL MUSEUM, ATHENS

Mythology made Erichthonius the issue of an abortive attempt by Hephaestus upon Athena's virginity, the seed impregnating the ground instead. Scholars as little impressed with her virtue as Hephaestus have seen behind this story another in which his desire was not frustrated, in which he was her consort. But Erichthonius, as a vegetative spirit, was probably always thought to be born of the earth or an earth-goddess such as Athena never was. Her relationship with Hephaestus derives from the similar functions of the smith-god and the goddess of industry, Athena Ergane ("Working," a very common epithet).

Two Athenians, Phidias and Aeschylus, contributed significantly to Athena's spiritual development. She inspired three of Phidias' masterpieces: the archaistic Promachos ("Champion"), in which her military character doubtless predominated; the Lemnian, where the maiden superseded the warrior; and the chryselephantine Parthenos, where the warrior, tempered by pensive majesty, was felt to represent perfectly the city-goddess. In Aeschylus' *Eumenides* she founds the Areopagus (*q.v.*), and by breaking a deadlock of the judges in favour of Orestes, the defendant, she sets the precedent that in Athenian jurisprudence a tied vote signified acquittal. As goddess of wisdom she pleads for justice tempered with reason and mercy, as against the blind vengeance demanded by the Furies. Though she and Zeus strive for the same end, she alone appears on the stage; symbolizing the city's striving toward this higher concept of justice, she still does not leave the realm of men. *See* NIKE; *see* also Index references under "Athena" in the Index volume.

ATHENAEUM, a name originally applied in ancient Greece to buildings dedicated to Athena, and specially used as the designation of a temple in Athens, where poets and men of learning were accustomed to meet and read their productions. The academy for the promotion of learning that the emperor Hadrian

built (about A.D. 135) at Rome, near the Forum, also was called the Athenaeum. Poets and orators still met and discussed there, but regular courses of instruction were given by a staff of professors in rhetoric, jurisprudence, grammar and philosophy. The institution, later called Schola Romana, continued in high repute until the 5th century. Similar academies were founded in the provinces and at Constantinople by the emperor Theodosius II. In modern times the name has been applied to various academies, as those of Lyons and Marseilles and the Dutch high schools; and it has become a very general designation for literary and scientific clubs, the most famous club of the name being that founded in London by Sir Walter Scott and Thomas Moore in 1824. In the United States the well-known Boston Athenaeum, founded in 1807, is the home of George Washington's library. The word is also familiar as the title of several literary periodicals, notably of the London weekly founded in 1828.

ATHENAEUS (fl. *c.* A.D. 200), Greek rhetorician and grammarian, whose *Deipnosophistai* is a storehouse of varied information, much of it drawn from works no longer extant, was born at Naucratis in Egypt. He himself states that he wrote a treatise on the *thratta*—a kind of fish—and a history of the Syrian kings, both now lost. The *Deipnosophistai* ("Authorities on banquets," not, as sometimes incorrectly translated, "Philosophers at dinner"), in 15 books, belongs to the genre of symposium literature of which Plato's *Symposium* is the first example. The first two books, and parts of the 3rd, 11th and 15th, are extant only in epitome, but the rest has survived complete.

It professes to be an account of a banquet held at the house of Laurentius, a scholar and wealthy patron of art. Among the guests are historical persons such as Galen the doctor and Ulpian the jurist. The conversation ranges from the dishes before the guests and information about food to literary matters of every description, including points of grammar and criticism, with remarks on music, song, dances, games and courtesans. The plan is clumsy, but the work is an invaluable repertory of fragments from nearly 800 writers.

The *Deipnosophistai* was edited by G. Kaibel in three volumes in the "Teubner Series" (1887–90) and by C. B. Gulick with an English translation in the "Loeb Series" in seven volumes (1927–41). The epitome was edited by S. P. Peppink in three volumes (1936–39).

See F. A. Wright, *History of Later Greek Literature*, pp. 283–288 (1932). (G. B. Kd.)

ATHENAGORAS (2nd century A.D.), Greek Christian Platonist who wrote an apology for the Christian religion, was an Athenian and probably taught in Alexandria. His apology, styled "embassy" (*Presbeia*), was addressed to the Roman emperors Marcus Aurelius and L. Aurelius Commodus between 176 and 180. It deals with the stock charges of atheism, cannibalism and incest or promiscuity alleged against the Christians, giving incidentally a survey of famous statues of Greek gods and one of the first statements on Christian sexual morality. In the earliest manuscript (dated 914) this work is followed by a treatise on resurrection (*Peri anastaseos*), also ascribed to Athenagoras, whose authenticity some modern speculation has questioned. It shows the same tenderness for Plato and the same use of Platonic terms as the apology, and the Christian doctrine of bodily resurrection for all (here grounded on arguments from the motive of creation, the nature of man and the need for rewards and punishments for body and soul in another life) is precisely the one that a Platonist would find most novel and provocative. Athenagoras' writing is clear and forcible, and he is a pioneer in the fashioning of technical terms for the concepts of Christian theology. *See* also Apologists, Early Christian.

Schwartz in *Texte und Untersuchungen*, vol. iv, part 2 (1891); Eng. trans. with introduction and commentary by J. H. Crehan (1956) in *Ancient Christian Writers*. *See* also J. Quasten, *Patrology*, vol. i (1950); R. M. Grant, "Athenagoras or Pseudo-Athenagoras," *Harvard Theological Review*, vol. xlvii (1954). (J. H. Cn.)

ATHENODORUS, an ancient Greek personal name, the bearers of which include two sculptors, two philosophers and a physician.

The Sculptors.—The earlier of the two sculptors was Athenodorus of Cleitor, who executed the statues of Apollo and Zeus which the Spartans dedicated at Delphi after their victory at Aegospotami (405 B.C.) in the Peloponnesian War. The second was Athenodorus of Rhodes, who collaborated with his father Agesander, on the celebrated Laocoon group (*see* Greek Art).

The Philosophers.—Athenodorus Cordylion (1st century B.C.), a Stoic, born at Tarsus in Cilicia, became keeper of the library in Pergamum but finally settled in Rome, where he died, an old man, in the house of the younger M. Porcius Cato.

Athenodorus Cananites (also called Athenodorus son of Sandon; *c.* 74 B.C.–*c.* A.D. 7), also a Stoic, was born at Canana, near Tarsus. After studying under Poseidonius in Rhodes, he went to Apollonia in Illyria, where the young Octavian (afterward the emperor Augustus) was his pupil. Athenodorus acquired a lasting influence over Octavian and followed him to Rome in 44 B.C., but was later allowed to return to Tarsus to remodel the city's constitution. There he succeeded (*c.* 15–10 B.C.) in setting up a government of property owners in the Roman interest. Strabo, a friend of his, and Cicero, whom he helped in the composition of the *De Officiis*, provide the main sources of information about him, as none of his writings are extant. Strabo describes him as a learned scientist. Sir William Ramsay, in an article in the *Expositor* (Sept. 1906), suggested that the influence of Athenodorus may account for the resemblances discernible between St. Paul and the younger Seneca, as St. Paul can hardly not have known his doctrine.

The Physician.—Another Athenodorus (1st century A.D.) was the author of a work *On Epidemics*.

ATHENRY (Baile Átha an Ríogh), a market town of County Galway, Republic of Ireland, lies on the river Clarin, 15 mi. E. of Galway by road. Pop. (1956) 1,287. Its Gaelic name means "the town of the king's ford" and after the Anglo-Norman invasion it grew to importance as the first town of the De Burghs and De Berminghams. There are remains of walls erected in 1211 and of a castle of 1238. A Dominican monastery was founded by Myler de Bermingham in 1241 and repaired in 1893. Of the Franciscan monastery of 1464 little is left. The town returned two members to the Irish parliament from the time of Richard II to the Union; but it never recovered from the wars of the Tudor period during which it was successfully besieged by "Red" Hugh Roe O'Donnell in 1596.

ATHENS (Lat. Athenae; mod. Gr. Athinai; modern colloquial Greek Athena), the capital of the kingdom of Greece and of the nome (department) of Attica, lies toward the southern end of the central and principal plain of Attica (*q.v.*). It is the political, economic and cultural centre of Greece. There have been various theories with regard to the origin of the name, which is now held to be derived from the patron goddess Athena, whose name, like others with the same ending, is thought to be pre-Hellenic.

This article is divided into the following sections and subsections:

I. TOPOGRAPHY AND ANTIQUITIES

The Attic plain slopes gently toward the coast of the Saronic gulf on the southwest; on the east it is overlooked by Mt. Hymettus (*q.v.*; 3,369 ft.); on the northeast by Mt. Pentelikon (*q.v.*; 3,638 ft.) (Pentelicus); on the northwest by Mt. Parnes (Parnis) (4,636 ft.); and on the west by Mt. Aegaleos (Aigaleos) (1,534 ft.), which descends abruptly to the bay of Salamis. In the centre a ridge, now known as Turcovuni, runs from northeast to southwest and culminates in the sharply pointed Mt. Lycabettus (1,112 ft.), the most prominent feature in the Athenian landscape, which directly overhung the ancient city but was not included in its walls. This range separates the valleys of the Cephisus (Kifissos) and Ilissus (Elisson) rivers. The former, rising in Mt. Pentelicus, enters the sea at Phaleron (Faliron), but in summer dwindles to an insignificant stream. The latter, coming from Mt. Hymettus, skirts the city on the southwest and is now usually dry owing to denudation caused by the destruction of the forests. Separated from Mt. Lycabettus by a depression to the southwest, through which flows a brook (probably the Eridanus river), stands the remarkable oblong rocky mass of the Acropolis (512 ft.), rising precipitously on all sides except the western; it served as a fortress and also as the sacred sanctuary of its tutelary goddess, Athena (*see* below). Close to the Acropolis on the west is the lower rock (370 ft.) of the Areopagus (*q.v.*), the seat of the famous council. Farther west are three elevations: to the northwest the so-called "Hill of the Nymphs" (348 ft.), on which the modern observatory stands; to the west the Pnyx (351 ft.); and to the southwest the loftier hill known as the Mouseion or Museum hill (482 ft.). A cavity to the west of the observatory is supposed to be the ancient barathron or place of execution. The distance from the Acropolis to the nearest point of the seacoast at Phaleron is a little more than three miles.

1. Influence of the Geographical Position.—The situation of Athens naturally favoured the growth of a powerful community. The Attic plain, notwithstanding the lightness of the soil, furnished an adequate supply of cereals; olive and fig groves and vineyards were cultivated from the earliest times, and pasturage for sheep and goats was abundant. The surrounding mountains are broken toward the northeast by an opening between Mt. Hymettus and Mt. Pentelicus toward Marathon, and are traversed by the passes of Decelea, Phyle and Daphne on the north and northwest, but the distance between these and the city was sufficient to obviate the danger of surprise by an invading land force. On the other hand Athens was sufficiently far from the sea to enjoy security against the sudden descent of a hostile fleet. Yet the three natural harbours, the ancient Piraeus (Piraievs or Peiraicus), Zea (Kea) and Munychia, favoured maritime commerce and the sea power which formed the basis of Athenian hegemony. The climate is temperate but liable to sudden changes; the mean temperature is 63.1° F., the maximum (in July) 99.01°, the minimum (in January) 31.55°. The clear, bracing air, according to ancient writers, fostered the intellectual and aesthetic character of the people and endowed them with mental and physical energy. For the architectural adornment of the city the finest building material was procurable in abundance; Mt. Pentelicus forms a mass of white, blue-veined marble; another variety, somewhat similar but generally of a bluer hue, was obtained from Hymettus. For ordinary purposes gray limestone from Lycabettus and the adjoining hills, limestone (the so-called poros stone) from the promontory of Acte (Akti) and conglomerate were largely employed. For the ceramic art admirable material was at hand in the district northwest of the Acropolis. The water supply then, as now, being insufficient for a large and growing city, was supplemented by an aqueduct constructed in the time of the Pisistratids and by others of the Roman period. A great number of wells were also sunk and rain water was stored in cisterns.

2. Sources for Athenian Topography.—First in importance for the purpose of scientific topography is the evidence of the natural features of Attica and the architectural remains; to these may be added the testimony of inscriptions often of decisive importance. Next comes the evidence derived from ancient literature and especially from descriptions of the city or its different localities. The earliest known description of Athens was that of Diodorus of Athens (4th century B.C.). Among his successors were Polemon of Ilium (2nd century B.C.), who gives a minute account of the votive offerings on the Acropolis and the tombs on the Sacred way, and Heliodorus (probably of the 2nd century B.C.), who wrote 15 volumes on the monuments of Athens. Of these and other works of the earliest topographers only some fragments remain. About A.D. 150 Pausanias (*q.v.*) visited Athens at a time when the monuments of the great age were still in their perfection and the principal embellishments of the Roman period had already been completed. The first 30 chapters of his invaluable *Description of Greece* are devoted to Athens, its ports and environs. His account, based mainly on personal observation, possesses an especial value because of his method of describing each object in the order in which he saw it during his walks. The literature of succeeding centuries furnishes only isolated references. Pausanias' accuracy was remarkably vindicated in the 20th century by excavations at Athens and elsewhere.

The notices of Athens during the earlier middle ages are scanty in the extreme. In 1395 Niccolo da Martoni, a pilgrim to the Holy Land, visited Athens and wrote a description of a portion of the city. Of the work of Cyriacus of Ancona, written about 1450, only some fragments remain, which are well supplemented by the contemporaneous description of the capable observer known as "Anonymus of Milan." Two treatises in Greek by unknown writers belong to the same period. The Dutchman Johannes Meursius (1579–1639) wrote three disquisitions on Athenian topography. The conquest by Venice in 1687 led to the publication of several works in that city, including the descriptions of R. de la Rue and Francesco Fanelli and the maps of Vincenzo Maria Coronelli and others. Systematic study was begun in the 17th century by French residents at Athens, the consuls J. Giraud and F. Chataignier and the Capuchin monks. The visit of the French physician Jacques Spon and the Englishman Sir George Wheler (or Wheeler) (1650–1723), fortunately took place before the partial destruction of the Parthenon in 1687; Spon's *Voyage d'Italie, de Dalmatie, de Grèce et du Levant*, which contained the first scientific description of the ruins of Athens, appeared in 1678; Wheler's *Journey into Greece* in 1682. A period of British activity in research followed in the 18th century. The monumental work of James Stuart and Nicholas Revett, who spent three years at Athens (1751–54), is still indispensable, owing to the demolition of ancient buildings which began about the middle of the 18th century. To this period also belong the labours of Richard Pococke and Richard Dalton, Richard Chandler, E. D. Clarke and Edward Dodwell. The great work of W. M. Leake (*Topography of Athens and the Demi*, 2nd ed., 1841) brought the descriptive literature to an end and inaugurated the period of modern scientific research.

3. Scientific Research.—Since the mid-19th century, excavations by the Greek archaeological service and by foreign archaeological schools, not to mention accidental discoveries during building operations in the modern town, have transformed our knowledge of the ancient city. At first Athenian topography became a speciality of German scholars, chief among them Wilhelm Dörpfeld, but after World War I members of the American School of Classical Studies began to work on the Acropolis and in 1931 the school began its momentous excavation of the agora (*q.v.*); the painstaking campaign, financed by the Rockefeller foundation, Marshall Aid funds, the Greek government and others, not completed until 1960, was in many ways the most remarkable achieve-

ment of archaeology in Greece. (For explanation of the architectural terms used below *see* GREEK ARCHITECTURE.)

4. Prehistoric Athens.—The natural advantages of the Acropolis were exploited from the earliest times. Remains of the Neolithic period are succeeded by plentiful traces of Early and Middle Bronze Age habitation and in the Late Bronze Age the rock was fortified, like the citadels of Mycenae and Tiryns. A Cyclopean wall ran around the natural edge of the rock, best preserved behind the temple of Nike and east of the Erechtheum (*q.v.*) where a postern gate gave access to the royal palace; two column bases of the palace hall were discovered in the foundations of the old temple of Athena nearby. West of the Erechtheum a staircase led down to an underground reservoir in the north face to provide a water supply in time of siege. The western approach to the Acropolis was further protected by a complex of walls called Enneapulon, "Nine-Gate" wall, but no certain traces survive. It seems probable, however, that it extended some way round the flanks of the rock to enclose the spring Clepsydra to the north or others unnamed to the south, and perhaps to give some protection to the clusters of dwelling houses on the north slope. Tradition ascribed the construction of this and the circuit wall to pre-Hellenic Pelasgians (*q.v.*), but later Athenians used the name Pelargicum to describe only the area once covered by Enneapulon, an area in their day thought to be under a curse. The apparent connection between the name and the reputed builders of the walls has caused much confusion, but the confusion is largely etymological and mythological and need not be discussed here.

The only substantial traces of prehistoric (chiefly Mycenaean) houses so far discovered are on the northern slope of the Acropolis, but tombs and other remains have been found in the Ceramicus, the agora, by the Hill of the Nymphs and elsewhere, the most notable being a series of Mycenaean rock-cut chamber tombs on the northern slope of the Areopagus. All this makes it clear that in the last phase of the Bronze Age Athens was a settlement of some wealth and importance.

5. The Dark Age.—Athens survived the Dorian invasion and as a result her culture developed without a break through the sub-Mycenaean, proto-Geometric and Geometric periods (*c.* 1200–700 B.C.). The rich pottery finds from tombs in the outer Ceramicus, already apparently the chief cemetery, give a clear picture of the poverty which followed the collapse of the Mycenaean world and of the gradual return to prosperity in the following centuries, a return accompanied by the development of a pottery style which by the 8th century was well in advance of anything else in Greece: Athenian Geometric (*see* GREEK ART). Of the city itself little or nothing is known. On the Acropolis there would have been, no doubt, a primitive temple to Athena Polias (Athena as protector of the city) and to Erechtheus (Homer *Odyssey* vii, 81), but no solid traces survive. The northern slope was still a residential area, as was the Areopagus, on the northwestern slope of which a complete house of the Geometric period has been excavated. Negatively, the rich harvest of tombs from the agora area shows that this was not yet set aside as a public place.

6. Archaic Athens.—By about 560 B.C. the city had taken on its classical shape. There was no doubt a circuit wall (Thucydides vi, 57, 1), although its course cannot now be traced, from the gates of which the roads from the country converged on the Acropolis. On the west side of the agora, by then established as the centre of civic life, the excavators uncovered an early 6th-century building, which they plausibly identify as the headquarters of the Solonian council (*see* SOLON), and a small temple of Apollo Patrous ("Ancestral Apollo") of similar date. A few hundred yards away, on the hill from which it took its name, sat the rival aristocratic council, the Areopagus, but no traces survive and only a small cleft in the northeastern face marks the site of the sanctuary of the Eumenides (*q.v.*), so memorably associated by Aeschylus with the foundation of the council.

The reign of Pisistratus and his sons (*c.* 560–510 B.C.) transformed the city. In the agora the council's quarters were greatly enlarged and remodeled and on the south side a large building was erected, perhaps to serve as a meeting place for Solon's popular court of appeal, the Heliaea. The water supply was improved by the construction of the southeastern fountain house in the agora and of another east of the Pnyx—the first supplied by a pipe running along the north slope of the Acropolis, from a source as yet unknown, the other by a tiled conduit connected with a stone aqueduct which came from the upper Ilissus river past the southern slope of the Acropolis. Outside the Dipylon gate the Academy, later the School of Plato, was laid out as a gymnasium. The gods, too, received their due: near the agora fountain house was built the Eleusinium, an urban branch of the great sanctuary of Demeter and Kore (Persephone) at Eleusis (*q.v.*); Pisistratus, the tyrant's grandson, celebrated his archonship in 522–521 B.C. by constructing an altar to the Twelve Gods, now hidden under the railway which cuts across the north side of the agora but securely identified by a corner of its surrounding fence which projects into the excavated area and by which was found a dedication to these deities; work was begun on a gigantic dipteral temple to Olympian Zeus southeast of the Acropolis, work which was interrupted by the fall of the tyranny and only resumed, on a different plan, in 174 B.C. (*see* below); another shrine in the same area received a new altar from Pisistratus the younger to commemorate his archonship; and about the same time his father, Hippias, completed the building of a new and splendid temple to Athena Polias on the Acropolis, the Early or so-called Old Temple, between the later sites of the Parthenon and Erechtheum.

This Pisistratean building program introduces two topographical problems of long standing and some importance: (1) Pausanias (i, 14, 1) says that the fountain Enneacrunus ("the fountain of the nine spouts") was embellished by Pisistratus. He places it firmly in the agora, near the Eleusinium; in other words he is almost certainly speaking of the southeastern fountain house mentioned above. On the other hand Thucydides, in a passage of great importance for Athenian topography (ii, 15), puts Enneacrunus, which he says was also called Callirrhoe, just as firmly to the south of the Acropolis together with the sanctuaries of Zeus Olympius, Apollo Pythius, Ge and "Dionysus in the Marshes"; the last two cannot be certainly identified but both may be near the theatre of Dionysus; the first two are firmly fixed near the north bank of the Ilissus and by an apparently happy chance there is a fountain on its opposite bank, called to this day Callirrhoe. Alternatively with a liberal interpretation of Thucydides Enneacrunus might be found in the fountain house east of the Pnyx, near which Dorpfeld found what he claimed to be the appropriate sanctuary of Dionysus. In either case there is a conflict between Pausanias and Thucydides. Some scholars would alter Thucydides' text to read "to the north of the Acropolis" and proceed to reduplicate sanctuaries of Zeus, etc., on the north slope, but this drastic solution fails to convince and there remains a choice between the authority of Thucydides and that of the conscientious but fallible traveler of the 2nd century A.D.

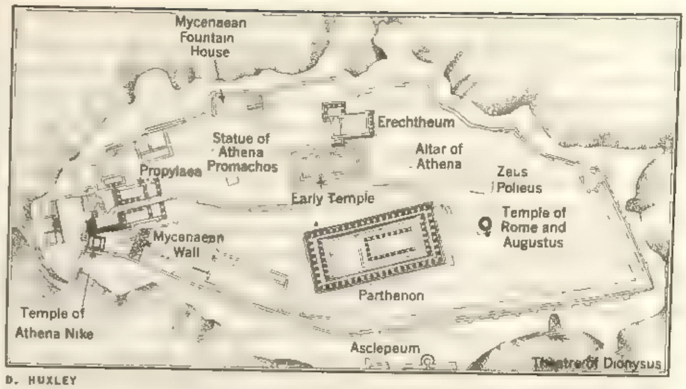
(2) It is impossible here to do more than hint at the problems which surround the history of the early temples on the Acropolis. The archaeological elements are three: (*a*) the foundations of the Old Temple and some fragments of its architectural members (of about 520 B.C.); (*b*) the foundations of an earlier temple, begun about 490 B.C. but never completed, on the site of the Parthenon; and (*c*) some fragments of pedimental sculpture of the first half of the 6th century, on a scale which indicated that they must have belonged to a substantial building. Most scholars accept in some form the following economical and attractive solution. Certain peculiarities in the construction of (*a*) suggest that the inner part once stood alone as a simple cella, distyle in antis; to this early structure the sculpture could be fitted. The Pisistratids would then have added the imposing colonnade round it and after the institution in 508 B.C. of the new democracy the construction of a yet more impressive building on an entirely new site would have begun. But according to an American architect, W. B. Dinsmoor the whole of the Old Temple is Pisistratean and to accommodate the sculpture he postulates an even earlier structure on the Parthenon site, "the grandfather" of the Parthenon. This grandfather left no trace on the ground but according to Dinsmoor bequeathed his name to his successors. This name, the Hecatompedon or "Hundred-footer," has usually been thought to belong to the Old

Temple in its earlier form (the measurements are approximately correct) and to have been transferred thence to the Parthenon, of which the cella proper is of similar length. Dinsmoor prefers to restrict the name to one site and would have it first applied to the earliest Parthenon. Many of Dinsmoor's arguments are weak (especially those for the unity of the Old Temple) but the problem was still far from final solution in the 1960s.

7. Classical Period.—The almost complete destruction of the buildings on the Acropolis and in the city in the Persian invasion of 480 B.C., among them many shrines which religious sentiment might have preserved, facilitated the magnificent architectural designs of Themistocles, Cimon and Pericles (*qq.v.*), while the rapid growth of the Athenian empire provided the necessary means for their execution. After the departure of the Persians the first necessity was the reconstruction of the defenses. The walls, then built under the direction of Themistocles, embraced a larger area than the previous circuit, with which they coincided at the Dipylon gate on the northwest where the Sacred way to Eleusis was joined by the carriage route to the Piraeus and roads to the Academy and Colonus. The other important gates were the Piraic and Melitan on the west; the Itonian on the south leading to Phaleron; the Diomean and Diocharean on the east; and the Acharnian on the north. The wall, strengthened with numerous towers, enclosed the quarters of Collytus on the north, Melite on the west, Limnae on the southwest and south and Diomea on the east. By mid-20th century the remains had not been systematically excavated except near the Dipylon; sepulchral monuments built into the masonry illustrate the statement of Thucydides with regard to the employment of such material in the hasty construction. The circuit has been ascertained in its general lines; it is given by Thucydides (ii, 13, 7) as 43 stades (about $5\frac{1}{2}$ m.), exclusive of the portion between the points of junction with the long walls to the Piraeus, but the whole circumference cannot have exceeded 37 stades.

8. The "Long Walls."—The design of connecting Athens with the Piraeus by long parallel walls is ascribed by Plutarch to Themistocles. Of these the north and Phaleric walls were actually built between 461 and 456 B.C. in the early years of the administration of Pericles; the middle wall may be as late as 444–442 B.C. The north wall, leaving the city near the modern observatory, ran from northeast to southwest near the present road to the Piraeus until it reached the Piraeus walls a little to the east of their northernmost bend. The middle wall, beginning south of Museum hill, gradually approached the northern wall and, following a parallel course at an interval of 550 ft., diverged to the east near the modern New Phaleron and joined the Piraeus walls on Munychia where they turn inland from the sea. The course of the Phaleric wall has been much disputed, but it must have left the city wall near Museum hill and then have run either directly to the eastern corner of Phaleron bay or in a rough semicircular sweep to rejoin the middle wall near the defenses of the Piraeus. It may have been abandoned toward the end of the Peloponnesian War; it was certainly destroyed with the others in 404 B.C. and was not rebuilt by Conon in 393. The parallel walls fell into decay during the Hellenistic period and were finally demolished by Sulla. For a detailed account of the Piraeus and its fortifications which completed the defensive system of Athens, see PEIRAEEUS.

9. The Acropolis.—The "Pelasgian" fortifications of the Acropolis were destroyed by the Persians and all its major monuments razed or severely damaged. Soon after their departure the existing north wall was hastily erected with many fragments from the sack built into it. The fine walls on the south and east were built by Cimon after the victory of Eurymedon, 468 B.C.; they extend considerably beyond the prehistoric circuit, the intervening space being filled up with the debris of the ruined buildings so as to increase the level space, an operation which produced a priceless collection of archaic statuary and vases. Cimon also completed the wall on the north side at both ends and added to its height; the ground behind was leveled up on this side also, the platform of the Acropolis thus receiving its present shape and dimensions. At the southwestern corner, on the right of the old entrance, an early bastion was encased in a rectangular projection which formed



D. HUXLEY

PLAN OF THE ACROPOLIS, ATHENS

a base for the temple of Nike.

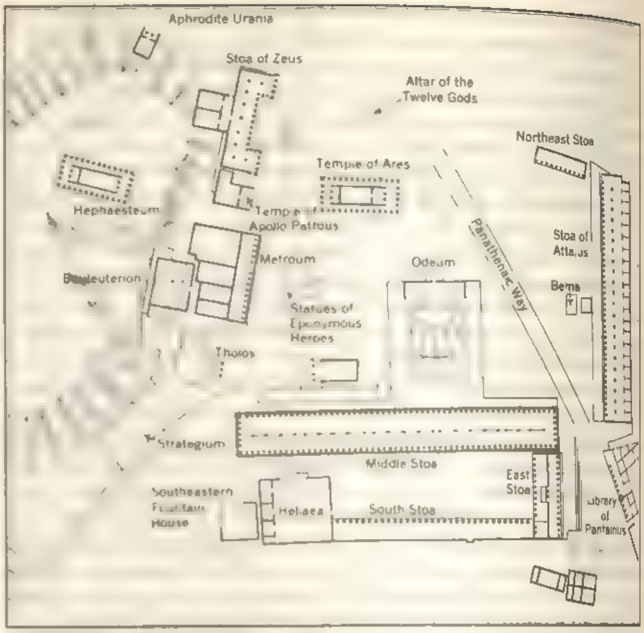
The greater monuments of the classical epoch on the Acropolis are described in separate articles. (*See* PARTHENON; ERECHTHEUM; PROPYLAEA.) Next in interest to these is the beautiful little temple of Athena Nike, wrongly designated "Nike Apteros" (Wingless Victory), standing on the bastion mentioned; it was begun in 449 B.C. and was probably finished toward the end of the Archidamian War (421 B.C.). The temple, which is entirely of Pentelic marble, is amphiprostyle tetrastyle, with fluted Ionic columns, resting on a stylobate of three steps; its length is 27 ft., its breadth $18\frac{1}{2}$ ft. and its total height, from the apex of the pediment to the bottom of the steps, 23 ft. The frieze represents on the east a number of deities; on the north and south Greeks fighting with Persians and on the west Greeks fighting with Greeks. Before the east front was the altar, beneath which an earlier altar has been found. The irregularly shaped precinct was enclosed by a parapet about 3 ft. 2 in. in height, decorated on the outside with beautiful reliefs representing winged victories engaged in the worship of Athena. The temple was still standing in 1676; some eight years later it was demolished by the Turks and its stones built into a bastion; on the removal of the bastion in 1835 the temple was reconstructed faultily by L. Ross, but was dismantled and more accurately rebuilt between 1935 and 1940. At either corner of the Propylaea entrance were equestrian statues dedicated by the Athenian knights; the bases with inscriptions have been recovered. From the Propylaea a passage led eastward along the north side of the Parthenon; facing the entrance was the colossal bronze statue of Athena Promachos by Phidias (*q.v.*), a dedication from the spoils of the Persian War. The statue, 30 ft. high, represented the goddess fully armed; the gleam of her helmet and spear could be seen by the mariners approaching from Sunium (Pausanias i, 28, 2). On both sides were numerous statues, one of Athena Hygeia (whose altar lies at the southeast angle of the Propylaea), set up by Pericles to commemorate the recovery of a slave injured during the building of the Parthenon; a colossal bronze image of the wooden horse of Troy; and Myron's group of Marsyas and Athena. Another statue by Myron, the Perseus, stood near the precinct of Artemis Brauronia, lying between the southeastern corner of the Propylaea and the wall of Cimon. Adjoining it to the east was a large rectangular building, which was apparently fronted by a colonnade; this has been identified with the *Chalcothece*, a storehouse of bronze implements and arms. Beyond the Parthenon, a little to the northeast, was the great altar of Athena, and near it the statue and altar of Zeus Polieus. Immediately west of the Erechtheum is the Pandroseum or *temenos* of Pandrosos, the daughter of Cecrops, seen there by Pausanias (i, 27, 2). This precinct, in which the sacred olive tree of Athena grew, was fixed by an inscription. Between it and the Propylaea were a number of statues, among them the heifer of Myron and perhaps his Erechtheus, the Lemnian Athena of Phidias and his effigy of his friend Pericles.

10. The Dipylon and Ceramicus.—The Ceramicus ("Potters' quarter") gives the best opportunities for studying both the cemeteries and the walls of Athens. The latter divide the region into the inner and outer Ceramicus and three stages are clearly seen:

the wall of Themistocles, the restoration by Conon in 393 B.C. and a reconstruction by Lycurgus (*c.* 396–325 B.C.; *q.v.*) some 60 years later. The Dipylon gate belongs to the last stage and consists of an inner and outer double gate separated by a rectangular court and flanked by towers on either side. Immediately to the south lay the Pompeum, built in the 4th century B.C. to serve as an assembly point for the Eleusinian and Panathenaic processions but noted also as a haunt of philosophers. Destroyed by Sulla in 86 B.C., it was later reconstructed on a different plan, probably in the time of Hadrian. South again lay the Sacred gate, the starting point of the Sacred way to Eleusis and at the same time an exit for the brook called Eridanus. Outside were tombs of every period, private and (from 464 B.C.) public. Inside lay the real commercial centre of Athens—crowded streets of shops and colonnades, cut by two main roads; the Panathenaic way, the route of Athena's great procession, which started from the Dipylon, passed the altar of the Twelve Gods and crossed the agora to mount the col between the Acropolis and Areopagus; and a continuation of the Sacred way, which skirted the small sanctuaries of Aphrodite Urania and of the People and of the Graces at the northern tip of the hill called Colonus Agoraeus and so entered the agora at its northwest corner.

11. The Theseum.—On Colonus, dominating the whole agora, stood the temple of Hephaestus and Athena as patroness of the arts and crafts. Its style indicates that this, the best preserved Greek temple in the world, is slightly older than the Parthenon (*i.e.*, *c.* 450–440 B.C.), and the unknown architect may even have changed his plan for the interior after seeing Ictinus' designs for the Parthenon. It has been known as the Theseum since the middle ages, apparently because some of its sculptures represent the exploits of Theseus, but its identification with the temple of Hephaestus seen by Pausanias (i, 14; 6) is practically certain. The temple is a Doric peripteral hexastyle in antis, with 13 columns at the sides; its length is 104 ft., its breadth 45½ ft., its height, to the top of the pediment, 33 ft. Some fragments of the east pedimental sculpture have been discovered, enough to recover the theme, the apotheosis of Heracles. The frieze contains sculptures only in the metopes of the east front and in those of the sides immediately adjoining it; the frontal metopes represent the labours of Heracles, the lateral the exploits of Theseus. As in the Parthenon, there is a sculptured frieze above the exterior of the cella walls; this, however, extends over the east and west fronts only and the east ends of the sides. The eastern represents a battle scene with seated deities on either hand, the western a *kentauromachia* (battle of centaurs). The temple is of Pentelic marble, except the foundations and lowest step of the stylobate, which are of Piraic stone, and the frieze of the cella, which is in Parian marble. The preservation of the temple is due to its conversion into a church in the middle ages.

12. The Agora.—Immediately beyond the entrance to the agora (or central market place) from the Sacred way could be seen the altar of the Twelve Gods. Beyond it and slightly to the north, beneath the modern railway, was the *Stoa poikile* (the "Painted portico"), the earliest of the stoas (*c.* 460 B.C.), which later enclosed the open space on all four sides. It took its name "painted" from the battle scenes which were hung around its walls, the work of Polygnotus (*q.v.*) and other noted artists, and gave its name, in part, to the Stoic school of philosophy founded by Zeno (*q.v.*), who practised there *c.* 300 B.C. The open space was dotted with statues, clustering most thickly along each side of the Panathenaic way, most notable among them those of the tyrannicides, Harmodius and Aristogiton, who in 514 B.C. killed Hipparchus, son of Pisistratus. This group was the work of Critius and Nesiotes (*q.v.*), a replacement of the earlier work of Antenor which the Persians had carried off in 480 and which was returned to the agora by Alexander the Great. Southward along the street which skirted the west side was first of all the Stoa of Zeus, built toward the end of the 5th century to replace an older shrine. This stoa was in the form of a colonnade with, a rare feature, two projecting wings between which stood an altar to the god. Pausanias' account (i, 14, 6) suggests that it may also have been known as the *Stoa Basileios* or Royal stoa, the seat of the



D. HUXLEY

PLAN OF THE AGORA, ATHENS

court of the archon basileus (*see* ARCHON), where the revised law codes of Solon and Draco (*qq.v.*) were displayed at the end of the 5th century; but some scholars reject this identification and postulate another stoa beneath the railway to the north. Next was the tiny temple of Zeus Phratrius and Athena Phratria (*c.* 350 B.C.) and the temple of Apollo Patrous, a limestone structure, tetrastyle in antis, of about 330 B.C. Together these deities presided over the tribal past of Athens—Apollo as the ultimate ancestor of the Ionians (*q.v.*), the others as patrons of the gentilitial association known as phratries. At Apollo's temple all citizens were registered and to him the magistrates swore their oaths on entering office. After a gap, giving access to the Hephaesteum (temple of Hephaestus) above, stood the complex of buildings which housed the chief administrative offices of Athens. Early in the history of the new democracy (*c.* 500 B.C.) a new and more splendid meeting place for the council (boule; *q.v.*) was built on top of Solon's tiny rooms, and some years later (*c.* 470 B.C.) came a replacement for Pisistratus' additions. This was the Tholos, a simple circular structure some 60 ft. in diameter, the roof supported on six interior columns, designed as living quarters for the standing committee of the council, the fifty prytanes. By about 400 B.C. the accumulation of state papers in the council house left no room for the councilors and another meeting room (the *bouleuterion*) was constructed at the rear, to which a covered approach and portico were added in the great building program of the time of Lycurgus the orator, carried out from 338–326 B.C.

Alongside the roadway on the east ran a great stone-lined drain of about 500 B.C. carrying rain water from the Areopagus northward to the channel of the Eridanus. Beyond this, and opposite the council house, was a small oblong enclosure surrounding a base on which were set statues of the eponymous heroes of the ten post-Cleisthenic tribes (*see* CLEISTHENES); the sides of the base served as an official notice board. A little farther south beyond the Tholos, both road and drain divided and there was a stone pillar carrying the words "I am the *horos* (the 'boundary stone') of the agora." Straight ahead and to the left were the Pisistratean fountain house and Heliaea, the gap between them filled by the rather shoddy South stoa of the late 5th century, a long two-aisled colonnade fronting a row of small rooms, probably designed to shelter the numerous courts into which the Heliaea was now divided; in the extreme southeast corner, at the side of the Panathenaic way, lay a small 5th-century building which the excavators plausibly identify with the *Argyrokopeion* (the mint). A branch left the road immediately after the *horos*, leading past a structure which probably served as the *strategeion*, headquarters of the strategoi (*see* STRATEGUS), toward the Hill of the Nymphs;

the main road carried on round the west end of the Areopagus with a branch mounting from there to the Pnyx.

In the 6th century the popular assembly had met in the agora, but Cleisthenes' democracy of 508 B.C. soon had to construct for itself a quieter meeting place on the gentle northeast slope of the Pnyx. In the first period use was made of the natural theatre-like shape of the hillside and the speaker faced up the hill toward his audience; toward the end of the 5th century the arrangement was reversed: the speaker stood on a bema or rostrum above the front rows of his audience while artificial terracing raised the outer edge of the semicircular auditorium to a slightly higher level. Somewhat less than a century later, again perhaps on the initiative of Lycurgus, the whole structure was extended and improved to produce the impressive form which can still be seen on the ground. The bema, a cube of rock, stood in front of two walls cut from the solid rock which met at an angle of about 158°. The ends of these were then connected by a semicircular retaining wall on a radius of approximately 70 yd. Immediately above the bema was an altar and behind it two stoas backing on the city wall which at this point ran along the crest of the hill.

13. The Dionysiac Theatre and Asclepeum.—The Dionysiac theatre, situated beneath the south side of the Acropolis, was partly hollowed out from its declivity. The representation of plays was transferred there from an original orchestra in the agora by the beginning of the 5th century B.C.; it afterwards superseded the Pynx as the meeting place of the assembly. There the first structures were provisional and of wood, and traces were found of the early orchestra and auditorium which had its seats in straight lines. This was replaced by a stone theatre during the administration of Lycurgus but the present arrangement of stage and orchestra date from Roman times. The stage building consisted of a rectangular hall with square projections on either side; in front of this was built in late Greek or early Roman times a stage with a row of columns which intruded upon the orchestra space. A later and larger stage, dating from the time of Nero, advanced still farther into the orchestra, and this was finally faced (probably in the 3rd century A.D.) by the bema of Phaedrus, a platform wall decorated with earlier reliefs, cut down to suit their new position. The remains of two temples of Dionysus have been found adjoining the stoa of the theatre, as well as an altar of the same god adorned with masks and festoons; the smaller temple probably dates from the 6th century B.C. and the larger from the end of the 5th or the beginning of the 4th century.

West of the theatre is the precinct of Asclepius, established in 420 B.C., where were discovered the foundations of the temple together with several inscriptions and a great number of votive reliefs offered by grateful invalids. A Doric colonnade with a double row of columns extended along the base of the Acropolis for a distance of 54 yd.; behind it in a chamber hewn in the rock is the sacred well mentioned by Pausanias. The colonnade was a place of resort for the patients; a large building close beneath the rock was probably the abode of the priests. East of the theatre and closely related to it was the odeum (concert hall) of Pericles, the only building which can be assigned to him, though he may have designed the first plan of the theatre too. This was a large rectangular hypostyle with probably six rows of six marble columns which would have replaced the original wooden columns at its restoration by Ariobarzanes of Cappadocia after its destruction by Sulla in 86 B.C. Plutarch says that the odeum imitated the tent of Xerxes, referring no doubt to the pointed roof of the building.

14. The Choragic Monument of Lysicrates.—The beautiful choragic monument of Lysicrates, dedicated in the archonship of Euaenetus (335–334 B.C.), is the only survivor of many such structures which stood in the "Street of the Tripods" to the east of the Dionysiac theatre, bearing the tripods given to the successful choragi at the Dionysiac festival. It owes its preservation to its former inclusion in a Capuchin convent. The monument consists of a small circular temple of Pentelic marble, 21½ ft. in height and 9 ft. in diameter, with six engaged Corinthian columns and a sculptured frieze, standing on a rectangular base of Piraic stone. The delicately carved convex roof, composed of a single block, was surmounted by the tripod. Another choragic monument was that of Thrasyllus, which faced a cave in the rock of the Acropolis above the Dionysiac theatre. A portion of another, that of Nicias, was used to make the late Roman gate of the Acropolis. In one of these monuments was the famous Satyr of Praxiteles.

15. Hellenistic Period.—After the age of Alexander Athens was adorned with many new buildings, a tribute paid to her intellectual renown by foreign potentates or dilettanti who desired to add their names to the list of its illustrious citizens and patrons. Among the first of these benefactions was the great gymnasium of Ptolemy II Philadelphus (*see* PTOLEMIES), built northeast of the agora about 250 B.C. Attalus I of Pergamum (*see* ATTALUS) set up a number of bronze statues on the Acropolis; Eumenes II of Pergamum (*see* EUMENES) built the long portico west of the Dionysiac theatre; Attalus II erected the magnificent stoa which closes the east side of the agora and which was completely rebuilt on the ancient plan in the closing stages of the American excavations in order to serve as a museum for the site. The stoa consisted of a row of 21 single-roomed shops, fronted by a double colonnade, the outer Doric and the inner Ionic. At each end there was a staircase approached through an arched opening—the earliest use of a visible arch in Athens—leading to a second story, again with shops, and a double colonnade—double Ionic at the front joined by a balustrade and Pergamene behind. About the same time the whole of the south side of the agora was drastically remodeled. A stoa (now known as the Middle stoa) some 160 yd. long was built between the southern end of the Stoa of Attalus and the Tholos, offering two colonnades, one facing north into the square and the other south toward the old South stoa; soon afterward a second stoa was added at right angles to its east end, again facing outward (to the Panathenaic way) and inward to what became a new enclosure; the replanning was then completed by the replacement of the old South stoa by a new one at right angles to the East stoa and connecting it with the Heliaea. The whole complex thus created a separate area for the conduct of Athens' legal business. A few years later the civic offices themselves were improved. The old complex had included, to the north of the council house, a small archaic temple (*Metroön*) dedicated to the Mother of the Gods; a building was then designed to fulfill the functions of both—one small room remaining as the sanctuary of the goddess, two others serving as deposits for the archives, while a spacious two-storied section to the north may have been an official residence. The whole was fronted with an elegant colonnade in Pentelic marble.

The greatest monument, however, of the Hellenistic period, the colossal temple of Olympian Zeus, stood by the Ilissus, southeast of the Acropolis. Its foundations were laid on the site of a small ancient shrine by Hippias, but the building in its ultimate form was for the greater part constructed, under the auspices of Antiochus IV Epiphanes, king of Syria, by the Roman architect Cossutius between 174 and 164 B.C., the date of the death of Antiochus. The work was apparently resumed under Augustus and finally, in A.D. 129, completed and dedicated by Hadrian, who set up a chryselephantine statue of Zeus in the cella. The building was octostyle; its length was 318 ft. and its breadth 132 ft. With the exception of the foundations and two lower steps of the stylobate, it was entirely of Pentelic marble and possessed 104 Corinthian columns, 56 ft. 7 in. in height, of which 48 stood in triple rows under the pediments and 56 in double rows at the sides; of these, 16 remained standing in 1852, when one was blown down by a storm.

16. Roman Period.—An earlier building of this period is the Horologium of Andronicus of Cyrrhus (otherwise known as the "Tower of the Winds"), still standing near the eastern end of the Roman agora. This may belong to the 2nd or 1st century B.C. It is an octagonal marble structure, 42 ft. in height and 26 ft. in diameter; the eight sides, which face the points of the compass, are furnished with a frieze containing inartistic figures in relief representing the winds; below it, on the sides facing the sun, are the lines of a sundial. It was surmounted by a weathercock in the form of a bronze Triton and contained a water clock to record the time when the sun was not shining.

The new, or Roman, agora to the north of the Acropolis, per-

haps mainly an oil market, was constructed after the year 27 B.C. It consisted of a large open rectangular space surrounded by an Ionic colonnade into which opened a number of shops or storehouses. The eastern gate was adorned with four Ionic columns on the outside and two on the inside, the western entrance being the well-known Doric portion of Athena Archegetis with an inscription recording its erection from donations of Julius Caesar and Augustus. On one theory the site of this agora had previously been occupied by a 5th-century temple of Ares (almost a twin of the Hephaesteum and undoubtedly the work of the same architect). There is no positive evidence for this but it is a curious coincidence that Ares' temple was dismantled and reassembled block by block in the old agora about the same time as the new agora was being built. Its foundations and a few architectural fragments can now be seen in the area between the temple of Apollo and the Panathenaic way. Space was further restricted by the construction (about 15 B.C.) of a massive odeum to the southeast of the temple on the site of the primitive orchestra. This, the gift of M. Vipsanius Agrippa, was a rectangular structure, entered from the terrace of the Middle Stoa, which contained seating for about 1,000 people on semicircular tiers of marble benches. The auditorium had a span of 27 yd. and this was roofed without any interior support—unwisely, for about A.D. 150 the roof collapsed. In the reconstruction which followed a crosswall was introduced which cut the capacity by about a half; at the same time the north front was adorned by the insertion of six colossal statues of giants and tritons supporting an architrave to form a colonnade in place of the original projecting porch. At the eastern end of the Acropolis a charming circular temple of white marble with a peristyle of nine Ionic columns was dedicated to Rome and Augustus. The conspicuous monument which crowns Museum hill was erected as the mausoleum of Antiochus Philopappus of Commagene, grandson of Antiochus Epiphanes, in A.D. 114–116. It was nearly square, but the only portion remaining is the slightly curved front, with three niches between Corinthian pilasters; in the central niche is the statue of Philopappus.

The emperor Hadrian was a lavish benefactor to Athens. He enlarged the circuit of the city walls to the east and so created the City of Hadrian (Hadrianopolis) or New Athens (Novae Athenae), a handsome suburb with numerous villas, baths and gardens; its walls were fortified with rectangular towers. The Arch of Hadrian near the Olympeum marked the boundary between the new and old cities. A vast rectangular enclosure immediately north of the new agora was identified as the library of Hadrian. A portion of its western front, adorned with monolithic unfluted Corinthian columns, is still standing—the familiar "Stoa of Hadrian"; another well-preserved portion, with six pilasters, runs parallel to the west side of Aeolus street. The interior consisted of a spacious court surrounded by a colonnade of 100 columns, into which five chambers opened at the eastern end. A portico of four fluted Corinthian columns on the western side formed the entrance to the quadrangle. A pantheon, a gymnasium and temples of Hera and Zeus Panhellenius were likewise built by Hadrian; the aqueduct, which he began, was completed by Antoninus Pius (A.D. 138–161); it is still in use. About the same time the generosity of one T. Flavius Pantainus provided a splendid library adjoining the Stoa of Attalus.

The stadium, in which the Panathenaic games were held, was first laid out by the orator Lycurgus (*see* above) about 330 B.C. It was an oblong structure filling a depression, partly natural, partly artificial, near the left bank of the Ilissus beneath the eastern declivity of the Ardettus hill. The immense building, however, which was restored in 1896 and the following years, was that constructed in Pentelic marble about A.D. 143 by Herodes Atticus, a wealthy Roman resident. The seats, rising in tiers as in a theatre, accommodated about 44,000 spectators; the arena was 670 ft. in length and 109 ft. in breadth. The odeum, built beneath the southwest slope of the Acropolis after A.D. 161 by Herodes Atticus in memory of his wife Regilla, is comparatively well preserved. The plan is that of the conventional Roman theatre; the semicircular auditorium, which seated some 5,000 persons, is, like that of the Dionysiac theatre, partly hollowed from the rock. The orchestra is paved with marble squares. The façade in Piraic stone, displays three stories of arched windows. The whole building was covered with a cedar roof. The structure without the roof has now been restored and is again in use as an open-air concert hall and theatre.

In the raid of the Heruli (*q.v.*), A.D. 267, much of the city was destroyed. The Athenians then abandoned the old defenses and a much smaller circuit was constructed, the so-called Valerian wall. This began at the present entrance to the Acropolis, followed the line of the Panathenaic way to the library of Pantainus, where a part is preserved, then incorporated the surviving shops of the Stoa of Attalus, turned east for about 500 yd. through the library of Hadrian and then returned to the Acropolis circuit. The material came from the shattered buildings outside, in the surviving portion of the agora which had lain desolate for a hundred years. Then, about A.D. 400, the old fortifications were resumed and the city came to life again; from this time dates the vast gymnasium complex in the agora covering the site of Agrippa's odeum (and incorporating the giants in a new stoa) and much of the Middle, East and South stoas. This probably served as part of the university of Athens until it was closed in A.D. 529.

II. HISTORY

1. Prehistoric Period.—Archaeology supplies the early history of Athens, for it is barely mentioned by Homer and the numerous legends have little historical value. Its Neolithic inhabitants, of the race that occupied most of Greece and was related to that of the Danubian and Carpathian areas, were followed by a bronze-using folk akin to the islanders and Cretans, possibly a non-Hellenic people. Next (perhaps at the turn of the Early and Middle Bronze Age) came the irruption of Hellenic peoples into the Aegean area, including Greece (*see* AEGEAN CIVILIZATION), and in the Late Bronze Age Athens became a strong castle like Tiryns with traces of a "palace" remaining unconquered though not unshaken by the Dorian invasion. Rich finds of Geometric vases indicate prosperity in the Early Iron Age.

At the dawn of history proper the independent communities of Attica were absorbed into a central state of Athens under a monarchy of Ionian affinities, for the people were divided into four tribes whose names—Geleontes, Hopletes, Argadeis and Aegicoreis—recur in several true Ionian towns. The centralization (synoecism), to which many Greek peoples never attained, laid the foundations of Athenian greatness; but in other respects the new constitution tended to arrest development. When the monarchy was supplanted in the usual Greek fashion by a hereditary nobility, all power was appropriated by a privileged class of Eupatridae (*q.v.*), who owed their predominance to their control over legal procedure; the Geomoroi and Demiourgoi, who formed the bulk of the community, enjoyed no political rights. The aristocratic council of the Areopagus (*q.v.*) constituted the chief criminal court and nominated the magistrates, among whom the chief archon (*q.v.*) passed judgment in family suits and controlled admission to the genos or clan and consequently the acquisition of the franchise. This system was further supported by religious prescriptions which the nobles retained as a corporate secret. The Eupatridae also tended to become sole owners of the land, reducing the original freeholders or tenants to the position of serfs. During this period Athens seems to have made little use of its militia, commanded by the polemarch, or of its navy, which was raised in special local divisions known as naucraries; hence no

military *esprit de corps* could arise to check the Eupatrid ascendancy. Nor did the commons obtain relief through any commercial or colonial enterprises as in many other Greek states. The first attack upon the aristocracy proceeded from a young noble named Cylon, who endeavoured to become tyrant about 630 B.C. The people helped to crush this movement; yet discontent must have been rife for, in 621, the Eupatrids commissioned Draco (*q.v.*) to draft and publish a code of criminal law. By this notable concession the nobles lost that exclusive legal knowledge which had formed one of their main instruments of oppression.

2. The Rise of Athens.—A still greater danger grew out of the widespread financial distress, which was steadily driving many of the agricultural population into slavery and threatened the entire state with ruin. After a protracted war with the neighbouring Megarians accentuated the crisis, the Eupatrids gave to one of their number, the celebrated Solon (*q.v.*), free power to remodel the whole state (594 B.C. or perhaps slightly later) and revise the Draconian code, a revision which was the basis for all later Athenian law and found many imitators elsewhere (*see* GREEK LAW). By his economic legislation Solon placed agriculture once more upon a sound footing and encouraged commercial enterprise, thus laying the foundation of material prosperity. His constitutional reforms proved less successful, for, although he put into the hands of the people safeguards against oppression, he could not ensure their use in practice. After a period of party feud among the nobles the new constitution was superseded by the autocratic rule of Pisistratus and his sons Hippias and Hipparchus. The age of despotism, which lasted, with interruptions, from 560 to 510, was a period of great prosperity. The rulers fostered agriculture, stimulated commerce and industry (notably the famous Attic ceramics), adorned the city with public works and temples and rendered it a centre of culture. Their vigorous foreign policy first made Athens an Aegean power and secured connections with mainland powers. They also weakened the undue influence of the nobles and created a national Athenian spirit in place of the ancient clan feeling.

The equalization of classes was already far advanced when, about 509, an Alcmaeonid named Cleisthenes (*q.v.*), who had taken the chief part in the final expulsion of the tyrants, acquired ascendancy as leader of the commons. His constitution (508–507) expressed the change of political feeling by providing a national basis of franchise and a new state organization. By making effective the powers of the ecclesia (popular assembly), the boule (council) and heliaea (judicial assembly or people's law court), Cleisthenes became the true founder of Athenian democracy.

This revolution was accompanied by a conflict with Sparta and other powers, but in the ensuing wars Athens worsted powerful enemies like Thebes and Chalcis (506). A bolder stroke followed in 500, when a force was sent to support the Ionians in revolt against Persia (499–494) and helped sack Sardis. After the failure of this expedition the Athenians became absorbed in a struggle with Aegina (*q.v.*). In 493 the prospect of a Persian invasion brought into power men like Themistocles and Miltiades (*qq.v.*), to whose firmness and insight the Athenians largely owed their triumph in the great campaign of 490 against Persia. After a second political reaction, the prospect of a second Persian war and the naval superiority of Aegina led to a strong policy: Themistocles overcame the opposition of Aristides (*q.v.*) and passed his famous measure providing for a large increase of the Athenian fleet.

In the great invasion of 480–479 the Athenians displayed a resolution which could not be shaken even by the evacuation and destruction of their native city. Though the traditional account exaggerates the services of Athens, ultimate victory was chiefly due to the numbers and efficiency of its fleet and the wise policy of Themistocles. (*See* GRECO-PERSIAN WARS.)

3. Imperial Athens.—After the Persian retreat and the reoccupation of their city the Athenians continued the war with unabated vigour. Led by Aristides and Cimon they rendered such prominent service as to receive in return the formal leadership of the Greek allies and the presidency of the newly formed Delian league (*q.v.*). The ascendancy acquired in these years eventually raised Athens to the rank of an imperial state. For the moment it tended to impair the good relations which had subsisted between Athens and Sparta since the first days of the Persian peril. But so long as Cimon's influence prevailed the ideal of "peace at home and the complete humiliation of Persia" was steadily upheld. Similarly the internal policy of Athens continued to be shaped by the conservatives. The only notable innovations since the days of Cleisthenes had been the reduction of the archonship to a routine magistracy appointed partly by lot (487), and the rise of the ten elective strategoi (generals; *see* STRATEGUS) as chief executive officers. But the triumph of the navy at Salamis in 480 and the great expansion of commerce and industry had shifted the political centre of gravity from the moderate democrats to the more radical party. Though Themistocles soon lost his influence, his party eventually found a new leader in Ephialtes and, after the failure of Cimon's foreign policy (*see* CIMON), triumphed over the conservatives. The year 462–461 marks the reversal of Athenian policy at home and abroad. By canceling the political power of the Areopagus and multiplying the functions of the popular law court, Ephialtes abolished the last checks upon the sovereignty of the commons. His successor, Pericles, merely developed the full democracy so as to secure its effectual as well as its theoretical supremacy.

The foreign policy of Athens was now directed toward an almost reckless expansion (*see* PERICLES.) Besides securing its Aegean possessions and its commerce by the defeat of Corinth and Aegina, its last rivals at sea, Athens acquired an extensive dominion in central Greece and for a time quite overshadowed the Spartan land power. The rapid loss of the new conquests after 447, however, proved that Athens lacked a sufficient land army to defend permanently so extensive a frontier. Under the guidance of Pericles the Athenians renounced the unprofitable rivalry with Sparta and Persia and devoted themselves to the consolidation and judicious extension of their maritime influence.

The years of the supremacy of Pericles (443–429) are the most glorious in Athenian history. In actual extent of territory the empire had receded somewhat, but in point of security and organization it now stood at its height. The Delian league lay under Athenian control, and the points of strategic importance were largely held by cleruchies (*q.v.*; *see* also PERICLES) and garrisons. Out of a citizen body of more than 50,000 freemen, reinforced by mercenaries and slaves, a superb fleet exceeding 300 sail and an army of 30,000 trained soldiers could be mustered. The city, with its fortifications extending to the port of Piraeus, was impregnable to a land attack. Athenian commerce extended from Egypt and Colchis to Etruria and Carthage, and Athenian manufactures, which attracted skilled operatives from many lands, found a ready sale all over the Mediterranean. With tolls and the tribute of the Delian league (*q.v.*), a large reserve was amassed in the treasury.

Yet the material prosperity of Athens under Pericles was less notable than its brilliant attainments in every field of culture. No city ever adorned itself with such an array of temples, public buildings and works of art as the Athens of Pericles and Phidias. Its achievements in literature were hardly less great. The Attic drama of the period produced many masterpieces, and the scientific thought of Europe in the departments of logic, ethics, rhetoric and history mainly owes its origin to a new movement of Greek thought which was largely fostered by the patronage of Pericles himself. Besides producing numerous men of genius itself Athens attracted all the great intellects of Greece. The brilliant summary of the historian Thucydides in the famous funeral speech of Pericles (delivered in the winter of 431–430), in which the social life, the institutions and the culture of his country are set forth as a model, gives an ideal picture of Athens in its greatest days.

The payment for public service which Pericles had introduced may have contributed to raise the general level of culture of the citizens, but it created a dangerous precedent and incurred the censure of notable Greek thinkers. Moreover, all this prosperity was obtained at the expense of the confederates, whom Athens exploited in a somewhat selfish and illiberal manner. The cry of "tyrant city" roused public opinion in Greece against

Athens and brought on the Peloponnesian War (*q.v.*), which ruined the Athenian empire (431–404). The issue was determined less by any intrinsic superiority on the part of its enemies than by the blunders committed by a people unable to carry out a consistent foreign policy and served since Pericles by none but selfish or shortsighted advisers. It speaks well for the patriotism of its commons that Athens, weakened by plague and military disasters, should have withstood for so long the blows of enemies from without and the damage inflicted by traitors within. (*See* THERAMENES.)

4. 4th Century B.C.—After the complete defeat of the Athenians by land and sea, it was felt that their former services on behalf of Greece and their high culture should exempt the city from total ruin. Though stripped of the empire, Athens obtained very tolerable terms of peace. The democratic constitution, which had been supplanted for a while by a government of oligarchs, was restored in 403 after the latters' misrule had brought about their own downfall. (*See* CRITIAS; THERAMENES; THRASYBULUS.) Indeed the spread of democracy elsewhere increased the prestige of the Athenian administration, which had now reached a high peak of efficiency. Athenian art and literature in the 4th century declined but slightly from their former standard; philosophy and oratory reached a standard which was never equaled in antiquity. Athens took a prominent part with a view to upholding the balance of power, joining the Corinthian league in 395 and assisting Thebes against Sparta from 378 and Sparta against Thebes from 369. Athenian generals and admirals—Conon, Iphicrates, Chabrias, Timotheus (*qq.v.*)—distinguished themselves and partially recovered their country's predominance in the Aegean, with a temporary renewal of the Delian league. When Philip of Macedonia began to grow formidable Athens seemed called upon once more to champion the liberties of Greece. This ideal, when put forward by Demosthenes (*q.v.*) and other orators, created great enthusiasm among the Athenians, who at times displayed their old vigour, notably in the campaign of 338, though this culminated in Philip's decisive victory at Chaeronea (*q.v.*). But popular opinion repeatedly veered back in favour of the peace party. With diminished resources Athens could not indeed hope to cope with the great Macedonian king. However much one may sympathize with the patriots, it must be admitted that in the light of hard facts their conduct appears quixotic.

5. Hellenistic Period.—Philip and Alexander, who sincerely admired Athenian culture and courted a zealous co-operation against Persia, treated the defeated city with marked favour. But the people would not resign themselves to playing a secondary part and watched for every opportunity to revolt. For an outbreak after Alexander's death (323) the regent Antipater punished Athens by the loss of the city's remaining dependencies, the proscription of the chief patriots and the disfranchisement of 12,000 citizens. The Macedonian garrison prevented the city from taking a prominent part in the wars of the Diadochi, the successors of Alexander. Cassander first placed Athens under Demetrius Phalereus (317–307); Demetrius Poliorcetes liberated it in 307; after the battle of Ipsus (301) it fell under the control of Lachares, who made himself dictator in 295 but lost the city to Poliorcetes next year. The Athenians regained their liberty while Macedonia was thrown into confusion by the Celts and in 279 rendered good service against the invaders with a fleet off Thermopylae. When Antigonus Gonatas threatened to restore Macedonian power in Greece, the Athenians, supported perhaps by Ptolemy II Philadelphus, formed a defensive coalition; but in the ensuing Chremonidean War a naval defeat off Andros led to the siege and fall of Athens (262) and the imposition of a Macedonian garrison. The latter was withdrawn in 229 by the good offices of Aratus of Sicyon (*q.v.*).

At this period Athens was altogether overshadowed by the great Hellenistic monarchies and even by the new republican leagues of Greece; but the prestige of past history now perhaps attained its zenith. The democracy was respected by the Macedonian kings; the rulers of Egypt, Syria and especially of Pergamum courted Athens by gifts of buildings and works of art, to which the citizens replied by unbecoming flattery, even to the extent of creating new tribes named after their benefactors. If Athens lost supremacy in the fields of science and scholarship to Alexandria, the city became more than ever the home of philosophy, while Menander and the other poets of the "new comedy" made Athenian life known throughout the civilized world.

6. Relations With the Roman Republic.—Athens entered into friendly intercourse with Rome in 228 and in the Roman interest endured the desperate attacks of Philip V of Macedonia (200–199). In return for help against King Perseus Athens acquired some new possessions, notably the great mart of Delos (*q.v.*), which became an Athenian cleruchy (166). Athens indirectly brought about the conflict between Rome and the Achaean league which resulted in the loss of Greek independence but the city itself yet remained free, with rights secured by treaty. In spite of the favours of Rome, the more radical section began to chafe at the loss of importance. This discontent was skilfully fanned by Mithradates VI Eupator, king of Pontus (*see* MITHRADATES), at the outset of his campaigns against the Romans. His emissary, the philosopher Aristion, induced the people to declare war against Rome and to place him in chief command. The town with its port stood a long siege against Sulla, but was stormed in 86. The conqueror allowed his soldiers to loot, but inflicted no permanent punishment upon the people. This war left the Athenians poverty stricken and stripped of their commerce; the city's only importance now lay in the philosophical schools, which were frequented by many young Romans of note (Cicero, Atticus, Horace, etc.) as a sort of university. In the great Roman civil wars Athens sided with Pompeius (Pompey), but received a free pardon "in consideration of her great dead." Similarly the triumvirs after the battle of Philippi condoned its enthusiasm for the cause of Brutus; and Mark Antony repeatedly made Athens his headquarters and granted it several new possessions, including Eretria and Aegina—grants which Augustus subsequently revoked.

7. The Roman Empire.—Under the new settlement Athens remained a free and sovereign city—a favour which was repaid by zealous Caesar worship. The emperor Hadrian displayed his fondness for the city by constructing new buildings and relieving financial distress; he also amended the constitution and instituted a new national festival, the Panhellenica. Under the Antonines the endowment of professors out of the imperial treasury gave Athens a special status as a university. The city's whole energies seem henceforth devoted to academic pursuits. The military training of youth was superseded by courses in philosophy and rhetoric; the chief organs of administration, the revived Areopagus and the senior strategus, became an education office. Save for an incursion by Goths in A.D. 267 and a temporary occupation by Alaric in 395, Athens spent the remaining centuries of the ancient world in quiet prosperity. The rhetorical schools experienced a revival under Constantine the Great and his successors, when Athens became the school of many notable men, including Julian, Libanius, Basil and Gregory of Nazianzus. The professors teaching there may be regarded as the last representatives of a humane and moralized paganism. The freedom of teaching was first curtailed by Theodosius I; the edict of Justinian (529), forbidding the study of philosophy, dealt the deathblow to ancient Athens.

BIBLIOGRAPHY.—The history of Athens before Alexander the Great is best studied in general histories of Greece (*see* GREECE: *History*); there are, moreover, fully classified bibliographies in the *Cambridge Ancient History*, vol. iii–vi (1925–27). For constitutional and political history *see* K. J. Beloch, *Die attische Politik seit Perikles* (1884); U. von Wilamowitz-Moellendorf, *Aristoteles und Athen*, 2 vol. (1893); G. de Sanctis, *Atthis: storia della repubblica ateniese dalle origini all' età di Pericle*, 2nd ed. (1912); P. Cloché, *La Politique étrangère d'Athènes de 404 à 338 A.C.* (1934); F. Jacoby, *Atthis: The Local Chronicles of Ancient Athens* (1949); C. Hignett, *A History of the Athenian Constitution to the End of the Fifth Century B.C.* (1952); A. H. M. Jones, *Athenian Democracy* (1958). For the later period see W. S. Ferguson, *Hellenistic Athens* (1911); J. Day, *An Economic History of Athens Under Roman Domination* (1942).

8. Byzantine Period.—The city now sank into the position of a provincial Byzantine town and is rarely mentioned in the chronicles. Already it had been robbed of many of its works of art, among them the "Athena Promachos" and the "Parthenos" of Phidias, for the adornment of Constantinople; and further spolia-

tion took place when the church of Hagia Sophia was built in 532. The Parthenon, the Erechtheum, the Theseum and other temples were converted into Christian churches and were thus preserved throughout the middle ages. The emperor Constans II spent several months there in 662–663. In 869 the see of Athens became an archbishopric. In 995 Attica was ravaged by the Bulgars under their tsar Samuel, but Athens escaped; after the defeat of Samuel at Belasitsa (1014) the Byzantine emperor Basil II came to Athens and celebrated his triumph by a thanksgiving service in the Parthenon (1018). From the runic inscription on the marble lion from the Piraeus it has been inferred that Harald Haardraade (*q.v.*) and the Norsemen in the service of the Byzantine emperors captured the Piraeus in 1040. Like the rest of Greece Athens suffered greatly from its Byzantine administrators. The letters of Michael Choniates, archbishop of Athens in the last quarter of the 12th century, bewail the desolate condition of the city.

9. Latin Rule: 1204–1458.—After the Latin conquest of Constantinople in 1204 Otto de la Roche was granted the lordship of Athens by Boniface of Montferrat, king of Thessalonica, with the title of *megaskyr* (*megas kyrios* = "great lord"). His nephew and successor, Guy I, obtained the title duke of Athens from Louis IX of France in 1258. On the death of Guy II, last duke of the house of La Roche, in 1308, the duchy passed to his cousin, Walter of Brienne. Walter, however, became involved in a quarrel with the mercenary bands of the Grand Catalan company (*see* ALMOGÁVARES), who overthrew him in the battle of the Cephissus (1311) and occupied his territories. At first they tried to set up their own government under Roger Deslaur (a friendly knight from Roussillon whom they had taken prisoner in the battle), but in 1312 they put themselves under the protection of Frederick of Aragon, king of Sicily, who sent his son Manfred to be duke of Athens. Catalan rule under nominees of the Aragonese-Sicilian dynasty continued for the greater part of the 14th century; it was shaken, however, by the attack of the Navarrese company (another band of mercenaries) in 1379 and was terminated in 1388, when the Florentine Nerio Acciajuoli, lord of Corinth, took the Acropolis. Nerio secured recognition as duke from Ladislaus of Naples in 1394, and the Acciajuoli dynasty lasted till 1458, when the Acropolis was taken by the Turks under Omar, the general of the sultan Mohammed II, who had occupied the lower city in 1456. When the sultan entered Athens he was greatly struck by its ancient monuments and treated its inhabitants with comparative leniency.

See K. M. Setton, *Catalan Domination of Athens, 1311–1388* (1948).

10. Turkish Rule: 1458–1833.—After the Turkish conquest Athens disappeared from the eyes of western civilization. The Parthenon was transformed into a mosque; the Propylaea served as the residence of the Turkish commandant and the Erechtheum as a house. In 1466 the Venetians succeeded in occupying the city but failed to take the Acropolis. About 1645 a powder magazine in the Propylaea was ignited by lightning and the upper portion of the structure was destroyed. Under Francesco Morosini the Venetians again attacked Athens in Sept. 1687; a shell fired during the bombardment of the Acropolis exploded a powder magazine in the Parthenon and the building was rent asunder. After capturing the Acropolis the Venetians employed material from its ancient edifices in repairing its walls. They withdrew in the following year when the Turks set fire to the city. The central sculptures of the western pediment of the Parthenon, which Morosini intended to take to Venice, were unskilfully moved and, falling to the ground, were broken to pieces. Several ancient monuments were sacrificed to provide material for a new wall with which the Turks surrounded the city in 1778.

11. Athens After Greek Independence.—Greek insurgents surprised the city in 1821 and captured the Acropolis in 1822; but in 1826 Athens again fell into the hands of the Turks, who bombarded and took the Acropolis in the following year (the Erechtheum suffered greatly, and the monument of Thrasyllus was destroyed). The Turks remained in possession of the Acropolis till 1833, when Athens was chosen as the capital of the new kingdom of Greece. Its subsequent history is that of the kingdom. In World War I it was the scene of the incidents of 1916–17 that led to the deposition of King Constantine by the Allies. Athens was spared aerial bombardment during World War II; the German occupation lasted from April 27, 1941, to Oct. 12, 1944. *See* also GREECE: *History*. (M. C.; A. J. B. W.)

III. THE MODERN CITY

1. Population.—Facing the Saronic gulf and islands of Salamis and Aegina to the south, the modern city is built around the ancient Acropolis and the crag of Mt. Lycabettus. With the increase in population and building activity since World War II, the suburbs have extended in a somewhat ragged fashion across the plain, in some places reaching the foothills of the amphitheatre of mountains. The area covered by the capital, together with its suburbs and port, the Piraeus, is 155 sq.mi.

The population of Greater Athens (comprising 57 communes) increased considerably after the War of Independence: from about 5,000 in 1834 to 1,124,109 in 1940 and to 1,852,709 in 1961. The population of the city proper in 1961 was 627,564. This rapid growth was largely due to the great influx of refugees from Asia Minor in 1922 and the migration of rural inhabitants from the provinces during World War II and the Communist rebellion (1946–49). By the 1960s Athens had become a bustling cosmopolitan city.

2. Layout and Principal Buildings.—At the conclusion of the War of Independence Athens was little more than a village of the Turkish type, the poorly built houses clustering on the slopes of the Acropolis. A few of the narrow, crooked lanes of this quarter still remain, contrasting with the regularly laid out streets of the modern city, which was for the most part designed by the German architect Eduard Schaubert (1804–68). It contains numerous squares and avenues and two big parks. Large apartment blocks replaced the older private residences. The old palace, beneath which is the monument to the Unknown Soldier, is a dull and uninspiring structure, now converted into a parliament house. It was designed by Friedrich von Gärtner (1792–1847), one of the many German architects working in Athens during the reign of King Otto (Otho) who were responsible for the construction of numerous 19th-century buildings in the capital. The adjoining palace garden, now open to the public, was laid out by the landscape gardener Friedrich Schmidt (1811–89) at the request of Queen Amalia. To the southeast, in Herodes Atticus street, lined with false pepper trees, is the new palace, built in 1891–97. Beyond lies the reconstructed stadium, scene of the revived Olympic games in 1896 (see *Topography and Antiquities*, above).

The academy, a typical example of neoclassical architecture designed by Theophil Hansen (1813–91), is constructed of Pentelic marble with richly coloured and gilded colonnades and pediments. Close by is the National and Capodistrian University of Athens (founded 1837), with a colonnade adorned with paintings, and the National library with a Doric portico. In the main public garden is the Zappeion, a large semicircular edifice with a Corinthian portico built in 1896. The Vouli (*i.e.*, Boule), or parliament house, possesses a good library. Other public buildings are the National Technical university (Polytechnic institute), the National theatre, the Gennadeion library, attached to the American School of Classical Studies, and many hospitals, schools and orphanages. The Byzantine museum, built around an atrium, was one of the residences of the duchesse de Plaisance (1785–1854). The 19th-century cathedral is devoid of architectural merit but some of the smaller, early Byzantine churches are interesting and beautiful, particularly the church of St. Theodore (mid-11th century), the Kapnikarea (mid-12th century) and the Old Metropolis (early 13th century). The Holy Synod, a permanent council representing the government of the church of Greece, is presided over by the archbishop of Athens and 12 metropolitans who must all reside in the city during their tenure of office.

The streets of the capital, with the exception of some main thoroughfares, such as University, Stadium, Academy and Patissia streets, are generally narrow and overcrowded. Queen Sophia and Syngrou (Singros) avenues link Syntagma square, the heart of the city, with the northern suburbs and the Phaleron coast respectively. From the west the city is approached along a magnificent highway,

running parallel to the ancient Sacred way.

After the successive extensions of the boundaries of Greece in 1881, 1912 and 1920, Athens increased rapidly as the focus of society, politics and trade. After 1922 whole new districts sprang up to house the great influx of refugees from Asia Minor, and marked improvements of the roads have made them popular residential suburbs. There is an electric railway to the Piraeus and a suburban line to the fashionable resort of Kiphissia.

3. Museums and Societies.—The museums are well arranged, and the remnants of ancient art which they contain have fortunately escaped injudicious restoration. The National Archaeological museum, founded in 1866, contains, among many notable works of art, the bronze youths from Marathon and Cerigotto, the Zeus of Artemisium, the colossal archaic Apollo from Sunium, the Scopaid heads from Tegea and the Demeter relief from Eleusis. Its unrivaled collection of prehistoric antiquities contains the treasures of Mycenae, found by H. Schliemann in the 1870s, by A. J. B. Wace in 1950–55 and by J. Papadimitriou in 1952. There are also terracottas from Tanagra and Asia Minor and numerous painted vases. The Epigraphical museum contains valuable historical inscriptions, while the Acropolis museum (opened in 1878) possesses an interesting collection of sculptures belonging to the archaic period, all found on the Acropolis. In the Polytechnic there is a historical and ethnological museum. The Numismatic museum is in the academy. The Byzantine museum is rich in examples of Byzantine painting, sculpture and embroidery. In the Benaki museum there are specimens of Byzantine, Coptic, Muslim and Chinese art, and a magnificent collection of national costumes. The reconstructed Stoa of Attalus serves as a museum for the agora. There are also a museum of decorative art, a national historical museum and a national gallery. Among Greek societies for encouraging the study of various branches of the arts and other learned subjects is the Greek Archaeological society, which is becoming increasingly active in the conduct of excavations. Foreign archaeological schools in Athens include those of France, Germany, the United States, Great Britain, Austria, Italy and Sweden.

4. Communications and Industry.—Athens, together with the Piraeus, is the terminus of all steamship and railway lines (the Peloponnesian and the main line which connects with Salonika and the direct route to central and western Europe). There are express-train services with London (via Ostend) and Paris. There are regular sailings of passenger steamers between the Piraeus and the main Italian, Turkish and Egyptian ports, as well as Marseilles and New York. Thanks to its geographical position, air communications from the Central airport 8½ mi. from the city link Athens, a centre of tourism, with practically all parts of the world, including London, New York and Paris. There are daily bus services to all important provincial cities, while small steamers from the Piraeus serve the islands of the Aegean and Ionian seas.

Since World War I Athens has become the hub of all mercantile business, export and import. With the Piraeus, it is the most important manufacturing town in Greece. There are cloth and cotton mills, distilleries, breweries, potteries, flour mills, soap factories, tanneries, chemical works, carpet factories, the last an industry established by the refugees from Asia Minor. Exports are tobacco, wine, oil, currants, marble and, more recently, bauxite and magnesite. Publishing is significant. The principal imports are coal, grain and manufacturing articles of all kinds. The city's water is supplied from the Marathon reservoir, built of Pentelic marble.

ATHENS, a city of Georgia, U.S., 70 mi. E. by N. of Atlanta, on hills overlooking the Oconee river; seat of Clarke county. (For comparative population figures *see* table in Georgia: *Population.*)

Athens was founded in 1801 as the seat of the University of Georgia, which had been chartered in 1785 (*see* Georgia: *Education*).

In 1953 the U.S. navy supply corps school moved to Athens from Bayonne, N.J., occupying what was formerly a part of the university campus.

Among the early 19th-century homes are the Benjamin Harvey Hill home, now the residence of the president of the University of Georgia; the Henry W. Grady residence; and the Lumpkin home where the Ladies' Garden club, the first garden club in the United States, was organized.

Athens is an important wholesale trade centre for northeast Georgia, and after mid-20th century, grew in importance as a manufacturing centre. It is located in a rich agricultural area which produces dairy and beef cattle and poultry. (M. B. Po.)

ATHENS, a city of Ohio, U.S., 75 mi. S.E. of Columbus on the Hocking river; seat of Athens county. (For comparative population figures *see* table in Ohio: *Population.*) It is adjacent to a large conservancy and recreational district which includes Wayne National forest, Zaleski State forest, the scenic Hocking hills and several artificial lakes. The principal manufactured products of the city are business machines and equipment, hand and bench tools, midget motors for scooters, small cars and trucks and printed publications. The Athens State Mental hospital and several area offices of federal and state agencies are located there.

Athens was platted as a university townsite in 1799 by the surveyors of the Ohio company under the direction of Gen. Rufus Putnam, and was chartered as a town by the territorial legislature in 1800. It became the seat of Ohio university, a state-supported institution, the outgrowth of American Western university established there in 1802 under the provisions of the Northwest ordinance of 1787. In 1804 the legislature of Ohio approved the charter and renamed the institution Ohio university (the first collegiate institution in the Northwest territory). It was opened to students in 1808.

Athens was made the county seat in 1805, incorporated as a village in 1811 and as a city in 1911. (G. J. Bl.)

ATHERTON, an urban district of Lancashire, Eng., lies 13 mi. W.N.W. of Manchester by road. Pop. (1961) 19,756. Area 3.5 sq.mi. The name of the old part of the town is Chowbent. The manor was held by the Athertons from King John's reign to 1738, when it passed by marriage to Robert Gwillym and subsequently to Lord Lilford. It is an early Presbyterian centre with a chapel built in 1645 (since demolished) and replaced by another (1722) which is now the Chowbent Unitarian chapel. During the rebellion of 1715 the pastor led some of his congregation against the Old Pretender. The lord of the manor held a court-leet and court-baron annually up to 1891, but in that year Lord Lilford sold to the local board the market tolls, stallages and pickages, and thereafter the courts lapsed. The earliest manufactures were the making of nails or "sparrow bills" and cotton spinning, the latter causing the rapid industrialization of the district. In time the chief sources of employment became cotton mills, collieries, iron foundries and the manufacture of nuts and bolts.

ATHETOSIS, the medical term for certain slow, purposeless and involuntary movements of the hands and feet. The fingers are separately flexed and extended, abducted and adducted in an entirely irregular way. The hands as a whole are also moved and the arms, toes and feet may be affected. The condition is usually caused by some lesion of the brain. The movements may or may not continue during sleep. They cannot be arrested for more than a moment by will power, and are aggravated by voluntary movements. (*See* Nervous System, Diseases of.)

ATHIS-SUR-ORGE, TREATY OF, the treaty concluded on June 23, 1305, between King Philip IV of France and the count of Flanders, Robert de Béthune, after the king's victory at Mons-en-Pévèle (1304) over the Flemings, who in 1302 had defeated the French at Courtrai. By it the count of Flanders, his brothers, the nobility of Flanders and the Flemish towns agreed to swear an oath of loyalty to the king and never to conclude any alliance to which he might object. The Flemings were to assist the king to punish anyone who broke the treaty, even if it were the count of Flanders himself. They were to supply the king for one year with 500 men at arms, and Ghent, Bruges, Lille, Ypres and Douai were to have their fortifications demolished.

count was to pay the king within four years the sum of £400,000 and to make him an annual tribute of £20,000. Every Fleming aged 14 and over had to swear to observe the treaty scrupulously and to give various sureties as to its fulfillment. The Flemish people strongly opposed the treaty, and during the next 20 years Philip IV and his successors had to engage in several military expeditions against Flanders in an effort to enforce it.

ATHLETE'S FOOT: *see* Skin, Diseases of.

ATHLETICS (ARTICLES ON): *see* Sports (Articles on).

ATHLETICS, a term commonly used in England for what are known in the United States as track and field sports (*q.v.*), which embrace events in running, jumping and throwing.

An athlete (from the Greek *athlon*, a contest) is one who takes part in any sort of contest involving physical activity, and in the United States athletics comprise not only track and field sports but the entire range of team and individual games and competitive activities, such as football, baseball, basketball, ice hockey, polo, swimming, tennis, fencing and golf.

The development of athletics in the 20th century progressed until it attained an important position in the national life of many countries, involving the expenditure of billions of dollars by millions of people from teen age on.

Most athletic sports are played on an amateur basis in schools, colleges and clubs, and in public park and recreation programs; but sports by professional athletes gained increasing popularity after World War I, particularly football (both U.S. and Canadian, and association football, or soccer), basketball, boxing, wrestling, ice hockey and golf.

HISTORY

Beginnings.—The earliest historical records of athletics are of the Grecian Olympic games (*c.* 800 B.C.). However, references in classical verse, such as the Homeric epics, and in the sagas of pagan heroes and gods indicate that contests of strength, speed and skill predate the historical era.

As early as the 5th century B.C., there was a division of athletes into amateurs, who competed for the love of the sport and for personal glory with no thought of material gain, and professionals, who used their athletic prowess as a means of earning a living. The latter were often recruited from the lower classes of society, including the slaves. The most famous class of professional athletes in ancient times were the gladiators who fought in Roman arenas. These were chiefly slaves captured in frontier wars. Their popularity ebbed in the Augustan era with the introduction of professional Greek athletes, skilled in the Olympic contests.

The ancient Olympic games were terminated by order of the emperor Theodosius in A.D. 394. (*See* Olympic Games. For Pythian and other Greek and Roman games *see* Games, Classical.)

Decline.—The history of athletics between the fall of Rome in the 5th century and the 19th century is quite sketchy. Religious festivals in the middle ages were often accompanied by rude ball games between rival towns and guilds. These were forerunners of the great spectator sports of the 20th century: soccer, baseball, tennis, football, etc. Contests of strength and skill were also common at harvest fairs. Other sports such as archery, shooting, riding and hunting were encouraged by rulers for their value in wartime.

Revival.—The coming of the Industrial Revolution in the mid-18th century and the later introduction of sports as a regular extracurricular activity in English public schools by Thomas Arnold (*c.* 1830) provided a spur which led to the great development of sports during the Victorian age in England.

Capping this athletic revival of the 19th century was the restoration of the Olympic games at Athens in 1896. As the 20th century dawned, interest in all competitive sports reached a peak and, despite two world wars and numerous minor hostilities, this interest continued to grow.

With the growth of popular interest in sports and with the gradual breakdown of class distinctions at all levels of society, the ancient wall between the amateur and professional athlete began to be broken down. The professional was still, at the start of the 20th century, one to be tolerated rather than accepted in polite society. His services were sought as a teacher in such sports as golf and tennis, but the concept of the "amateur gentleman" of sport, one who did not work for his living, was still popular until World War I.

The so-called "golden age" of athletics which followed that war wiped out the last vestige of this class distinction. Both professional and amateur athletic competitors such as George Herman ("Babe") Ruth in baseball; William Tilden in tennis; Walter Hagen in golf; Harold ("Red") Grange in football; Thomas Hitchcock, Jr., in polo; Paavo Nurmi in track; Don (later Sir Donald) Bradman in cricket; and Jack Dempsey in boxing captured the imagination of all classes of society and became national heroes.

The athlete after mid-20th century was likely to start his career as an amateur either in school, university or club competition. He would then move to professional status if his skills were strong enough. Only the most talented athletes in strictly amateur sports such as track, field, swimming, gymnastics, etc., remain in competition past the age of 25. Professional careers last, in some instances, past 40.

TRAINING

Ancient.—The training of an athlete in ancient Greece involved both physical and spiritual preparation. Candidates for the Olympic games and for other, lesser festivals were accustomed to live a celibate life in outdoor camps, devoting weeks and even months to arduous preparation. (*See* Olympia: *History*.)

Every precaution was taken to ensure that they were in prime physical condition for the games. Diet was strictly supervised and consisted chiefly of fresh cheese, dried figs, wheat bread and meats which are still the staples of training menus in the 20th century. Wine was allowed the Greek athletes in small quantities.

Competition consisted of running, leaping, hurling the discus and javelin, boxing and wrestling. In training, the athletes practised these events and also used other methods to strengthen their muscles, such as carrying heavy loads, lifting weights, bending iron rods and taming bulls. Few athletes were specialists in any one sport as the most important Olympic contests involved a combination of two or more events, such as the pentathlon (*q.v.*).

As religious preparation for the games, athletes sacrificed to the gods. Women were barred from the games at first, even as spectators. While competing, the athletes were naked, having their bodies salved with oil. Boxers wore a strap of leather, the *caestus*, bound tightly around the wrist and forearm.

It was considered a great honour to compete in the Olympic games and champions were treated as national heroes. All athletes swore an oath, calling upon the gods to witness that they would compete honourably, win or lose.

Modern.—While open religious practices are rare in modern athletics (they are retained in some forms of Japanese wrestling), the training-camp system has been preserved. The emphasis, however, in many modern sports is on the specialist. Such sports as golf, bowling, baseball and cricket lay greater emphasis on an athlete's technical skill than on his physical prowess. The long seasons of such sports as baseball, soccer, football and basketball also tend to minimize the importance of the training season, which becomes little more than an opportunity to retone muscles which have lost their co-ordination during the off season.

The purpose of training, whatever the sport, is to prepare the athlete, physically and psychologically, for competition. Physically, the concentration is on creating endurance, speed or strength, depending on the event. Psychologically, the athlete's mental attitude should be keyed so that he looks forward eagerly to the contest. The intensity of his eagerness should depend on the sport; a prize fighter normally will be more highly keyed than a tennis player.

Training procedures which fit almost all sports are walking, running, light calisthenics and light weight-lifting. The first

two exercises develop breath control and muscular endurance; the last two tone individual muscles and prepare the athlete for certain types of resistance he will meet in competition.

Once past the preliminary stages of conditioning his body, the athlete will concentrate on his individual specialty. In such sports as running and swimming, he will test himself at distances over and under those at which he usually competes to build up both endurance and speed. In team sports, he will first practise individual skills, such as batting, throwing and catching a ball in baseball. Then he will join with the other athletes in practising teamwork.

Medical examinations are required of most athletes before the training season begins; after that, large clubs and almost all schools and colleges employ a trainer who watches the condition of the athletes under his care. He checks their weight, examines and treats minor injuries, rubs them down with liniments to keep muscles loose after workouts and tapes sore or weak muscles.

The sport which requires the most intense training and highest degree of conditioning is running (*q.v.*), particularly over the longer distances. Methods of training vary, but a popular one introduced by Scandinavian runners after World War II is interval training, or *fartlek* (speed play), which consists of fast sprints alternating with long trots. It gives the distance runner more speed than the steady pacing of earlier methods and trains him to put on several bursts of speed during a race without tiring.

Attempts to train great masses of athletes were carried on in the U.S.S.R. and other eastern European nations after World War II with some remarkable results in sports such as gymnastics and distance running. These nations also carried physical culture for women far beyond anything attempted by other nations. There being, technically, no professional athletes under Soviet governments, amateur careers in these nations lasted far longer than in non-Communist countries.

ATHLETIC ASSOCIATIONS

Each amateur sport conducted on an international basis has its own federation, to which the various national federations belong. In addition, the international federations of the Olympic sports are affiliated with the Comité International Olympique (International Olympic committee [I.O.C.]), while the national federations are affiliated with the various national Olympic committees (*see* OLYMPIC GAMES). This complex organization grew from the 1896 Olympic revival, when it was decided to base the events on the program of the Amateur Athletic union of the U.S. For information on federations governing specific sports *see* articles on those sports, as FENCING; HOCKEY; SWIMMING; etc.

International.—Athletics (track and field) governing bodies sprung up in the latter half of the 19th century. Following upon the founding of the English Amateur Athletic association (A.A.A.) in April 1880 in an Oxford hotel there came the formation of the New Zealand A.A.A. (1887); the Amateur Athletic Union (A.A.U.) of the U.S.A. (1888); the A.A.U. of Canada (1888); Ligue Royale Belge d'Athletisme (Belgium, 1889); the South African Amateur Athletic and Cycling association (1895); Svenska Fri-Idrottsforbundet (Sweden, 1895); A.A.U. of Australia (1897); Ceskoslovenska Obec Sckolska-ustredi Lehke Atletiky (Czechoslovakia, 1897); Hellenic A.A.A. (Greece, 1897); Magyar Athlétikai Szövetség (Hungary, 1897); Federazione Italiana di Atletica Leggera (Italy, 1898); and Deutscher Leichtathletik-Verband (Germany, 1898).

In the 20th century national associations from more than 70 countries were formed. In 1913 in Stockholm, Swed., a world governing body, the International Amateur Athletic federation (I.A.A.F.), was set up and it is to this body that all national associations except that of Communist China, which withdrew in August 1958, became affiliated. The I.A.A.F., together with the world governing bodies of the other Olympic sports, is in turn affiliated, as stated, to the I.O.C. These associations sponsor annual national championship matches in their sports, and, except for track and field, most of them also promote world championship competition in non-Olympic years.

United States.—*The A.A.U.*—The Amateur Athletic Union of the U.S.A. was born in 1888 out of the arguments then being waged over professionalism. It took into its own hands the responsibility of certifying athletes as amateurs in a variety of sports. In 1889, it divided the U.S. into districts and claimed jurisdiction over 17 sports.

Collegiate Associations.—The development of sports in the United States during the 20th century brought into great prominence the associations which directly govern intercollegiate and interscholastic athletics. Chief among these are the National Collegiate Athletic association, the Eastern College Athletic conference and the National Federation of State High School Athletic associations.

The National Collegiate Athletic association (N.C.A.A.) was founded in 1905, at the urging of Pres. Theodore Roosevelt, as an advisory body for collegiate sports when there was a move to abolish football because players were being injured and killed. At first the group merely wrote rules for eligibility and competition, but in 1921 it conducted a track-and-field championship, thereafter branching out to do the same in other sports. The N.C.A.A. is organized into a number of geographical districts, each with a vice-president who serves on the council, the association's principal policy-making body. In 1948, it adopted a "sanity code" to regulate excesses in college recruiting policies. Thereafter, it penalized many schools for violations of this code, usually involving excessive financial aid to athletes or undue activities in inducing outstanding high school athletes to attend the offending institution.

Many college conferences are affiliated with the N.C.A.A., the largest being the Eastern College Athletic conference (E.C.A.C.), formed in 1938 with more than 20 subsidiary leagues and over 100 members. The E.C.A.C. grew from the Intercollegiate Association of Amateur Athletics of America (I.C.4-A.), a track-and-field organization founded in 1875. The I.C.4-A. is the oldest athletic organization in the United States; it conducts three annual meetings—an indoor and an outdoor track-and-field championship and a cross-country championship.

Some of the more important college conferences in the United States are the Western (Big Ten), Southern, Atlantic Coast and Ivy League. Each of these conducts its own championship matches and sets its own eligibility rules, always within the pattern established by the N.C.A.A. An independent association is the National Association of Intercollegiate Athletics, composed of smaller colleges and universities, some of them N.C.A.A. members.

High School Associations.—The National Federation of State High School Athletic associations was organized in 1920 at a meeting to discuss problems which had resulted from high school contests promoted by outside organizations and individuals. It conducts no championships and, in fact, frowns upon national meets and tournaments. It promulgates rules of competition and issues handbooks for various high school sports. It had more than 50 member associations in the latter half of the 20th century, representing more than 20,000 schools with a total enrollment of over 5,000,000.

Europe.—England and other European nations have no such highly organized intercollegiate competition as the United States. Athletics in these countries are conducted chiefly on a club basis, though universities such as Oxford and Cambridge engage in both intercollegiate and international competition. However, athletic events are strictly supervised and controlled. In England, a number of athletic clubs were formed as early as the 1860s, such as the West London Rowing club, which developed the first definition of eligibility for amateur competition. In all major sports, the European nations annually sponsor squads which take part in dual competitions as well as in world and regional championships. Club competition in the United States, on the other hand, deteriorated greatly during the first half of the 20th century as intercollegiate competition grew, and U.S. Olympic teams in track-and-field, basketball and other of the more popular sports were largely collegians.

See also GAMES, CLASSICAL; OLYMPIC GAMES; TRACK AND FIELD SPORTS; and, for a summary of titles of separate articles on sports and games, SPORTS (ARTICLES ON). (E. J. G.)

ATHLONE, GODARD VAN REEDE, Heer van Ginkel and 1st Earl of (1644–1703), Dutch soldier, who distinguished himself in the service of England, was born in June 1644 at Amerongen in Utrecht. He followed William of Orange to England in 1688 and took part in the suppression of a mutiny in a Scottish regiment. In 1691 he was made commander of the forces in Ireland. On June 30 that year he carried Athlone by storm, and on July 12 near Aughrim he decisively defeated and dispersed the Irish army, already disorganized by the death of its French commander, Saint-Ruth. Galway next capitulated, and Ginkel followed up this victory by a series of bold and successful manœuvres by which he captured Limerick, the Irish cavalry camp and the fort on Thomond bridge. The signing (Oct. 3, 1691) of a capitulation at Limerick completed his conquest of Ireland. For his services Ginkel received the earldom of Athlone and the barony of Aghrim in the peerage of Ireland. He died at Utrecht on Feb. 11, 1703. His British titles became extinct on the death of the 9th earl without issue in 1844. (J. P. K.)

ATHLONE (Áth Luain), an urban district in County Westmeath, Ire., on the river Shannon, 78 mi. W. of Dublin by road. Pop. (1961) 9,624. Area 1.9 sq.mi. A castle and a bridge were built by John de Grey, bishop of Norwich and justiciar of Ireland, in 1210. The first walls were erected in 1257. It became the seat of the presidency of Connaught under Elizabeth I and withstood a siege in 1641.

In the war of 1689 the town sustained two sieges, the first by William III, which failed, and the second by Gen. Godard van Ginkel in 1691. In 1797 the town was strongly fortified on the Roscommon side, but the works are now dismantled. Athlone was incorporated by James I and returned two members to the Irish parliament and afterward one member to the imperial parliament till 1885.

T. P. O'Connor, the politician and journalist, and John McCormack, the singer, were both natives of Athlone.

The river Shannon divides the town into two portions, the Leinster side (east) and the Connaught side (west). These are connected by a bridge, opened in 1844, the central portion of which is a swivel bridge. A lock communication with a basin renders the navigation of the river practicable above and below the town and permits pleasure cruises on the Shannon.

Athlone is an important agricultural centre and has a large cotton factory. The famous woolen mills, burned in 1940, are in production again. There are three Roman Catholic chapels, a courthouse and the Father Matthew hall, donated in 1952 and now housing the municipal offices and the library. About 1 mi. N. the Shannon broadens out into Lough Ree, which is famous for coarse fishing and is visited each year by thousands of anglers from all over Europe. The main transmitting station for Radio Éireann is at Athlone.

ATHOLL, EARLS AND DUKES OF. The territory of Atholl, together with Gowrie, originally formed one of the seven mormaorships of Scotland (*see* Mormaor), and its rulers became earls during the 12th century. In the 14th century the title was held by various members of the royal family. The Stewart line of the earls of Atholl originated with Sir John Stewart of Balveny (d. 1512), who was created earl of Atholl about 1457 (new charter, 1482).

John Stewart (d. 1579), 4th earl of Atholl in the Stewart line, succeeded his father, John, the 3rd earl, in 1542. As one of the principal Catholic nobles of Scotland, he was particularly trusted by Mary Stuart, but after the murder of Lord Darnley in 1567 he joined the Protestant lords against her and on her abdication was included in the regent's council for her son James VI. But he was again advocating her cause by 1569. He failed to prevent the earl of Morton's appointment to the regency in 1572, but succeeded, with the earl of Argyll, in driving him from office in March 1578, when James dissolved the regency and Atholl was appointed lord chancellor. Morton however regained his guardianship of James two months later. Atholl and Argyll, who were seeking assistance from Spain, then advanced to Stirling with a force of about 7,000 men, whereupon a compromise was arranged, the three earls being all included in the government. After a banquet held on April 20, 1579, to celebrate the reconciliation, Atholl became suddenly ill and his death on April 24 or 25 may have been caused by poison.

On the death in 1595 of his son John, 5th earl of Atholl, the earldom in default of male heirs reverted to the crown. Dorothea, daughter of the 5th earl, married (1604) William Murray, 2nd earl of Tullibardine, who in 1626 resigned that earldom in favour of his younger brother Sir Patrick Murray, on condition of the revival of the earldom of Atholl in his wife and her descendants.

John Murray (d. 1642), their only son, was accordingly created 1st earl of Atholl in the Murray line (1629). On the outbreak of the Bishops' War he called out the men of Atholl for Charles I and was imprisoned by the earl of Argyll in Stirling castle in 1640. He died in June 1642.

John Murray (1631–1703), 2nd earl and 1st marquess of Atholl (created 1676), son of the 1st earl, was born on May 2, 1631, and became a leading royalist. He was the chief supporter of the earl of Glencairn's rising in 1653, but was obliged to surrender a year later to George Monck, the Commonwealth commander in chief in Scotland. At the Restoration, Atholl received many high offices in Scotland and at first supported the tyrannical policy of the earl of Lauderdale, the high commissioner. But after the campaign of 1678, called the "Highland Host," in which he was among the leaders, he joined in a remonstrance to the king against the severities inflicted on the Covenanters and, although he was made vice-admiral of Scotland in 1680 and president of parliament in 1681, he was passed over for the chancellorship which became vacant in that year. Appointed lord lieutenant of Argyll in 1684, he had by 1685 become master of that region and at Inchinnan in June captured the earl of Argyll, who was leading an invasion in favour of the duke of Monmouth. In the revolution of 1688–89 he acted indecisively, although he took part in the proclamation of William and Mary as king and queen at Edinburgh. During Dundee's rebellion he retired to Bath to "take the waters," but became implicated in the Jacobite plot of Sir James Montgomery (1690) and subsequently in further similar intrigues. He received a pardon in June 1691 and acted later for the government in the pacification of the Highlands. He died on May 6, 1703. He married Amelia, daughter of James Stanley, 7th earl of Derby, through whom the later dukes of Atholl acquired the sovereignty of the Isle of Man (1736).

John Murray (1660–1724), 2nd marquess and 1st duke of Atholl (created 1703), was born at Knowsley, Lancaster, on Feb. 24, 1660. He favoured the accession of William and Mary in 1689, but was unable, during his father's absence, to prevent the majority of his clan under the command of his brother, Lord James Murray, from joining Dundee's rising. An attempt was made in 1703–04 by Simon, Lord Lovat, who used the duke of Queensberry as a tool, to implicate him in a plot against Queen Anne; but the intrigue was disclosed by Robert Ferguson and Atholl sent an explanation to the queen which resulted in Queensberry's downfall. Between 1705 and 1707 he vehemently opposed the union of England and Scotland, but on the score of illness, real or feigned, he took no part in the Jacobite invasion of 1708 and was kept under close watch in his castle at Blair (Perthshire). When the Tories came to power in 1710 Atholl returned to office and was high commissioner for Scotland from 1712 to 1714. He was dismissed on the accession of George I (1714), but at the rebellion of 1715, while three of his sons joined the Jacobites, he supported and assisted the government. He captured, on June 4, 1717, Rob Roy (Robert Macgregor), who succeeded, however, in escaping. Atholl died at Huntingtower, Perth, on Nov. 14, 1724.

John George Stewart-Murray (1871–1942), the 8th duke, married Katharine Marjory (1874–1960), daughter of Sir James Ramsay of Bamff, the historian. She was an M.P. from 1923 to 1938, and was parliamentary secretary to the board of education from 1924 to 1929. She published several books on international affairs. The present holder of the title, George Iain Murray (1931–), succeeded as 10th duke in 1957.

See *The Manuscripts of the Duke of Athole* (Historical Manuscripts Commission, 1891); S. Cowan, *Three Celtic Earldoms* (1909).

(G. S. P.)

ATHOLL or ATHOLE, a mountainous district in north Perthshire, Scot., area about 450 sq.mi., bounded on the north by Badenoch, on the northeast by Braemar, on the east by Angus (Forfarshire), on the south by Breadalbane, on the west and northwest by Lochaber.

It is watered by Tay, Tummel, Garry, Tilt, Bruar and other streams. Glen Garry and Glen Tilt are the chief glens, and Loch Rannoch and Loch Tummel the principal lakes. The population is mainly in Pitlochry and Blair Atholl (*q.v.*). Mountains with peaks reaching over 3,000 ft. (Ben-y-Gloe 3,671, Ben Dearg 3,304) enclose the Atholl basin whose floor level lies at about 1,500 ft. It can be entered by the pass of Killiecrankie (*q.v.*) on the south and of Drumochter on the north.

Pasture and a little cultivable land are found in the lower valleys. Red deer come down from the mountains to winter in the plains. Hydroelectric power stations have been constructed along the Tummel.

ATHOS, MOUNT, the most easterly of the three promontories of the peninsula of Chalcidice, Greece, which runs down from Macedonia into the Aegean sea. It is 30 mi. long and 6½ mi. wide at its broadest point, and has a mountainous spine thickly wooded at its northern end, culminating in the marble peak of Mt. Athos (6,667 ft.), which rises abruptly from the sea. The ancient name of the promontory was Acte. In 483–481 B.C. Xerxes cut a canal, traces of which are still visible, through its narrow neck to avoid taking his fleet round the treacherous cape. Under the name of the Holy Mountain (Ayion Oros), it is now a theocratic republic of Orthodox monks, inhabiting 20 monasteries and their dependencies, whose only town is its capital, Kariai (Karyes) (pop. [1961] 429). Of the total population (2,687 in 1961), which is exclusively male, less than 2,000 are monks, the remainder being lay officials and labourers.

Hermits first settled on Athos before 850 A.D., and by the 10th century had associated in small communities (Gr. *Lavrai*) under the general direction of a *protos*, with his seat at Kariai. In 963, however, the monk Athanasius of Trebizond, with the help of his friend and imperial patron, Nicephorus II Phocas, founded the first regular monastery, the Great Lavra, adhering to the rule of St. Basil as observed in the monastery of Studios in Constantinople. Athanasius was denounced as an innovator by the hermits; but in 971–972 the emperor John I Tzimisces settled the dispute by granting Athos its first charter or typikon. Two more monasteries, Vatopedi and Iviron, were built in the 10th century and several more in the 11th; and in 1046 Constantine IX ratified a second charter regulating the life of the greatly increased monastic population. In the 12th century the Russian monastery of St. Panteleimon or Rossikon was founded; and in 1198 Stephen Nemanya of Serbia and his son Rastko (St. Sava) built the monastery of Chilandari. Athos was plundered after the 4th crusade (1204), and again by the Catalans in 1307–09. But it revived in the 14th century, when many of the monks, notably St. Gregory Palamas, strongly upheld the doctrine of Hesychasm (*q.v.*). Andronicus II placed it under the jurisdiction of the patriarch of Constantinople; and by 1400 nineteen of the monasteries had been founded. The last built was that of Stavronikita (1542).

In the 15th century some of them abandoned the traditional communistic regime of a cenobitic community (Gr. *koinobion*), under the rule of an abbot, in favour of the more liberal idiorrhythmic system, in which the monks could possess personal property and be governed by two annually elected trustees (Gr. *epitropoi*). After the Turkish conquest of Salonika in 1430 the monks prudently submitted; but the tribute which they had to pay to the sultan led, despite the patronage of the rulers of Walachia, Moldavia and Russia, to the rapid impoverishment and decadence of their monasteries, and the increasing adoption of the idiorrhythmic system. It was in reaction against this development that there were founded (from the 16th century) the first sketes or ascetic settlements grouped round a common church as offshoots of the monasteries. In 1749 a vain attempt was made to revive intellectual life by the foundation of an Athonite academy. The patriarch Gabriel IV introduced successful reforms in a new charter in 1783; but, at the outbreak of the Greek War of Independence in 1821, a Turkish garrison of 3,000 troops did great damage to the monasteries and their libraries. In the 19th century Athos became an object of czarist imperialism, and the Russian monastery and its properties grew to enormous proportions. In Nov. 1912 it was liberated from the Turks by the Greek army; and the London conference of 1913, followed by the treaties of Sèvres (1920) and Lausanne (1923), declared it an independent republic under the protection of Greece.

Its present constitution was drawn up by the abbots and elders in 1924, and forms part of the Greek constitution of 1927. The Greek government is represented by a prefect; but the actual administration is in the hands of the Holy Community, composed of 20 annually appointed representatives, one from each of the "ruling" monasteries, and an executive committee of 4 monks, the Holy Epistasia, which dates from 1783. Eleven of the monasteries are at present cenobitic and nine idiorrhythmic, discipline and fasting being much stricter in the former. Dependent upon them are 12 sketes, some 200 *kellia* or smaller eremitical communities and several *kalyvai* or hermitages (Gr. *hesychasteria*), where anchorites and solitaries live in the greatest austerity and isolation. Most of the monasteries are built near the coast and consist of a quadrangle of buildings enclosing the main church; each has its tower or keep, which often houses the library. The churches contain some of the most important examples of Byzantine art and many miracle-working icons, relics and treasures; and the libraries, despite successive depredations, still possess a vast quantity of classical and medieval manuscripts, most of which have been catalogued. Since the 11th century no women have been allowed on Athos, which is dedicated to the Virgin Mary. The life of the monks is almost wholly devoted to prayer and fasting, although a small trade is done in icons and wood carvings.

The thousandth anniversary of the founding of the Great Lavra was celebrated in 1963, with festivities organized through the joint initiative of the ecumenical patriarchate and Greece.

ATITLÁN is an elevated mountain lake of spectacular beauty famous as a tourist attraction of Guatemala. It occupies a roughly kidney-shaped natural crater of tremendous depth, approximately 11 mi. long and 5 mi. wide, formed between a precipitous, curving mountain wall and three volcanoes, San Pedro, Tolimán and Atitlán, which at that point form the escarpment of the highlands on the Pacific side.

In addition to its scenic grandeur, the lake is noted for the Indian villages that dot its shores, the inhabitants of which wear hand-woven costumes identifiably similar but detectably distinct. Among the best-known villages are Santiago Atitlán, San Pedro la Laguna and San Lucas Tolimán on the south shore, and San Antonio Palopó on the east. The lake is important in the domestic economy of the villagers, and it forms a significant transportation link in local commerce between highlands and lowlands. There is an abrupt fall in elevation toward the Pacific. The lake has no known outlet. (W. J. G.)

ATJEH (ACHIN), a province in northern Sumatra, Indon., forms the northern extremity of the island. The boundary extends from Salahadji on the east coast just north of Aru bay to a point on the west coast about midway between Singkil and Barus. Pop. (1961) 1,628,983; area 21,387 sq.mi. Atjeh is divided into four districts. It is very mountainous, with long ranges running parallel with the axis of the island, but, except in the extreme north, there is a fairly wide coastal plain, narrower in the east than in the west. The rivers are short, run down sharply to the coast and have little value for shipping, except small native boats.

The ports of Atjeh are Uleelheue and Sigli on the north and Lhokseumawe and Idi on the east coast, but large vessels go to

the free port of Sabang (*q.v.*) on We Island, 50 mi. N. of Uleelheue. Uleelheue is the gateway to Kutaradja (Kota Raja), the capital of the province, which is situated on the Atjeh river, about 3 mi. up from the sea. Kutaradja (pop. [1956 est.] 26,473) still possesses remains of its former glory when Atjeh was the wealthiest and most powerful sultanate in northern Sumatra, but the modern town consists largely of wooden and atap-roofed houses, a large mosque, some modern residences, offices and business premises.

History.—The cradle of Atjeh is at the very north end of Sumatra, known to the Arabs in the middle ages as Alrami or Lamari. In the 13th century it became the first Muslim stronghold in the archipelago. By 1525 Achin, as it was then known, had gained control over the coastal lands that now are part of the province of Atjeh. Its power reached its height in the time of Sultan Iskandar Muda (1607–36); extending in Sumatra southward to Palembang on the east coast and Bengkulu (Benkulen) on the west coast, and including on the mainland the states of Johore, Pahang, Kedah and Perak. In this period there were frequent wars with the Portuguese, who had established themselves at Malacca.

At their first arrival the Dutch (1599) and the English (1602) tried to establish factories in Atjeh, but these and later attempts were unsuccessful. After a short-lived alliance of the Dutch and the Achinese (Atjehnese), when the latter helped the Dutch in capturing Malacca, 1641, the sultanate of Atjeh declined in influence under Dutch pressure.

When, after the Napoleonic Wars, the East Indies were restored to the Netherlands, the British government sought to keep Dutch influence out of Atjeh. The treaty of 1824 with the Netherlands stipulated that, although all of Sumatra was recognized as within the Dutch sphere of control, no proceedings hostile to Atjeh should be undertaken by the Netherlands. Piracy, which had been common in these waters, became worse, with the Atjehnese immune to any measures by the Dutch navy. After many Dutch requests, the reservation regarding Atjeh was formally abandoned by the British in 1871, and in 1873 the Dutch declared war on Atjeh. It became a drawn-out struggle in which periods of Dutch control alternated with fresh rebellions, ending only in the early years of the 20th century under the direction of Gen. J. B. van Heutsz (later Governor-General). Until the very end of Dutch colonial rule Atjeh remained a not fully pacified region.

Following Japanese occupation and surrender in World War II there was political upheaval, in which the petty nobles who had served the Dutch and the Japanese were liquidated, and the Muslim religious teachers (Ulama) came to power under the leadership of Daud Beureuh. These men soon found themselves in disagreement with the central government. They objected to Javanese domination of the republic, desired an Islamic rather than a secular state, feared Communist influence and felt neglected in the economic sphere. In 1953 there was open rebellion, which was not fully suppressed by central government forces nor solved by the creation of a separate province of Atjeh in 1956.

The People and Economy.—The Achinese (*q.v.*), a Malayan people and devout Muslims, occupy the lowlands and adjoining hills. In the interior highlands live the Gayos, also Muslim, but in speech and culture more closely related to the Batak (*q.v.*). Rice is the food staple; it is grown more under *sawah* (wet) culture than *ladang* (dry), and there are irrigation works for the crop. Pepper, copra, areca nuts and rubber are the chief exports. Cattle raising, fishing and coastal trade are of some importance. There are some petroleum fields along the east coast.

A narrow-gauge railway links Kutaradja with Uleelheue and across country with Sigli on the northeast coast and from there to Medan. *See* also SUMATRA. (J. O. M. B.)

ATKIN, JAMES RICHARD ATKIN, BARON OF ABERDOVEY (1867–1944), British judge whose career included much work on the relationship between crime and insanity, was born in Queensland, Austr., on Nov. 28, 1867.

Educated at Christ college, Brecon, and at Magdalen college, Oxford, he was called to the bar at Gray's Inn in 1891, was elected a bencher and took silk in 1906. He became a judge of the high court (King's bench division) in 1913, was promoted to the court of appeal in 1919, and became a lord of appeal in ordinary in 1928, when he was created a life peer.

Atkin was a judge of liberal views as well as of great learning. In the course of his career he pressed for a legal redefinition of insanity, and, in the famous case of *Liversidge* v. *Anderson* (1942 A.C. 206), he delivered a dissenting judgment seeking to restrict the freedom of the executive from judicial control in relation to wartime powers of internment. He took part in many government inquiries, being chairman of the committee on crime and insanity in 1924.

Atkin died at Aberdovey, Wales, on June 25, 1944.

(W. T. Ws.)

ATKINSON, SIR HARRY ALBERT (1831–1892), New Zealand statesman who was an outstanding figure in the various Conservative governments of 1879–90 known as the "continuous ministry," was born in England at Broxton, Cheshire, on Nov. 1, 1831. His family emigrated to New Zealand in 1853 and settled at New Plymouth. Atkinson, appointed captain in the Taranaki Volunteer Rifles in 1860, was known as a good bush soldier and competent leader. He entered parliament in 1861. As minister of defense in the government of Sir F. A. Weld (1864–65) he urged that it would be cheaper and more effective to use only colonial troops against the Maoris and remained an advocate of this policy of "self-reliance." After visiting England he re-entered the New Zealand parliament (1872), joined Sir Julius Vogel's cabinet (1874) and was prime minister himself from 1876 to 1877, when he was foremost in abolishing the nine provincial governments and rearranging the administration. In 1877 the Liberals defeated his Conservative party, but in 1879 he returned as colonial treasurer to face a depression which lasted 14 years. Atkinson applied the unpopular remedy of cutting all government salaries by 10%, replacing John Ballance's land tax with a heavier property tax and increasing other taxation. He was prime minister from Sept. 1883 to Aug. 1884 and again after the interlude of the Stout-Vogel ministry (1884–87), bringing more retrenchment, cutting salaries of the governor, ministers and members of parliament, raising duties to protection level and saving everywhere to balance his budgets. He continued in office until Dec. 1890.

Self-taught, rough-hewn, resourceful and confident of mastering anything by sheer application, Atkinson could overpower more eloquent colleagues by his command of financial detail. The depression compelled rigorous economy, but he was not unsympathetic to hardship and in 1882 he, unsuccessfully, proposed a state insurance scheme for the aged, sick, widowed and orphaned. Knighted in 1888, he died at Wellington on June 28, 1892.

(N. M. TA.)

ATKINSON, SIR WILLIAM NICHOLAS (1850–1930), British inspector of mines, who first established the part played by coal dust in mine explosions, was born at Loughor, Glamorgan, on Nov. 19, 1850. Entering the civil service in 1873, he served, in turn, as assistant inspector of mines for the Newcastle upon Tyne and Durham area, inspector for the Staffordshire district, superintendent-inspector for the south Wales area and divisional inspector at the home office. With his brother, J. B. Atkinson, he published a book on explosions in coal mines in which he astonished his contemporaries by proving that, in the absence of firedamp, explosions are propagated by coal dust alone. He contributed many valuable reports on explosions and mine ventilation in the districts he inspected and, with J. S. Haldane, described the composition and origin of blackdamp and its health hazards. Atkinson was president of the Institution of Mining Engineers, 1894–95, and was knighted in 1918. He died at Wolverhampton on Feb. 15, 1930. (C. W. D.)

ATLANTA, the capital of Georgia, U.S., and its largest city, in the north-central part of the state, 8 mi. S. of the Chattahoochee river; lying mostly in Fulton county, of which it is the county seat, but partly also in De Kalb county. It is the financial and commercial capital of the southeast, the transportation and communication centre of the region and also an important distribution, manufacturing, educational and medical centre. Besides being the regional headquarters for most business and industrial concerns of national scope, it serves as the seat of most of the

activity of the federal government in the southeast. Atlanta is the most populous city between Washington, D.C., and New Orleans, La., and it is the centre of a large standard metropolitan statistical area, comprising Clayton, Cobb, De Kalb, Fulton and Gwinnett counties and including Marietta (*q.v.*), Decatur (*q.v.*), College Park and Hapeville. Pop. (1960) city 487,455; standard metropolitan statistical area 1,017,188. For comparative population figures *see* table in GEORGIA: *Population; see* also *Population*, below.

The city is located on the Allegheny watershed in the foothills of the Blue Ridge mountains. It is on the northern edge of the Piedmont and, although within sight of mountain ranges, is only 300 mi. from the Atlantic and Gulf coasts. At 1,050 ft. above sea level Atlanta is one of the highest large cities in the U.S. Rainfall is evenly distributed throughout the year, and the average mean monthly temperature ranges between 43.2° F. in January and 78.1° F. in July. The climate is invigorating, and, because of the elevation, nights are cool even in summer months.

One of the important influences in the development of Atlanta's distinctive character is the fact that it is an inland city located on no major body of water or navigable stream. It owes its existence and development to the railroads, the location of which were determined by geography. Situated at the southern extremity of the Appalachian range, it has become "the Gate City of the South" through which most overland traffic must pass between the eastern seaboard and the region to the west. It is a relatively new city having been largely rebuilt after it was burned by Union troops in 1864. Although not laid out according to a plan, the business district is impressive. There are numerous residential areas within the city and its environs. Dogwood abounds and in the spring, when its blossom is intermingled with redbud, crab apple and azalea, the city attracts many visitors.

Atlanta is often described as the symbol of the new south, having risen like the phoenix from the ashes of the Civil War. It is also famed as the home of Coca-Cola, whose developer, Asa G. Candler (1851–1929), was an Atlanta builder. Of particular interest to the visitor are Peachtree Street, the Cyclorama, a gigantic painting of the battle of Atlanta; the Wren's Nest, home of Joel Chandler Harris (1848–1908), the creator of Uncle Remus; and Stone mountain, an outcrop of naked granite, 15 mi. S.E. of the city. Atlanta, peopled primarily by southerners of rural background until World War II, has since felt the impact of the immigration of many non-southerners who serve the regional business and government offices. The spirit of the city tends to be liberal within the framework of southern conservatism. The attractions tend to be traditional rather than exotic. Customs have been influenced by the predominantly Protestant church tradition in the Bible belt.

History.—The founding of Atlanta came late in the history of Georgia. Title to the territory was not acquired from the Creek Indians until 1821. In 1837 a spot near the present site of the Union station was selected for the southern terminus of a railroad to be built by the state northward toward Chattanooga, Tenn., on the Tennessee river. The village was appropriately called Terminus, but in 1843 when a charter was granted the name was changed to Marthasville, in honour of the daughter of Gov. Wilson Lumpkin; and in 1845, when the city was incorporated, the name was changed to Atlanta, which was suggested by the name of the railroad (the Western and Atlantic). By 1860 the Georgia railroad, the Central railroad of Georgia, and the Atlanta and West Point railroad had been completed to Atlanta to connect with the Western and Atlantic. The basis had been laid for Atlanta to become the principal inland transportation centre for Georgia and the southeast. Atlanta's population, however, had not reached 10,000.

During the Civil War Atlanta became a depot of supplies and the location of Confederate war industries. It was also the keystone of Confederate transportation east of the Mississippi. Its importance made it the military objective of Gen. W. T. Sherman's invasion of Georgia from Chattanooga, in 1864 (*see* ATLANTA, BATTLES AROUND). Confederate Gen. Joseph E. Johnston brought his smaller army intact across the Chattahoochee river by mid-July; but he was replaced July 17 by Gen. John B. Hood, who was expected to fight rather than to continue to retreat. The battles of Peachtree Creek, Atlanta, Ezra Church and Jonesboro sealed the fate of Atlanta. Confederate forces were defeated and forced to evacuate the city. Union troops entered on Sept. 2. Civilians were ordered to leave and Atlanta was converted into a military camp. On Nov. 15 Sherman departed on his famous "march to the sea" but not before the city had been fired and a large part of it burned.

During the Reconstruction period Atlanta was the centre of federal government activities. In 1867 it became headquarters for the 3rd military district under Gen. John Pope. Later in the same year it was the meeting place for the constitutional convention which drew up the Georgia constitution of 1868. It became the capital of Georgia under the Republican state administration elected in 1868.

Under the leadership of Gov. Joseph E. Brown, Sen. Benjamin H. Hill, *Constitution* editor Henry W. Grady and others, Atlanta came to epitomize the spirit of the new south, advocating reconciliation with the north in order to restore business. This spirit was dramatized by three expositions held in Atlanta: the International Cotton exposition in 1881, the Piedmont exposition in 1887 and the Cotton States and International exposition in 1895. At the latter Booker T. Washington made his historic declaration, known as the Atlanta compromise, urging the Negro to seek economic security before expecting political or social equality.

Atlanta political leaders were a dominant force in Georgia politics in the 1880s. The constitutional convention of 1877 was held in Atlanta when the final effort to return the capital to Milledgeville was defeated. The present state capitol building was completed in 1889. The Populist revolt of the 1890s (*see* POPULIST PARTY) dethroned Atlanta as the dominant power in Georgia politics. Although Atlanta men occupied the governor's office during most of the period 1906–1921, they were heavily dependent upon the rural voters. Thereafter their influence in state politics declined.

The method of apportioning representation in the state legislature, with its attendant county unit system required by law for nomination of state officials in the Democratic primary, gives Atlanta and other urban centres small voice in the affairs of Georgia although they provide most of the state's revenue. The tensions between Atlanta and the rest of Georgia are traditional but became intensified after World War II.

Population.—Since 1870 when the population reached 21,789 Atlanta has been the most populous city in Georgia. Following World War II, however, the rate of growth increased both in the city and the metropolitan area. The population of Atlanta was 89,872 in 1900; in 1930, after several annexations of territory it was 270,366. Since 1950, 90 sq.mi. have been added by annexation, bringing the total area to 126 sq.mi. After 1950 the rate of increase of population in the standard metropolitan statistical area was twice as great as that in the city.

About two-thirds of the total population of the city is white, about one-third Negro. The percentage of white population in the metropolitan area is higher. The majority of Atlanta's white population is of Anglo-Saxon origin. The most significant change in the nature of the population after World War II was the great influx of non-Southern whites. They give a flavour to Atlanta's intellectual and cultural climate that distinguishes it from the rest of the state.

Government.—From its beginning the government of Atlanta has been of the unicameral type with a mayor and aldermen. Two aldermen are selected from each of the eight wards. Since 1938 the powers of the mayor over appointments and finance have increased considerably. In 1950 a study commission reported an eight-point plan of improvement which was approved in a referendum in Fulton county on June 28, 1950. In 1951 the general assembly passed a series of acts embodying the principal features of the plan which laid the basis for co-ordination of city and county activities.

Transportation, Commerce and Industry.—The key to much of Atlanta's importance is its strategic location at the focal

point of a wide network of excellent transportation and communication facilities. It is the largest railroad centre in the south, being served by 15 lines of 8 railways. Airlines serve Atlanta through the Municipal airport, Atlanta naval air station, Dobbins air force base, Fulton county airport and Parkaire field. The city is also an important bus terminal and the city and immediate environs are served by a local system of buses and trackless trolleys.

A natural transportation and trading centre, Atlanta, headquarters of the sixth federal reserve district, also is the region's financial centre and an important telephone and telegraph communications centre. One of Atlanta's principal businesses is wearing apparel. More than 15,000 retailers purchase goods worth approximately $45,000,000 annually. Trade shows are also held each year in housewares, china and art and giftwares.

Although Atlanta ranks first in the south as a distribution centre, it has become increasingly important in industry. The more important manufactures include textiles, chemicals, furniture, food, iron and steel products, aircraft and automobiles. Nearly every industry of national scope has a branch in Atlanta either for production or for storage and distribution of goods.

U.S. governmental offices in Atlanta include those maintained by the department of health, education and welfare; Ft. McPherson; Third army headquarters; a naval air station; the department of agriculture; the Atlanta general depot; the communicable disease centre; and the treasury department.

Education.—The Atlanta public school system was established in 1870 and is an independent city system. Among the best known private preparatory schools are Georgia Military academy, Marist college, Westminster and the Lovett school.

Atlanta has numerous institutions of higher education. The Georgia Institute of Technology (opened 1888) is the engineering unit of the university system of Georgia. Oglethorpe university (originally operated at Midway, but reopened at Atlanta in 1916) is a small private college. Emory university (founded by the Methodist Episcopal Church South in 1915) incorporated Emory college, which was operated 1837–1919 at Oxford, Ga. Endowed primarily by the Candler and Woodruff families and their associates, it is well known regionally and highly regarded, particularly for its school of medicine. Agnes Scott college (founded in 1889) is a small college for women located in suburban Decatur. The Georgia State College is the municipal unit of the university system of Georgia and offers a wide variety of evening and day courses. Other important institutions include: High Museum School of Art, Columbia Theological seminary (Presbyterian), Southern College of Pharmacy, Southern Technical institute, Atlanta School for Speech Correction and Cerebral Palsy school. In addition to those mentioned there are three independent law schools and four business colleges.

Atlanta is a centre for Negro higher education. The most prominent institutions are: Atlanta university (founded 1865 by the American Missionary association), now a graduate school and leader in the co-operative effort to strengthen all Negro colleges in Atlanta; Morehouse college (men), established in Augusta in 1867 by the American Baptist Home Missionary society; Clark college, a coeducational institution founded in 1869 by the Freedmen's Aid society of the Methodist Episcopal Church; Spelman college (women), originally endowed by the Women's American Baptist Home Mission society in 1881; Morris Brown college, a coeducational institution founded in 1881 by the African Methodist Episcopal Church; and Gammon Theological seminary (Methodist), established and endowed in 1883 by Elijah Gammon. All these institutions, except Gammon, are located on adjacent campuses.

Hospitals.—Atlanta is the medical centre of the southeast. It has 18 general hospitals and 9 related institutions with a total of more than 4,000 beds. The Emory university school of medicine provides leadership, especially in research. It also provides professional services at Grady hospital, a municipal charity hospital. Adjacent to the Emory campus is the laboratory and administrative headquarters building for the communicable disease centre, a division of the U.S. public health service.

Culture and Recreation.—The Atlanta Public library, organized in 1899, contains more than 500,000 volumes. These are housed in the main library and 16 branch libraries.

Atlanta has more than 300 white churches with a membership totaling more than 300,000 representing 30 different denominations. Many of these congregations are large; more than 40 have memberships in excess of 1,000 each and are housed in magnificent structures. Approximately one third of the churches co-operate in the Atlanta Christian council. There are also more than 270 Negro churches with a membership of more than 80,000. The Southern Regional council, organized in 1944 to promote improved race relations, has its headquarters in Atlanta.

Atlanta has its own 80-piece symphony orchestra with resident conductor. The High Museum of Art has a collection of considerable distinction.

Two daily newspapers are published: the *Constitution*, established in 1868 and developed by Henry W. Grady and Clark Howell; and the *Journal*, established in 1883 and developed by Hoke Smith and James R. Gray. Bitter rivals, politically and professionally, they were merged in 1950 under the ownership of Atlanta Newspapers Incorporated. Each has continued to operate an independent daily issue, but the Sunday edition was combined. There are 12 commercial radio and 3 television stations.

Atlanta maintains 150 parks and other areas for public use, including a zoo, in an area of about 3,000 ac. All Atlanta golf courses, seven of which are municipally owned, have grass greens playable the entire year. Within 50 mi. are Lakes Allatoona and Lanier for boating. (J. C. WA.)

ATLANTA, BATTLES AROUND, major engagements of the American Civil War (*see* AMERICAN CIVIL WAR). By the end of 1863, with Chattanooga and Vicksburg firmly in Union control, Atlanta became the logical point of attack in the western war. Distant from earlier fighting, Atlanta had become an important Confederate railroad, supply and manufacturing centre and gateway to the lower south. Hardly less important than strategic conquest would be the effect on morale and politics. New southern areas would learn the harsh realities of war, while the north would be encouraged by a solid victory won in time to influence the presidential election of 1864.

The fighting around Atlanta (July 20–Sept. 2, 1864), the last phase of the Atlanta campaign (May–Sept.), ended with Gen. W. T. Sherman forcing Confederate evacuation and presenting Lincoln with the key to political victory. Having pushed the Confederate defenders under Gen. *J. E. Johnston* back to the northern approaches to Atlanta, Sherman's double objective was to capture the city and destroy the defending army if the latter could be struck in the open field. To prevent possible reinforcement from Virginia, Sherman opened his maneuvers by moving against the Augusta railroad east of Decatur. He sent one of his three armies to cut the line beyond Decatur and two against Decatur, after which the three would unite and advance west on Atlanta.

Johnston, after months of delaying actions and retreats, was ready to defend Atlanta. His army, when reinforced by the Georgia militia, would be almost as large as that of Sherman, who had to leave troops behind to guard his supply line. *Johnston* had fortified a defense line on Peachtree creek north of Atlanta, from which he planned to take the Federals in the flank. On July 17, however, he was removed from command on orders of Pres. *Jefferson Davis*, and replaced by Gen. *John B. Hood*, whose forte was vigorous attack. Georgia politicians put pressure on officials in Richmond to remove *Johnston*, whose views on the situation appeared defeatist. *Hood* decided to attack at once. Sherman's forces were strung out for ten miles, with a dangerous gap between two of his three armies. *Hood* sent Gen. *William J. Hardee* with two of his three corps to assault Gen. George H. Thomas's army of the Cumberland as it crossed Peachtree creek. Thomas beat off all attacks (July 20). *Hood* then mounted a heavier attack, to begin against the exposed flank and rear of Sherman's left wing, Gen. James B. McPherson's army of the Tennessee. *Hardee's* corps was sent on a night march (July 21) around the Federal left. After *Hardee* had surprised and driven McPherson, *Hood* planned to rush out with his remaining two corps and roll up the Union line from south to north.

Hardee's flank march gave the defenders their best opportunity of the campaign. McPherson's cavalry was off tearing up the Augusta railroad, and *Hardee* achieved surprise as the Federals moved into abandoned Confederate trenches east of Atlanta. Attacking from thick woods, *Hardee* partially broke through to the Tennessee rear while *Cheatham's* corps assaulted the front. McPherson was killed as he rode into the unexpected fray. Logan assumed command and stabilized the Federal position after the hottest fighting of the campaign. The army of the Tennessee fought this, the battle of Atlanta (July 22), practically unaided.

The battle taught Sherman that his objective was too strongly held to be taken by storm and that *Hood's* army defied destruction. He determined, therefore, to deal with *Hood* by cutting off his supplies. Sherman moved the army of the Tennessee from the left wing to the right, appointed Howard its regular commander, and sent it around west of Atlanta against two railroads reaching the city from the south. *Hood* concentrated on holding the line from Macon. He delivered his third assault (July 28) against Howard at Ezra Church, southwest of Atlanta, accomplishing nothing except adding to his losses. Sherman continued to push south until his lines were stretched too thin for safety. He again changed his tactics, deciding to abandon his base and throw nearly his whole force against the railroads below Atlanta. This movement gave *Hood* a chance of saving Atlanta, if he could strike the Federals as they changed position. Instead, he was completely baffled, thinking Sherman was retreating north. Not until the Federals were across one railroad and on the other did *Hood* learn where they were. A final attack on Howard at Jonesboro failed (Aug. 31), and *Hood* hastily evacuated the next day.

(WI. E. B.)

ATLANTES, in architecture, male figures used as supports for an entablature, a balcony or other architectural projection, especially when such figures are posed as though they were actually upholding great weights, like Atlas carrying the world. The singular form is atlas. Male figures resembling the female caryatides (*see* CARYATID) are more properly known as canephoroe (*q.v.*) or telamones; half figures are known as terms. The earliest example of true atlantes occurs on a colossal scale in the temple of Zeus at Agrigentum (*c.* 500 B.C.). They were favourite motifs in the later Renaissance, particularly in Italy, Germany and France.

ATLANTIC, COMMAND OF THE. The voyages of exploration, dating from the later 15th century, shifted the maritime centre of gravity from the Mediterranean sea to the Atlantic ocean. Portuguese navigators crept southward along the African coast, rounded the Cape of Good Hope and blazed an all-sea route to India. Columbus, sailing westward for the same destination, stumbled instead into the Americas. Succeeding explorers gradually filled in the map of the new world. After the explorers came traders, colonists and buccaneers—Portuguese, Spaniards, Frenchmen, Englishmen and others—who fought the elements, the natives and each other, in a struggle for empire in America and for control of the sea routes connecting the new world with the old.

Dominance of British Sea Power.—Transformation of the Atlantic from a deserted waste into a vast arena of commercial and military activity profoundly altered political relationships in the old world. Lands fronting only on the Mediterranean lost in relation to those facing the Atlantic. In a long succession of wars (analyzed in the historical works of Capt. Alfred Thayer Mahan), Britain successfully contested the sea power of Spain, Holland and France. As a result of this epic struggle Great Britain became the dominant Atlantic power. By 1815, after the victorious close of the Napoleonic wars, British sea power had come literally to envelop the vast land mass of Eurasia-Africa from the North cape to the coast of China.

This far-flung *Pax Britannica,* as it was sometimes called, rested upon a remarkable combination of political, military and technological factors. For reasons beyond the scope of this article England experienced the Industrial Revolution earlier than its continental rivals. British imports of foodstuffs and raw materials and exports of manufactures flowed in ever-increasing volume along the ship lanes to and from the British Isles. The profits from this traffic were divided between further industrial development and support of the Royal Navy, which guarded the life lines of Britain's global empire.

Geography facilitated this task of the Royal Navy. The British Isles interposed a great barrier between northern Europe and the Atlantic ocean. To reach the ocean all sea-borne commerce to or from that region had to pass through the English channel or round the stormy northern tip of Scotland. The Rock of Gibraltar, taken by British arms in 1704, guarded the narrow strait which afforded the only marine exit from the Mediterranean down to the opening of the Suez canal. In Gibraltar, moreover, Britain possessed a formidable military stronghold separating the Atlantic and Mediterranean coasts both of France and of Spain. The island of Malta, which passed into British hands during the Napoleonic wars, somewhat similarly divided the eastern and western basins of the Mediterranean. Portugal was the only European country which suffered no strategical handicap that rendered it inherently vulnerable to the pressure of British sea power; but Portugal possessed neither the manpower nor the material resources necessary to remain a serious contender for the Atlantic trident after the onset of the industrial revolution.

Geography thus compelled most of the transatlantic, and much of the coastal, traffic of Europe to pass through narrow seas under the guns of the Royal Navy. British squadrons, patrolling the channel and the North sea within easy reach of their protected anchorages, afforded a constant reminder that British sea power had repeatedly in the past, and presumably could again, cut off northern Europe from sea-borne supplies. British squadrons in the Mediterranean afforded an equally impressive reminder of Britain's presumptive ability to halt the flow of traffic to and from the ports of southern Europe. British fleets could usually engage their continental foes without uncovering either the British Isles or a safe line of retreat to their own defended bases. British forces in the channel and North sea were favourably situated to interrupt communications between any hostile coalition of northern and western continental powers. By blockading the Strait of Gibraltar, Britain could divide the naval strength of Spain and especially of France, the country generally regarded during the 19th century as Britain's most dangerous maritime rival.

Primitive overland communications prevailing in Europe well down through the 19th century enhanced the strategical advantage which Britain derived from geographical position and a strong navy. There were no motor vehicles, almost no all-weather highways and only the rude beginnings of a railway system upon the European mainland. Large-scale movements of people or freight were next to impossible except by sea—and Great Britain commanded the sea right up to the coast of Europe. There was no escape from the paralyzing effects of sea blockade, and no way of countering the superior mobility which gave British sea power such a leverage on the continent.

Defensively, Britain's position was likewise secure. The fleets which stood ready to block the ocean portals of Europe simultaneously barred hostile approach to the British Isles. The automotive torpedo did not appear until 1860 and did not pass into general use for several decades thereafter. There were no submarines to steal through the blockade and raid British merchant shipping on the high sea. There were no bombing planes to rain destruction upon the ships, docks and factories of Great Britain.

British sea power dominated not only the ocean portals of Europe but all navigable passages leading from the Atlantic to the Indian and Pacific oceans as well. Acquisition of the Cape of Good Hope (1805) and of the Falkland Islands (1832) clinched the Royal Navy's hold on the only two sea routes to India and the far east down to the opening of the Suez canal. Occupation of a strategical site in the Gulf of Aden at the foot of the Red sea

(1839), together with naval stations at Gibraltar and Malta, assured Britain a secure hold on that marine short cut which connected the Mediterranean sea with the Indian ocean in 1869.

British sea power likewise dominated the western Atlantic down to the end of the 19th century. During the American Revolution, it is true, the French fleet of Admiral François J. P. de Grasse had wrested control of North American waters long enough to compel the surrender of Cornwallis at Yorktown in 1781. The resulting establishment of the United States raised a potential threat to Britain's permanent dominance in that region by laying the foundations for an independent, well-located and ultimately formidable power centre in North America. But it was more than a century before the new republic developed into a serious contender for command of the American seas. Meanwhile, from its bases in Nova Scotia, Bermuda and the West Indies, the Royal Navy continued to exert strong influence on sea communications throughout the western Atlantic. Squadrons operating from these bases blockaded United States ports in the War of 1812; and repeatedly thereafter the pressure of British sea power made itself felt at critical stages in Anglo-U.S. diplomacy.

This was especially the case during the long struggle for control of the Central American isthmus and of the Atlantic approaches thereto. Britain already possessed Jamaica, Trinidad and other strategical positions in this region. In addition, British leaders coveted the Spanish island of Cuba which screened the gulf coast of the United States in much the same manner as the British Isles covered the coast line of northern Europe. Another British objective was to control the various routes for a ship canal to the Pacific. Success in those aims would have strengthened British influence throughout the western hemisphere, and in particular would have given Britain a leverage on the United States comparable to that which it already held over Europe.

Anglo-American Relations.—American statesmen were awake to this danger. In framing the Monroe Doctrine (1823), in which the United States warned the monarchies of continental Europe to keep their hands off the newly liberated Spanish colonies in the western hemisphere, Secretary of State John Quincy Adams rejected overtures for a joint Anglo-U.S. declaration, lest such a move estop the United States later from turning the Monroe Doctrine against Great Britain itself. That contingency actually arose in the 1840s when Britain and the United States began a seesaw struggle for key positions in the Caribbean and in Central America, on the outcome of which depended the future command of the western Atlantic.

An uneasy truce was reached in the Clayton-Bulwer treaty of 1850. British pressure in this region was further eased from time to time by the diversionary effects of the Crimean War and subsequent European developments involving British interests. The phenomenal rise of United States industrial and military potential during and after the Civil War (1861–65), culminating in rapid naval expansion toward the close of the century, confronted Britain with the choice either of steadily strengthening its naval establishments in the American seas or of gradually losing command of those waters and therewith any possibility of controlling the future isthmian canal.

European complications again resolved this dilemma in favour of the United States. At the close of the Napoleonic wars, the Royal Navy was safely superior to all continental rivals. The long struggle had produced no radical changes in naval design. Technical stability meant slow obsolescence, a decided advantage to the leading naval power. By mid-century, however, a technical revolution was in full swing. The transition from sails to steam, from solid shot to explosive shells, from smooth bores to rifles, from wooden walls to armour—all these and other technical advances speeded obsolescence, and gave Britain's continental rivals a chance to compete on more nearly even terms. These technical developments also produced unsettling effects on political relations and behaviour, which in turn stimulated naval expansion. The resulting sense of insecurity was further aggravated by the growth of German political potential after the Franco-Prussian War (1870), and by the world-wide struggle for colonies, raw materials, protected markets and other imperialistic phenomena which accompanied the later stages of the industrial revolution.

In the late 1870s France, Russia, Italy and then Germany all began modernizing and expanding their navies. For a time the British government tended to regard France and Russia as the most dangerous rivals. With that combination in view, the British admiralty in 1889 publicly announced a "two-power standard" as the irreducible minimum to insure Britain's control of European waters and of the long sea routes to India and the far east. Gradually, however, British anxiety was transferred to Germany. The British watched German industrial and military growth with misgivings, heightened after 1890 by the aggressive overtones of German foreign policy. When Germany in 1900 launched a naval building program designed to break Britain's exclusive grip on the European seas, the effect was to bring about a fundamental reorientation of British policy.

To meet the rising German threat required the utmost concentration of British naval strength in European waters. Simultaneously to contest in the American seas the rapidly growing naval power of the United States was out of the question. Britain had no choice but to recognize U.S. primacy in the western Atlantic; and British statecraft proceeded with considerable finesse to derive from this necessity as much benefit as possible. A continuing and generally successful effort was made to settle outstanding disputes with the United States and to cultivate its good will in order that that country might safely be stricken from Britain's list of potential enemies. In the Hay-Pauncefote treaty of 1901, British statesmen even relinquished their long cherished ambition to share in the control of the future isthmian canal. And by 1904 the British admiralty had begun reducing its squadrons in American waters.

The first fruits of this reorientation were soon apparent. When European sympathies ranged almost solidly against Britain during the Boer War (1899–1902), U.S. statesmen countered with quiet but unwavering diplomatic support. Thereafter, as crisis followed crisis in Europe, and as the German empire made increasingly menacing gestures toward the western hemisphere, the weight of the United States was ranged consistently on the side of Great Britain in a manner that strongly suggested the possibility of an Anglo-U.S. naval coalition if such were necessary to hold the Atlantic against the steadily encroaching menace from the European continent.

The German menace had the further effect of suppressing at least temporarily the ancient rivalry between Great Britain and France. The Anglo-French entente of 1904 left Britain free to develop a fleet base at Alexandria near the Mediterranean terminus of the Suez canal and recognized a French protectorate over Morocco except for a coastal strip facing Gibraltar. This understanding was accompanied by marked improvement in Anglo-French naval relations, permitting withdrawal of British fleet units from the Mediterranean. The entente thus brought about a further strengthening of the northern sea frontier; but, like the parallel if less formal understanding with the U.S., this step too represented a dissipation of that exclusive command of the Atlantic which had once been the cornerstone of British naval policy.

While bargaining for allies and simplifying their strategic commitments, British statesmen steadily enlarged and strengthened the Royal Navy. Despite Germany's utmost efforts, the Royal Navy held its lead. In first-class capital ships, then regarded as the true index of naval power, the British fleet outranked Germany's in 1914 by a ratio of three to two. And the Anglo-French coalition, to which were added the naval resources of Russia, Japan, later Italy and eventually the United States, held an overwhelming preponderance of naval force measured in tons and guns.

World War I.—Following the outbreak of World War I in 1914, the Allies, under the leadership of Great Britain, skilfully translated this mathematical primacy into an effective command of the Atlantic and adjoining narrow seas. Within a few days their naval forces drove the German merchant flag from the high seas. Within a few weeks the German oversea cruiser squadrons were run down and destroyed or driven to cover. The main British fleet screened the transport of the British army to France, while the German fleet lay at anchor or cruised near its home bases in the

North sea, unwilling to risk a decisive battle and powerless to break up the blockade which the Allies drew tighter during the winter of 1914–15.

In Feb. 1915 the German command countered the Allied blockade with a submarine offensive against merchant shipping in a "war zone" surrounding the British Isles. Shortage of submarines, threats of U.S. intervention and other factors presently led to partial relaxation of this initial assault on Allied communications, but not until it had revealed the frightful commerce-destroying ability of the submarine, previously regarded with scepticism as a more or less useful auxiliary of the fighting fleets.

The temporary slackening of the submarine offensive was followed by increased activity on the part of the German high sea fleet. Late in May 1916 the German and British fleets met in the battle of Jutland. In this, the only major fleet action of the whole war, the fate of the Allies hung momentarily in the balance. A decisive defeat, shattering British sea power and transferring command of the Atlantic to Germany, would have constituted irretrievable disaster. No such catastrophe occurred. The German fleet, with skilful handling and exceptional luck, managed to inflict serious injury and then escape, though not without substantial casualties, from the annihilation that would certainly have been the outcome of a finish fight with Britain's grand fleet.

The battle of Jutland apparently convinced the German command of its inability in this way to smash the Anglo-French command of the Atlantic and thereby to raise the blockade. Only the submarine remained. U-boat construction was stepped up. The scope and area of submarine operations were gradually enlarged. Finally in Feb. 1917 the German command ordered a general submarine offensive against all merchant shipping, neutral as well as belligerent, in a desperate gambling attempt to starve Britain into surrender before an effective antisubmarine defense could be developed, and before the eventually certain intervention of the United States could turn the tide for the Allies.

This plan almost succeeded. When the United States entered World War I in April 1917, the U-boats were sinking merchant ships at an appalling rate. Existing defense measures—chiefly arming merchantmen and patrolling the ship lanes—were proving totally inadequate. The logical recourse was to convoy cargo ships in groups under armed escort, a device already tried and proved in the case of troopships. Now with American bases and naval reinforcements, a general convoy system became feasible and was successfully put into operation. In the intensified war against the U-boats, raids were carried out against the German submarine bases, mine fields were laid across the two Atlantic exits from the North sea, and acoustical devices were developed for detecting the presence of submerged U-boats. With the aid of these and other defensive measures, foodstuffs, raw materials and munitions continued to flow along the Atlantic sea lanes to the British Isles, across the channel to France and through the Mediterranean to Italy and the near east. A U.S. army, eventually 2,000,000 strong, was ferried safely across the Atlantic to the battlefields of Europe; and simultaneously the Allies drew steadily tighter the blockade of the Central Powers, which, starving their peoples and their war industries, prepared the way for their political and military collapse in 1918.

Post-World War I Developments.—The victory of 1918 completely altered the balance of naval forces in the Atlantic. The destruction of German sea power removed the threat which had chained the Royal Navy to European waters; which had suppressed the ancient antagonism of France and Britain; which had driven Great Britain and the U.S. into something approaching an alliance; and which had compelled the Royal Navy to relinquish without a struggle its primacy in the American seas. Temporarily at least, British sea power held exclusive and undisputed sway over the eastern Atlantic and adjoining narrow seas. And following the victory over Germany there were accumulating indications that British statesmen and their naval advisers looked forward to early restoration of their former global command of the seas.

This trend had disturbing repercussions on Anglo-U.S. relations. The war had caused an upsurge of navalism within the United States. Congress in 1916 had voted a construction program designed to give the United States a "navy second to none." Late in 1918 the administration had thrown its weight behind a supplementary building program which, if and when carried out, would have given the United States incomparably the strongest navy in the world. These mutually conflicting aims caused the close wartime association of Britain and the U.S. to cool rapidly after the Armistice. Anglo-U.S. relations began to show an alarming tendency to revert to their 19th-century pattern of mutual distrust and animosity.

One especially aggravating factor from the U.S. point of view was the continued existence of the Anglo-Japanese alliance. The reason for that pact had disappeared with the defeat of Germany, but neither party seemed willing to terminate it while the United States went on expanding its navy. U.S. statesmen, in turn, were just as unwilling to modify their naval plans as long as the Anglo-Japanese alliance remained in force, since its mere existence was felt to involve at least a theoretical possibility of simultaneous attack in two oceans.

The Washington conference for the limitation of armaments (1921–22) broke this deadlock. The Anglo-Japanese alliance was abrogated; naval building programs were drastically curtailed; a large number of older capital ships were scrapped; and the British, U.S. and Japanese battleship fleets were stabilized in the ratio of 5–5–3. The United States, in effect, recognized Britain's paramount strategic interest throughout the eastern Atlantic and European narrow seas. Britain, in turn, tacitly disavowed any intention of contesting United States control of the American seas.

The consequent improvement of Anglo-U.S. relations opened the way for a mutually advantageous redisposition of naval forces. The United States gradually shifted almost all its major fleet units to the Pacific. Britain postponed indefinitely the planned re-establishment of a battleship fleet in that ocean and concentrated British naval strength in European waters. Whether or not these dispositions reflected some definite understanding between the two governments, it is certain that the United States fleet came widely to be regarded as a symbol of Anglo-U.S. solidarity in the Pacific, and British sea power in European waters as the U.S. first line of defense in the Atlantic.

The Washington conference achieved no such happy solution of European naval problems. Irreconcilable differences between France and Britain on the one hand, and France and Italy on the other, appeared early in the negotiations. These differences grew out of the general failure to establish a stable power equilibrium in Europe after the war. At the outset it was largely an Anglo-French controversy. The British did not wholly share French fears of future aggression from a resurgent vengeful Germany. They believed rigorous repression of that country would seriously retard economic recovery. The prospect of French military hegemony over the continent aroused deep-seated opposition. The British ideal was still avoidance of military guarantees, a balance of power on the continent and a two-power naval standard for European waters.

No continental power was able, or even seriously disposed at that time, to contest Britain's two-power standard in the capital-ship category. But capital ships were no longer the only index of naval power. World War I had hastened the development of two new weapons which were to play an increasing role in the control of the seas, especially narrow seas such as the Mediterranean, the channel, and the North sea.

One of these new weapons, the submarine, had forced Britain to the brink of disaster, despite the Royal Navy's command of the ocean's surface. The other new weapon, the airplane, promised to develop into an even greater threat not only to shipping but also to the ports and industrial installations of the British Isles. The terms of peace prohibited Germany from possessing these newer weapons. But France suffered no such restriction and was geographically situated to use both submarines and planes against Britain with maximum effect. These weapons were consequently valuable diplomatic levers to be relinquished only in return for British guarantees to France. Moreover, if France were left to depend solely on its own defensive resources, a larger force of cruisers and destroyers would be required to ensure safe passage

across the Mediterranean for French colonial troops from Africa.

Another source of French intransigence was Italy's emergence as a serious contender for control of the Mediterranean. The Italian navy was decidedly inferior to that of France, but the Italian government insisted on the right to match France in every category of naval craft. Since Italy was exclusively a Mediterranean country, whereas France fronted on the Atlantic as well, to accept naval parity with Italy was equivalent, in French eyes, to surrendering control of the Mediterranean, and with it the assured flow of supply and reinforcements from Africa.

The French finally yielded with respect to capital ships and aircraft carriers, and in these two categories accepted parity with Italy and tonnage quotas low enough to preserve Britain's two-power standard for European waters. But every proposal to limit submarines and aircraft broke against the unsatisfied French demand for guarantees. Neither France nor Great Britain could agree on cruiser quotas acceptable to each other or to the other naval powers. The most that could be achieved was a qualitative restriction limiting individual cruisers to 10,000 tons displacement and 8-in. guns. Thus the way was left open for renewal of competitive warship construction.

The fascist revolution of 1922 provided just the stimulus needed to produce this result. To the fascists the Mediterranean was Italy's "mare nostrum." Mussolini boasted his determination to carve from its borderlands a modern counterpart of the classical Roman empire. Since control of the Mediterranean was an essential feature of his imperial pipe dream, Mussolini had no interest in naval limitation save as a means of cheaply improving Italy's naval position at the expense of France and Great Britain.

In 1927 the United States sponsored a second naval conference, called to deal specifically with the cruiser problem. Neither France nor Italy took any part in this conference which was thus foredoomed to failure. Its sessions, held at Geneva, quickly deteriorated into an Anglo-U.S. wrangle in which technical arguments and considerations were allowed to revive the ancient feud over freedom of the seas, and to recast the two great Atlantic powers in their abandoned roles of naval rivals and potential enemies.

A change of government in both countries inspired a fresh start. A third conference was held at London in 1930. Here some of the damage to Anglo-U.S. relations was repaired, and a provisional solution of the cruiser controversy was achieved. But the continued intransigence of France and Italy still prevented any stable adjustment of naval relations among the Atlantic and Mediterranean powers.

Likewise inimical to this end was the naval resurgence of Germany. Under the treaty of Versailles Germany was forbidden to acquire any modern armoured ship displacing over 10,000 tons. To circumvent this restriction, German naval architects created the so-called pocket-battleships, "Deutschland," "Admiral Scheer," and "Admiral Graf Spee." These ships, designed as commerce raiders, technically conformed to the Versailles limitation, but their 11-in. guns definitely outclassed the 8-in. weapons allowed on cruisers built by signatories of the Washington Naval treaty. These ships upset existing arrangements for the protection of commerce, compelled every Atlantic power to reconsider its naval program and in conjunction with other developments started a fresh cycle of competitive building.

One of these contributing causes was the Nazi revolution of 1933, followed by Hitler's denunciation of the Versailles treaty. Naval rearmament accelerated rapidly under the Nazis. Profiting from past experience, they concentrated mainly on commerce-raiding weapons. Their battle cruisers, "Scharnhorst" and "Gneisenau" (laid down in 1934), and even their great battleships, "Bismarck" and "Tirpitz" (1937), were conceived less as components of a massed fleet than as superraiders for attacking convoys on the high sea. The same objective was implicit in Germany's resumption of submarine building on a large scale. Yet in the face of these preparations manifestly directed primarily against Great Britain, Hitler won London's consent in 1935 to further German naval expansion up to 35% of British strength, with the possibility of eventual parity in submarines.

The Ethiopian crisis, later in 1935, focused attention on the deterioration which was taking place in the strategical position of France and Britain in the Mediterranean. Both London and Paris showed the greatest reluctance to take any steps which might force hostilities with Italy, and doubts were expressed in many quarters regarding the Royal Navy's continued ability to hold the Mediterranean against the air and sea power of Italy.

Formation of the Rome-Berlin axis in 1936 formally linked the growing danger in northern and in southern waters, and inclined the naval balance still more strongly against the Atlantic powers. But this event, followed by rapid deterioration of world conditions, provided the necessary stimulus for strenuous if tardy counter measures which were well under way when World War II intervened in Sept. 1939.

World War II.—The first phase of the ensuing battle for the Atlantic lasted until the fall of France in June 1940. During this period the Anglo-French coalition drove German merchant shipping from the Atlantic, and maintained a fairly effective long-range blockade on the general model of the previous war. The German-controlled zone in the North sea was somewhat broader than in 1914–18, mainly because of the maritime role now played by shore-based aviation. It was consequently more difficult to intercept German blockade-runners entering or leaving the North sea. The blockade in the Mediterranean also fell somewhat short, thanks to Italy's "nonbelligerent" help in forwarding sea-borne supplies to Germany. But these handicaps were offset by the close co-operation of the United States and other oversea countries in the use of various devices—pre-emptive buying, "navicerts," etc. —designed to cut at the source all traffic with the axis.

On the defensive side, the initial nonbelligerency of Italy postponed a showdown in the Mediterranean with resulting advantage to the Allies. Also the exclusion of axis men-of-war from a western hemisphere "safety zone," guarded by a "neutrality patrol" under United States leadership, afforded considerable protection to Allied shipping entering and leaving North and South American ports. On the other hand, the modern submarine proved to be a far more difficult weapon to combat than the primitive U-boats of 1918, and the Allies were dangerously short of antisubmarine equipment during the early months of the struggle. Early raids by the pocket-battleships, and threatened raids by the more formidable German battle cruisers, compelled the Allies to deplete their main fleets in order to provide battleship escort for their troop and cargo convoys. And the lengthening range of German air power, especially after the occupation of Norway, gradually curtailed British use of the North sea.

The battle for the Atlantic took a radically different turn following conquest of the Low Countries, the fall of France and Italy's entry into the war. Britain lost French naval support at the very moment when its own sea power was seriously crippled by losses incurred in the retreat from Narvik and evacuation from Dunkirk. The sea and air power of Italy, reinforced by German units, imperiled and eventually barred the direct route to Suez, forcing British shipping to use the long alternative route around the Cape of Good Hope. This cut the total cargo-carrying capacity of the British merchant marine almost in half at the very moment when German acquisition of naval and air bases on the channel and on the west coast of France foreshadowed more destructive attacks on shipping in northern waters.

At this critical juncture, the United States, though still technically a nonbelligerent, assumed a more positive role in the battle for the Atlantic. Fifty U.S. destroyers were turned over to Great Britain to make good previous naval losses. In return, the United States received long-term leases for ship and plane bases in Newfoundland, Bermuda and numerous points in the Caribbean. Congress voted a 70% increase in the navy, and early in 1941 a separate Atlantic fleet was established. U.S. units were sent to relieve the British garrison in Iceland, which had become a vital convoy depot and focus of antisubmarine activity. Greenland was occupied to provide additional facilities for the Anglo-U.S. sea and air patrol rapidly spreading over the north Atlantic. Transatlantic air-ferry service was developed for the delivery of planes and for the rapid transportation of important freight and personnel.

Early in 1942, after the United States had become a full belligerent, the axis opened a large-scale submarine offensive against coastal shipping in American waters. German U-boats also operated in considerable force along the south Atlantic ship lanes to India and the middle east. The Allied campaign (1942–43) to reopen the Mediterranean depended almost entirely upon sea-borne supply shipped through submarine-infested waters. Allied convoys approaching the British Isles, and those bound for the Russian ports of Murmansk and Archangel, had to battle their way against savage air and undersea attacks. It was publicly estimated at the close of 1942 that Allied shipping losses, chiefly from planes and U-boats, exceeded those suffered during the worst period of 1917. And a considerable weight of Allied naval power had to be kept constantly available in northern waters in case Germany's formidable surface raiders, especially the superbattleship "Tirpitz," should break into the Atlantic shipping lanes as the "Bismarck" did briefly in 1941.

On the other side of the ledger was the ever tightening Allied blockade of axis Europe and perceptible, if slow, progress in combating the axis war on shipping. With more and better equipment, the convoy system was strengthened and extended. Unprecedented ship building, especially in U.S. yards, caught up and began to forge ahead of losses, though the latter still remained dangerously high. Bombing raids on axis ports and industrial centres progressively impaired Germany's capacity to build and service submarines and aircraft. Transoceanic cargo planes provided for the United Nations an increasingly important alternative means of transport beyond the reach of enemy raiders. Brazil's entry into the war strengthened the Allied position in the south Atlantic. The occupation of virtually all west African ports, including the French naval bases at Casablanca and Dakar, denied to axis raiders their last possible havens in southern waters. By these and other means the Atlantic allies thwarted axis efforts to halt the passage of American armies and material to Europe and North Africa, to starve Britain into submission, to prevent supplies reaching the U.S.S.R. and to break up the blockade of axis Europe.

Victory in the Atlantic represented the collective effort of the United Nations, but chiefly of Britain, Canada and the United States. The strength of this coalition was derived in no small degree from the successful reintegration of the fundamental components of sea power: (1) a secure primary base, (2) superior resources and (3) favourable strategic position. Britain formerly possessed all three vis-à-vis both Europe and America. The rise of United States power coinciding with changing conditions in Europe had compelled Great Britain to recognize U.S. primacy in the western Atlantic. The tremendous industrial growth of Germany, coinciding with the development of submarines and later aircraft, undermined the security of England's island base off the coast of Europe, endangered the far-flung network of sea communications which supplied British industry, and thereby weakened the whole structure of British sea power. The United States lacked England's favourable strategical positions for offensive action vis-à-vis continental Europe. But the United States enjoyed a secure base thousands of miles from Europe and Asia. The United States also possessed resources and industrial potential surpassing those of any other country. Britain could no longer command the Atlantic singlehanded against a determined war on commerce backed up by the industrial resources of continental Europe. The United States, however, could not play Great Britain's historic role singlehanded. Together Britain and the U.S. combined, at least temporarily, the fundamental requisites for continued command of the Atlantic and adjoining narrow seas. Still it was by no means conclusive that even an Anglo-U.S. coalition could hold these waters indefinitely. The atomic bomb was not developed in time to play any role in the European-Atlantic phase of World War II. Nor did its use against Japanese cities demonstrate conclusively how nuclear weapons might affect the concepts of sea power in general, and command of the Atlantic in particular.

Post-World War II Developments.—Political realignments and technological advances following World War II posed unresolved issues regarding future control of the Atlantic. The U.S.S.R. stepped into the role previously played by Germany as challenger of Anglo-American primacy in the Atlantic. The Soviet government expanded its submarine force rapidly. New Russian submarines were believed to embody the latest design and to be more formidable craft than any operated in World War II. This development, together with the Soviet Union's rapid postwar industrial recovery, its unexpected upsurge in science and technology and the aggressive policies which characterized Stalin's last years, all combined to evoke countermeasures in the west. One of these was the North Atlantic alliance formed in 1949. NATO rested upon the premise, among others, that the nations fronting on the North Atlantic and connecting seas form a natural and viable defense community (*see* NORTH ATLANTIC TREATY ORGANIZATION).

This concept has an interesting background. One of the first to elaborate it in the context of sea power in the Atlantic was Sir Halford J. Mackinder (*q.v.*). This famous British geographer is better remembered for his earlier geopolitical hypothesis (formulated in 1904 and refined in 1919) that the layout of lands and seas favours the eventual rise of a dominant world power in the "heartland" of Eastern Europe and Inner Asia. In 1924, however, Mackinder propounded a counterhypothesis that strangely attracted very little attention. The essence of this counterhypothesis is that the potentialities of the Eurasian heartland could be balanced in the future by "Western Europe and North America," which (as Mackinder read the lessons of World War I) "constitute for many purposes a single community of nations." This geopolitical region, extending from the Volga river to the Rocky mountains of North America, he characterized (in 1931) as the "main geographical habitat of Western civilization." Within it he found all the ingredients of a great power constellation: over half a billion people, abundant natural resources, advanced technology, the most productive industrial regions, etc. "Notwithstanding the oceanic break it may be regarded as a single area," Mackinder argued, linked together as it is by the heavily traveled sea lanes of the North Atlantic which he significantly called the "Midland Ocean."

Mackinder's concept of the Atlantic community became a political reality in NATO. The concept's tenability has depended all along on ability of the NATO allies to maintain essential transatlantic traffic in the event of another world war. This issue poses two separable questions: Could Soviet submarines or other military forces fatally disrupt the flow of transatlantic traffic, as German submarines came close to doing in the two preceding wars? Would the initial blows and counterblows of an intercontinental war, fought with long-range nuclear weapons, leave any cargoes to ship, any usable ports through which to transport them or any surviving social organization to carry on at all? The technical aspects of Atlantic control in war are becoming ever more complex and uncertain. One reason is the development of nuclear-powered submarines capable of cruising submerged for weeks at a stretch. Another factor is the certainty that such craft can be armed with underwater-firing nuclear missiles capable of destroying distant ports and inland cities as well as shipping. The capacity of any nation to carry on effective armed conflict, or even survive as a nation, if its population and industrial centres were to suffer devastation from such missiles or other multimegaton nuclear weapons is even more uncertain and the subject of wide debate in the 1960s.

Meanwhile the Atlantic countries continue to depend heavily on sea-borne traffic. This traffic, because of its bulk and tonnage must be carried mainly in surface vessels, highly vulnerable to aerial bombs and submarine torpedoes. Half of Britain's food and most of its essential raw materials come from overseas. Western Europe as a whole is only slightly less dependent on transatlantic traffic. With progressive depletion of high-grade iron ore and other minerals within the United States, the American economy, too, grows yearly more dependent on raw materials shipped in by sea. As long as the nuclear stalemate continues (and it may continue indefinitely), traffic flows as usual along the Atlantic sea lanes to everyone's mutual advantage, the Communist countries included. What the situation might become in case of intercontinental nuclear war one can only speculate. But one can be reasonably confident that a future military battle

for the Atlantic, should it ever occur, would present difficulties far exceeding those that the western allies surmounted in the earlier world wars of the twentieth century. *See* also SEA POWER; WORLD WAR I; WORLD WAR II.

ATLANTIC CHARTER is the name given to a joint declaration, drawn up at a series of meetings on board warships in the North Atlantic in Aug. 1941, by Franklin D. Roosevelt, then president of the United States, and Winston Churchill, then prime minister of the United Kingdom. Conceived after the model of Woodrow Wilson's fourteen points, it was issued officially on Aug. 14 and stated in eight points certain common principles of United States and British policy on which the two leaders based their hopes for a better future for mankind after World War II.

The Atlantic Charter started with a solemn declaration that the two countries did not seek any aggrandizement. The next two points defined the right of all peoples to self-determination and self-government. The two leaders declared that "they desire to see no territorial changes that do not accord with the freely expressed wishes of the peoples concerned. They respect the right of all peoples to choose the form of government under which they will live; and they wish to see sovereign rights and self-government restored to those who have been forcibly deprived of them."

The fourth and fifth points concerned equality of access to the trade and raw materials of the world, and fullest collaboration between all nations in the economic field with the object of securing for all improved labour standards, economic adjustment and social security.

In the last three points, the two leaders recorded their hope "to see established a peace which will afford to all nations the means of dwelling in safety within their own boundaries, and which will afford assurance that all the men in all the lands may live out their lives in freedom from fear and want. . . Such a peace should enable all men to traverse the high seas and oceans without hindrance." The two leaders proclaimed that "all of the nations of the world . . . must come to the abandonment of the use of force."

Though it was incorporated by reference in the declaration by the United Nations of Jan. 1, 1942, the Atlantic Charter, like many other wartime declarations, was characterized more by vague generosity than by any precise commitment. Its significance lies less in its message than in the fact that the leaders of the two great North Atlantic democracies, which shared a common tradition of liberty and law, proclaimed common goals in conformity with these traditions and gained their acceptance as the aim of all the United Nations in prosecuting the war. ATLANTIC CITY, a city of Atlantic county, N.J., U.S.; a famous seaside resort on the Atlantic ocean, 55 mi. S.E. of Philadelphia, Pa., and 110 mi. S. by W. of New York City. Pop. (1960) 59,544; standard metropolitan statistical area (Atlantic county), 160,880. The Atlantic City standard metropolitan statistical area covers 575 sq.mi. and includes Hammonton, Pleasantville and Ventnor City. (For comparative population figures *see* table in NEW JERSEY: *Population.*)

The city lies on a low, sandy island (Absecon Island), 8.1 mi. long with varying widths of from one-tenth of a mile to 1.9 mi., separated from the mainland by a narrow strait and four or five miles of meadows which are partly covered with water at high tide.

Atlantic County.—Atlantic county was originally settled by whalers and oystermen. By the middle of the 18th century the bog iron industry flourished in its interior and shipyards lined the banks of its streams and bays, while the more secluded areas were haunts of pirates and, in time of war, privateers. Early in the following century the glass and textile industries were established there. The county has been crisscrossed by highways leading from Philadelphia to the shore towns and by the Garden State parkway which extends from New Jersey's northern boundary to Cape May at its southern tip. Vast farms raise blueberries, strawberries, apples, peaches, sweet potatoes, numerous varieties of vegetables, and poultry products.

The Boardwalk.—The possibilities of Absecon Island as a summer resort were first recognized by Jonathan Pitney, who settled there in 1820 to practice medicine. Three decades later he was the leader of a group which planned Atlantic City and induced the Camden and Atlantic railroad, later part of the Pennsylvania and Reading Seashore lines, to make the village its eastern terminus. The city was incorporated in 1854.

The first boardwalk was constructed in 1870 because of complaints of railroads and hotels about visitors' tracking sand onto their premises. The present boardwalk, built of steel and concrete with a wooden flooring, fifth to be built and completed in 1939, is 60 ft. wide and 4 mi. long. It is the centre of Atlantic City attractions. The first Easter parade took place there in 1876. A few years later the first of the amusement piers extending from it was constructed, the most famous and longest being Steel pier (2,000 ft. long), in operation since 1898.

Hotels not only line the boardwalk, but extend inland for several blocks. They range in size from small structures with only a few rooms to the large brick Chalfonte-Haddon hall with 1,000 rooms. Motels have become increasingly popular. Indoor-outdoor swimming pools, solariums and facilities for conferences and conventions at hotels and at Convention hall help Atlantic City to retain its position as a year-round tourist attraction. Each year it accounts for nearly half of all of the persons who visit New Jersey resorts.

The single event for which Atlantic City is most noted is the annual Miss America pageant. Established in 1921, it was discontinued in 1928 and revived in 1935 with a shift in emphasis from beauty to talent. College scholarships are included among awards given to "Miss America" and other prize winners. (E. R. D.)
